Adversarially Robust Models may not Transfer Better: Sufficient Conditions for Domain Transferability from the View of Regularization

Xiaojun Xu *1 Jacky Yibo Zhang *1 Evelyn Ma 1 Danny Son 1 Oluwasanmi Koyejo 1 Bo Li 1

Abstract

Machine learning (ML) robustness and domain generalization are fundamentally correlated: they essentially concern data distribution shifts under adversarial and natural settings, respectively. On one hand, recent studies show that more robust (adversarially trained) models are more generalizable. On the other hand, there is a lack of theoretical understanding of their fundamental connections. In this paper, we explore the relationship between regularization and domain transferability considering different factors such as norm regularization and data augmentations (DA). We propose a general theoretical framework proving that factors involving the model function class regularization are sufficient conditions for relative domain transferability. Our analysis implies that “robustness” is neither necessary nor sufficient for transferability; rather, regularization is a more fundamental perspective for understanding domain transferability. We then discuss popular DA protocols (including adversarial training) and show when they can be viewed as the function class regularization under certain conditions and therefore improve generalization. We conduct extensive experiments to verify our theoretical findings and show several counterexamples where robustness and generalization are negatively correlated on different datasets.

1. Introduction

Domain generalization (or domain transferability) is the task of training machine learning models with data from one or more source domains that can be adapted to a target domain, often via low-cost fine-tuning. Thus, domain generalization refers to approaches designed to address the natural data distribution shift problem (Muandet et al., 2013; Rosenfeld et al., 2021). A wide array of approaches have been proposed to address domain transferability, including fine-tuning the last layer of DNNs (Huang et al., 2018), invariant feature optimization (Muandet et al., 2013), efficient model selection for fine-tuning (You et al., 2019), and optimal transport based domain adaptation (Courty et al., 2016). Understanding domain generalization has emerged as an important task in the machine learning community.

On the other hand, robust machine learning aims to tackle the problem of adversarial data distribution shift. Both empirical and certified robust learning approaches have been proposed, such as empirical adversarial training (Madry et al., 2018) and certified defenses based on both deterministic and probabilistic approaches (Cohen et al., 2019; Li et al., 2019; 2021; 2020).

Recent studies (Salman et al., 2020; Utrera et al., 2020) draw a connection between domain transferability and robustness, and suggest that adversarially robust models (i.e., models with good accuracy under adversarial attacks) are more domain transferable. However, a theoretical analysis of their fundamental connections is still lacking, and it is unclear whether robustness is necessary or sufficient. To fill in this gap, this paper aims to answer the following questions: Is model robustness sufficient or necessary for domain transferability? What are sufficient conditions for domain transferability?

To answer the first question, our analysis and experiments show that adversarial robustness is neither sufficient nor necessary for domain transferability and they can even be negatively correlated. To answer the second question, we first observe that domain transferability is fundamentally a “relative” concept, as it by definition involves two domains, i.e., the source/target domain. With the observation, we propose a general theoretical framework that characterizes sufficient conditions for the relative domain transferability from the view of function class regularization. The relative domain transferability, loosely speaking, is the performance of the fine-tuned source model on the target domain relative
to the performance of the source model on the source domain. We then prove an inequality showing that stronger regularization on the feature extractor (during the source model training process) implies a better relative domain transferability. We also discuss what data augmentations can be viewed as function class regularization generally. Since adversarial training can be viewed as a regularization under some conditions (Roth et al., 2020; El Ghaoui & Lebret, 1997; Bertsimas & Copenhaver, 2018), our work implies that the regularization effect of adversarial training is a better and more fundamental explanation for the connection between adversarial training and domain transferability.

To verify our theory, we conduct extensive experiments on ImageNet (CIFAR-10 as target domain) and CIFAR-10 (SVHN as target domain) based on different models. We show that regularizations such as norm regularization and certain data augmentations can control the relative and absolute domain transferability, while the robustness and domain transferability can be even negatively correlated with the domain transferability, as illustrated in Fig. 1.

**Technical contributions.** Our theoretical analysis and empirical findings show that, instead of robustness or adversarial training, regularization is a more fundamental perspective to understand domain transferability. Concretely,

- We show that improving adversarial robustness is neither necessary nor sufficient for improving domain transferability without additional conditions, as shown in Section 2.1.
- We propose a theoretical framework to analyze the sufficient conditions for domain transferability from the view of function class regularization (Section 2.2&2.3). We prove that shrinking the function class of feature extractors during training monotonically decreases a tight upper bound on the relative domain transferability loss. Therefore, it is reasonable to expect that imposing regularization on the feature extractor during training can lead to a better relative domain transferability.
- We provide general analysis on when data augmentations (including adversarial training) can be viewed as regularization. In particular, we verify analysis based on the data augmentations of Gaussian noise, rotation, and translation, as discussed in Section 3.
- We conduct extensive experiments on different datasets and model architectures to verify our theoretical claims (Section 4). We also show counterexamples where adversarial robustness is significantly negatively correlated with domain transferability.

Taken together, our results suggest a more nuanced explanation of the phenomenon that “adversarially trained models transfer better,” suggesting instead that adversarial training implies training with regularization, which, in turn, implies better transferability. As a consequence, although adversarial training implies better adversarial robustness, better adversarial robustness does not necessarily imply better transferability.

**Related Work.** Domain Transferability has been analyzed in different settings. Muandet et al. (2013) present a generalization bound for classification tasks based on the properties of the assumed prior over training environments. Rosenfeld et al. (2021) model domain transferability/generalization as an online game and show that generalizing beyond the convex hull of training environments is NP-hard. Given the complexity of domain transferability analysis, recent empirical studies observe that adversarially trained models transfer better (Salman et al., 2020; Utrera et al., 2020).

Model robustness is an important topic given recent diverse adversarial attacks (Goodfellow et al., 2014; Carlini & Wagner, 2017). These attacks may be launched without access to model parameters (Tu et al., 2019) or even with the model predictions alone (Chen et al., 2020a). Different approaches have been proposed to improve model robustness against adversarial attacks (Yang et al., 2021; Ma et al., 2018; Xiao et al., 2018). Adversarial training has been shown to be effective empirically (Madry et al., 2018; Zhang et al., 2019; Miyato et al., 2018). Some studies have shown that robustness is related to other model characteristics, such as...
transferability and invertibility (Engstrom et al., 2019; Liang et al., 2020). A recent work (Deng et al., 2021) theoretically analyzes how adversarial training helps transfer learning. Although their proof implicitly depends on regularization, the authors only focus on adversarial training for linear models, while we directly focus on regularization for general models (e.g., DNNs).

2. Sufficient Conditions for Domain Transferability

In this section, we theoretically analyze the problem of domain transferability from the view of regularization and discuss some sufficient conditions for good transferability. All of the proofs are provided in Section A in the appendix.

Notations. We denote the input space as $\mathcal{X}$; the feature space as $\mathcal{Z}$ and the output space as $\mathcal{Y}$. Let the fine-tuning function class be $g \in \mathcal{G}$. Given a feature extractor $f : \mathcal{X} \to \mathcal{Z}$ and a fine-tuning function $g : \mathcal{Z} \to \mathcal{Y}$, the full model is $g \circ f : \mathcal{X} \to \mathcal{Y}$. We denote $\mathcal{P}_{\mathcal{X} \times \mathcal{Y}}$ as the set of distributions on $\mathcal{X} \times \mathcal{Y}$. The loss function on $\mathcal{Y}$ is denoted by $\ell : \mathcal{Y} \times \mathcal{Y} \to \mathbb{R}_+$. The population loss function based on data distribution $D \in \mathcal{P}_{\mathcal{X} \times \mathcal{Y}}$ and a model $g \circ f$ is defined as

$$
\ell_D(g \circ f) := \mathbb{E}_{(x,y) \sim D}[\ell(g \circ f(x), y)].
$$

In the following, we first provide an example to show that the robustness can be irrelevant to domain transferability and to illustrate why one might investigate domain transferability from the view of regularization.

2.1. A Toy Example: Motivation and Intuition

In this subsection, we construct a simple example where improving adversarial robustness is neither necessary nor sufficient for improving (relative) domain transferability, yet stronger regularization sufficiently improves relative domain transferability. The settings introduced in this subsection are only applied in this subsection.

We consider the case that $\mathcal{X} = \mathbb{R}^m$ and $\mathcal{Y} = \mathbb{R}^d$. Given an input $x \in \mathcal{X}$, the ground truth target for the source domain is $y_S(x)$ generated by a function $y_S : \mathbb{R}^m \to \mathbb{R}^d$. Similarly, we define $y_T$ for the target domain. In this example, for simplicity, we neglect the fine-tuning process but directly consider learning a function $f : \mathbb{R}^m \to \mathbb{R}^d$ with a norm $\| \cdot \|$ on $\mathbb{R}^d$. We note that the analysis in this subsection holds with any choice of norm on $\mathbb{R}^d$.

Given the source and target distributions $D_S$, $D_T \in \mathcal{P}_{\mathcal{X} \times \mathcal{Y}}$, we consider the case that their marginal distributions on the input space $\mathcal{X}$ are both $D$, while $y_S$ and $y_T$ could be different. Moreover, we consider the case that the support of the input data distribution $D$ lies on a low-dimensional manifold $\mathcal{M} \subset \mathcal{X} = \mathbb{R}^m$ such that for all $x \in \mathcal{M}$, any Euclidean ball centered at $x$ has non-empty intersection with $\mathbb{R}^m \setminus \mathcal{M}$. Given the distribution $D$, we define a norm for functions $f : \mathbb{R}^m \to \mathbb{R}^d$ as $\| f \|_D := \mathbb{E}_{x \sim D}[\| f(x) \|]$, where we view two functions $f_1$, $f_2$ as the same if $\| f_1 - f_2 \|_D = 0$. Therefore, given a model $f$, for the source domain and the target domain we consider the respective loss functions as

$$
\ell_D(f) = \mathbb{E}_{x \sim D}[\| f(x) - y_S(x) \|] = \| f - y_S \|_D,
$$

$$
\ell_D(f) = \mathbb{E}_{x \sim D}[\| f(x) - y_T(x) \|] = \| f - y_T \|_D.
$$

The toy example serves two purposes: (1) supporting the “neither necessary nor sufficient” claim; and (2) motivating the perspective of regularization. For the first purpose, the main intuition is that we can construct a setting where the domain transferability is only evaluated on a low-dimensional manifold while the adversarial robustness is only evaluated off the manifold. In such cases, a model having better adversarial robustness does not imply it has better domain transferability, and similarly a model having better domain transferability does not imply it has better adversarial robustness. For the second purpose, as illustrated in Figure 2, regularization is related to the domain transferability in this toy example. This motivates the general study of the relationship between regularization and domain transferability in Section 2.2.

Robustness is neither necessary nor sufficient for domain transferability. We may see the relation between adversarial robustness and domain transferability in this example as follows. Given a source model $f_{D_S} : \mathbb{R}^m \to \mathbb{R}^d$, we consider the adversarial loss on an input $x \in \mathcal{M}$, i.e.,

$$
\ell_{adv}(x; f_{D_S}) := \max_{\delta : \| \delta \|_2 \leq \epsilon} \ell(f_{D_S}(x + \delta), y_S(x)),
$$

as an indicator of its robustness on the input $x$ on the source domain. The lower the adversarial loss, the better the robustness. We can see that both the regular loss functions $\ell_D(f_{D_S})$ and $\ell_{D_S}(f_{D_S})$ only evaluate $f_{D_S}$ on the low-dimensional manifold $\mathcal{M}$. Therefore, an adversarial perturbation $\delta \in \mathbb{R}^m$ could make $x + \delta \notin \mathcal{M}$ if the loss value is sufficiently high in $\{ x + \delta : \| \delta \|_2 \leq \epsilon \} \setminus \mathcal{M}$. As a result, in such cases the adversarial loss $\ell_{adv}(x; f_{D_S})$ could be arbitrarily high without affecting either the source domain performance $\ell_D(f_{D_S})$ or the target domain performance $\ell_D(f_{D_S})$, i.e., without affecting their transferability. This implies that improving adversarial robustness is neither necessary nor sufficient for improving domain transferability.

The toy example illustrates that robustness can be irrelevant to domain transferability, and then the question one may naturally ask is “what may have a stronger relevance to domain transferability?” To provide the intuition that regularization may be the key, we make the following analysis using the same toy example.

Intuition on why regularization matters. Denoting a function space $\mathcal{F} = \{ f : \mathbb{R}^m \to \mathbb{R}^d \mid \| f \|_D < \infty \}$, we
assume $y_S, y_T \in \mathcal{F}$ such that we can compare $f, y_S, y_T$ in the same space. Therefore, given $c > 0$ as a regularization parameter, we define the domain transferability problem as:

Learning a source model:

$$f^D_S \in \arg \min_{f \in \mathcal{F}} \ell_{D_S}(f), \quad \text{s.t. } \|f\|_D \leq c; \quad (2)$$

Testing on a target domain:

$$\ell_{D_T}(f^D_S),$$

where the minimizer is $f^D_S := y_S \min \{1, \frac{c}{\|y_T\|_D}\}$, the source domain loss is $\ell_{D_S}(f) = \|f - y_S\|_D$, and the target domain loss is $\ell_{D_T}(f) = \|f - y_T\|_D$. We prove in Proposition 2.1 that $f^D_S$ is indeed a minimizer of equation 2.

Considering the relation between (relative) domain transferability and the regularization parameter $c$, we have an interesting finding. An illustration of the finding is shown in Figure 2, and a more formal statement is provided in Proposition 2.1. As we can see, the relation between regularization and domain transferability is clear if we consider the domain transferability in a “relative” way, i.e., the loss value on the target domain minus the loss value on the source domain. A formal definition of the relative transferability loss is deferred to Definition 2.2 in the next subsection.

**Proposition 2.1.** Given the toy example problem defined in Section 2.1, $f^D_S$ is a minimizer of equation 2. If $c \geq c' \geq 0$, then the relative domain transferability loss $\ell_{D_T}(f^D_S) = \ell_{D_S}(f^D_{c'}) - \ell_{D_S}(f^D_{c}) \geq \ell_{D_T}(f^D_S) \geq \ell_{D_S}(f^D_{c'}) - \ell_{D_S}(f^D_{c})$.

As we can see from this toy example, robustness is neither necessary nor sufficient to characterize domain transferability. However, there is a monotone relation between the regularization strength and the relative domain transferability loss. Although the above proposition is derived specifically for the toy example, similar behavior is also observed in our experiments. Naturally, these findings motivate the study of the connections between the regularization of the training process and domain transferability in general, as we consider next.

### 2.2. Upper Bound of Relative Domain Transferability

In this subsection, we consider the general transferability problem with fine-tuning. We prove that there is a monotone decreasing relationship between the regularization strength and a tight upper bound on the relative domain transferability loss. Given a training algorithm $A$, it takes a data distribution $D$ and outputs a feature extractor $f^A_D \in \mathcal{F}_A$ chosen from a function class $\mathcal{F}_A$ as well as a feature-tuning function $g^D_A \in \mathcal{G}$. First, we formally define the relative domain transferability loss.

**Definition 2.2 (Relative Domain Transferability Loss).** Given the training algorithm $A$ and a pair of distributions $D_S, D_T \in \mathcal{P}_{X \times Y}$, the relative domain transferability loss between $D_S, D_T$ is defined to be the difference of fine-tuned losses, i.e.,

$$\tau(A; D_S, D_T) := \inf_{g \in \mathcal{G}} \ell_{D_T}(g \circ f^D_S) - \ell_{D_S}(g^D_A \circ f^D_S).$$

As we can see, when $\ell_{D_S}(g^D_A \circ f^D_S)$ is the same, smaller $\tau(A; D_S, D_T)$ means the better performance on the target domain.

Another perspective of Definition 2.2 is that $\inf_{g \in \mathcal{G}} \ell_{D_T}(g \circ f^D_S) = \ell_{D_S}(g^D_A \circ f^D_S) + \tau(A; D_S, D_T)$. From this perspective, the transferred loss is the source loss plus an additional term to be upper bounded by a certain distance metric between the source and target distributions – as is common in the literature of domain adaptation (e.g., \cite{ben2007analysis, chen2017domain}). The key question of the “distance metric” remains unanswered. To this end, we propose the following.

**Definition 2.3 ((\(\mathcal{G}, \mathcal{F}\))-pseudometric).** Given a fine-tuning function class $\mathcal{G}$, a feature extractor function class $\mathcal{F}$ and distributions $D_S, D_T \in \mathcal{P}_{X \times Y}$, the ($\mathcal{G}, \mathcal{F}$)-pseudometric between $D_S, D_T$ is

$$d_{\mathcal{G}, \mathcal{F}}(D_S, D_T) := \sup_{f \in \mathcal{F}} \inf_{g \in \mathcal{G}} |\ell_{D_S}(g \circ f) - \ell_{D_T}(g \circ f)|.$$

Since the fine-tuning function class is usually simple and fixed, we will use $d_{\mathcal{F}}$ as an abbreviation when $\mathcal{G}$ is clear.
It can be easily verified that \( d_{g,F} \) is a pseudometric that measures the distance between two distributions, as shown in the following proposition.

**Proposition 2.4.** \( d_{g,F}(\cdot,\cdot) : \mathcal{P}_{X \times Y} \times \mathcal{P}_{X \times Y} \to \mathbb{R}_+ \) satisfies the following properties.

1. (Symmetry) \( d_{g,F}(D_S,D_T) = d_{g,F}(D_T,D_S) \).
2. (Triangle Inequality) For \( \forall D' \in \mathcal{P}_{X \times Y} \), we have \( d_{g,F}(D_S,D_T) \leq d_{g,F}(D_S,D') + d_{g,F}(D',D_T) \).
3. (Weak Zero Property) For \( \forall D \in \mathcal{P}_{X \times Y} \): \( d_{g,F}(D,D) = 0 \).

The motivation of the \((G,F)\)-pseudometric comes from the following observations. We want to study what factors affect how a source model transfers to the target domain. The obvious factor is the difference between the two domains. But the function class where the model is trained from is also an important factor (e.g., the example in Section 2.1). Note that the proposed \((G,F)\)-pseudometric is both a complexity measure of the model function class and a distance measure of two distributions. Given a certain fixed function class, the \((G,F)\)-pseudometric can serve as a distance measure related to the Wasserstein distance or the total variance distance.

In section A.3 in the appendix, we show that, if the loss function is Lipschitz, then the \((G,F)\)-pseudometric between \( D_S \) and \( D_T \) is upper bounded by the product of the Lipschitz constant and the Wasserstein distance between \( D_S \) and \( D_T \). Moreover, in proposition A.4 in the appendix, we show that the total variation distance upper bounds the \((G,F)\)-pseudometric if we are working in the realm of multi-class classification and the loss function is the 0-1 loss.

The major difference of the \((G,F)\)-pseudometric with existing metrics for domain transfer (Ben-David et al., 2010; Mansour et al., 2009; Acuna et al., 2021; Zhao et al., 2019) is that the proposed \((G,F)\)-pseudometric is more general. Concretely, the aforementioned work only considers the distributions on the input space \( X \), while we consider both the input space and the output space, i.e., \( X \times Y \). This difference enables us to consider the fine-tuning process, which is important and widely applied in practice.

In this section, we consider a fixed fine-tuning function class \( \mathcal{F}_A \) given by the training algorithm \( A \). Thus, we denote \( d_{g,F} \) as \( d_{F_A} \) for the remainder of the paper. With the definition of \( d_{F_A} \), we can derive the following result which provides justification for the regularization perspective.

**Theorem 2.5.** Given a training algorithm \( A \), for \( \forall D_S,D_T \in \mathcal{P}_{X \times Y} \) we have

\[
\tau(A;D_S,D_T) = d_{F_A}(D_S,D_T), \quad \text{or equivalently,} \quad \inf_{g \in \mathcal{G}} \ell_{D_T}(g \circ f_D^A) \leq \ell_{D_S}(g \circ f_D^A) + d_{F_A}(D_S,D_T).
\]

**Interpretation:** As we can see, the above theorem provides sufficient conditions for good domain transferability. There is a monotone relation between the regularization strength and \( d_{F_A}(D_S,D_T) \), i.e., the upper bound on the relative domain transferability loss \( \tau(A;D_S,D_T) \). More explicitly, if a training algorithm \( A' \) has \( \mathcal{F}_{A'} \subseteq \mathcal{F}_A \), then \( d_{F_A}(D_S,D_T) \leq d_{F_{A'}}(D_S,D_T) \). Moreover, small \( d_{F_A}(D_S,D_T) \) implies good relative domain transferability. From this perspective, we can see that we need both small \( d_{F_A}(D_S,D_T) \) and small source loss \( \ell_{D_S}(g_A^D \circ f_A^D) \) to guarantee good absolute domain transferability. Note that there is a possible trade-off, i.e., with \( \mathcal{F}_A \) being smaller, \( d_{F_A}(D_S,D_T) \) decreases but possibly \( \ell_{D_S}(g_A^D \circ f_A^D) \) increases due to the limited power of \( \mathcal{F}_A \). On the other hand, there may not be such trade-off if \( D_S \) and \( D_T \) are close enough such that \( d_{F_A}(D_S,D_T) \) is small.

To make the upper bound more meaningful, we need to study its tightness.

**Theorem 2.6.** Given any source distribution \( D_S \in \mathcal{P}_{X \times \mathbb{R}^d} \), any finite-tuning function class \( \mathcal{G} \) where \( \mathcal{G} \) includes the zero function, we assume the training algorithm \( A \) is optimal, i.e., \( \ell_{D_S}(g_A^D \circ f_A^D) = \inf_{g \in \mathcal{G}} \ell_{D_S}(g \circ f_D) \). We assume some properties of the loss function \( \ell : \mathbb{R}^d \to \mathbb{R}^d \): it is differentiable and strictly convex w.r.t. its first argument; \( \ell(y,y) = 0 \) for any \( y \in \mathbb{R}^d \); and \( \lim_{y \to \infty} \inf_{y_0} \ell(y_0, y) = \infty \), where \( 0 \) is the zero vector. Then, given any distribution \( D_X^\prime \) on \( X \), there exist some distributions \( D_T \in \mathcal{P}_{X \times \mathbb{R}^d} \) with its marginal on \( X \) being \( D_X^\prime \) such that

\[
\tau(A;D_S,D_T) = d_{F_A}(D_S,D_T), \quad \text{or equivalently,} \quad \inf_{g \in \mathcal{G}} \ell_{D_T}(g \circ f_D^A) = \ell_{D_S}(g_A^D \circ f_A^D) + d_{F_A}(D_S,D_T).
\]

**Interpretation:** In the above theorem, we show that given any \( A, D_S \), and the marginal \( D_X^\prime \), there exist some conditional distributions of \( y|x \) such that by composing it with the given \( D_X^\prime \) we have a distribution \( D_T \) where the equality holds in Theorem 2.5. The optimality assumption on the training algorithm is mild, as it is common for modern neural networks to achieve considerably low loss. Nonetheless, a generalized version of the theorem is provided as Theorem A.7 in the appendix which works with any training algorithm. Alternative form of the tightness analysis is discussed immediately after the proof of Theorem A.7.

Therefore, we prove that stronger regularization on the feature extractor implies a decreased tight upper bound on the relative transferability loss. For a cleaner presentation, the analysis so far does not consider the potential influence from finite samples which for sure affects domain generalization. In the next subsection, we investigate the proposed theory on relative transferability with finite samples.
2.3. Generalization Upper Bound of the Relative Domain Transferability

For a distribution \( \mathcal{D} \in \mathcal{P}_{X \times Y} \), we denote its empirical distribution with \( n \) samples as \( \mathcal{D}^n \). That being said,

\[
\ell_{\mathcal{D}^n}(g \circ f) = \mathbb{E}_{(x,y) \sim \mathcal{D}^n}[\ell(g \circ f(x), y)] = \frac{1}{n} \sum_{i=1}^{n} \ell(g \circ f(x_i), y_i),
\]

where \((x_i, y_i)\) are i.i.d. samples from \( \mathcal{D} \). Therefore, given two distributions \( \mathcal{D}_S, \mathcal{D}_T \in \mathcal{P}_{X \times Y} \), the empirical \((\mathcal{G}, \mathcal{F})\)-pseudo metric between them is \( d_{\mathcal{G}, \mathcal{F}}(\mathcal{D}_S^n, \mathcal{D}_T^n) \).

Note that \( d_{\mathcal{G}, \mathcal{F}} \) is not only a pseudometric of distributions, but also a complexity measure, and we will first connect it with the Rademacher complexity.

**Definition 2.7** (Empirical Rademacher Complexity (Bartlett & Mendelson, 2002; Koltchinskii, 2001)). Denote the loss function class induced by \( \mathcal{G}, \mathcal{F} \) as

\[
\mathcal{L}_{\mathcal{G}, \mathcal{F}} := \{ h_{g,f} : X \times Y \to \mathbb{R}_+ \mid g \in \mathcal{G}, f \in \mathcal{F} \},
\]

where \( h_{g,f}(x,y) := \ell(g \circ f(x), y) \).

Given an empirical distribution \( \mathcal{D}^n \) (i.e., \( n \) data samples), the Rademacher complexity of it is

\[
\text{Rad}_{\mathcal{D}^n}(\mathcal{L}_{\mathcal{G}, \mathcal{F}}) := \frac{1}{n} \mathbb{E}_{\xi} \left[ \sup_{h \in \mathcal{L}_{\mathcal{G}, \mathcal{F}}} \sum_{i=1}^{n} \xi_i h(x_i, y_i) \right],
\]

where \( \xi \in \mathbb{R}^n \) are Rademacher variables, i.e., each \( \xi_i \) is i.i.d. uniformly distributed on \((-1, 1)\).

We can see that if there is a \( \mathcal{F}' \subseteq \mathcal{F} \), then \( \text{Rad}_{\mathcal{D}^n}(\mathcal{L}_{\mathcal{G}, \mathcal{F}')} \leq \text{Rad}_{\mathcal{D}^n}(\mathcal{L}_{\mathcal{G}, \mathcal{F}}) \). With the above definitions, we have the following lemma connecting the \((\mathcal{G}, \mathcal{F})\)-pseudo metric to Rademacher complexity.

**Lemma 2.8.** Assuming the loss function \( \ell : \mathcal{Y} \times \mathcal{Y} \to [0, c] \), given any distribution \( \mathcal{D} \in \mathcal{P}_{X \times Y} \) and \( \forall \delta > 0 \), with probability \( 1 - \delta \) we have

\[
d_{\mathcal{G}, \mathcal{F}}(\mathcal{D}, \mathcal{D}^n) \leq 2\text{Rad}_{\mathcal{D}^n}(\mathcal{L}_{\mathcal{G}, \mathcal{F}}) + 3\sqrt{\frac{\ln(4/\delta)}{2n}}.
\]

Therefore, denoting again \( d_{\mathcal{F}} \) as \( d_{\mathcal{G}, \mathcal{F}^*} \), the empirical version of Theorem 2.5 is as follows.

**Theorem 2.9.** Assuming the loss function \( \ell : \mathcal{Y} \times \mathcal{Y} \to [0, c] \), given \( \forall \mathcal{D}_S, \mathcal{D}_T \in \mathcal{P}_{X \times Y} \), for \( \forall \delta > 0 \) with probability \( 1 - \delta \) we have

\[
\tau(A; \mathcal{D}_S^n, \mathcal{D}_T^n) \leq d_{\mathcal{F}^*}(\mathcal{D}_S^n, \mathcal{D}_T^n) + 2\text{Rad}_{\mathcal{D}^n}(\mathcal{L}_{\mathcal{G}, \mathcal{F}^*}) + 4\text{Rad}_{\mathcal{D}^n}(\mathcal{L}_{\mathcal{G}, \mathcal{F}^*}) + 9c\sqrt{\frac{\ln(8/\delta)}{2n}}.
\]

3. When Can Data Augmentation be Viewed as Regularization?

In this section, we discuss the connections between data augmentation (DA) and regularization. We present the results and their interpretation in this section, while deferring the detailed discussion and comparisons with related work to Section B in the appendix.

**General settings.** We consider the fine-tuning function \( g : \mathbb{R}^d \to \mathbb{R} \) as a linear layer, which will be concatenated to the feature extractor \( f : \mathbb{R}^m \to \mathbb{R}^d \). Given a model \( g \circ f \), we use the squared loss \( \ell(g \circ f(x), y) = (g \circ f(x) - y)^2 \), and accordingly apply second-order Taylor expansion to the objective function to study the effect of data augmentation.

**DA categories.** We discuss two categories of DA, the feature-level DA and the data-level DA. The feature-level DA (Wong et al., 2016; DeVries & Taylor, 2017) requires the transformation to be performed in the learned feature space: given a data sample \( x \in \mathbb{R}^m \) and a feature extractor \( f \), the augmented feature is \( W_* f(x) + b_* \), where \( W_* \in \mathbb{R}^{d \times d}, b_* \in \mathbb{R}^d \) are sampled from a distribution.

On the other hand, the data-level DA requires the transformation to be performed in the input space: given a data sample \( x \), the augmented sample is \( W_* x + b_* \), where \( W_* \in \mathbb{R}^{m \times m}, b_* \in \mathbb{R}^m \) are sampled from a distribution.

**Intuition on sufficient conditions.** For either the feature-level or the data-level DA, the intuitions given by our analysis are similar. Our results (Theorem B.1.B.2) suggest that the following conditions indicate regularization effects of a data augmentation: 1) \( \mathbb{E}_{W_*}[W_*] = I \); 2) \( \mathbb{E}_{b_*}[b_*] = 0 \); 3) \( W_* \) and \( b_* \) are independent, where \( I \) is the identity matrix and \( 0 \) is the zero vector; 4) \( W_* \) is not a constant if it is the feature-level DA; 5) \( DA \) is of a small magnitude if it is the data-level DA.

**Empirical verification.** Combining with Theorem 2.9, it suggests that DA satisfying the conditions above may improve the relative domain transferability. In fact, it matches...
the empirical observations in Section 4. Concretely, 1) **Gaussian noise satisfies** the four conditions, and empirically the Gaussian noise improves domain transferability while robustness decreases a bit (Figure 5); 2) **Rotation**, which rotates input image with a predefined fixed angle with predefined fixed probability, violates $E_{W_s}[W_s] = I$, and empirically the rotation barely affects domain transferability (Figure 7); 3) **Translation**, which moves the input image for a predefined distance along a pre-selected axis with fixed probability, violates $E_{b_s}[b_s] = 0$, and empirically the translation distance barely co-relates to the domain transferability (Figure 7).

**Adversarial training.** It is known that adversarial training, a special kind of data augmentation, can be viewed as regularization in some scenarios (Roth et al., 2020). We further prove that, under certain conditions, adversarial training reduces the size of the feature extractors function class during training (see Section C for details). Therefore, our theoretical analysis implies that adversarial training helps domain transferability from its regularization effect.

4. **Evaluation**

4.1. **Experimental Setting**

**Source model training.** We train our model on two source domains: CIFAR-10 and ImageNet. Unless specified, we will use the training settings as follows. For CIFAR-10, we train the model with 200 epochs using the momentum SGD optimizer with momentum 0.9, weight decay 0.0005, an initial learning rate 0.1 which decays by a factor of 10 at the 100-th and 150-th epoch. For ImageNet, we train the model with 90 epochs using the momentum SGD optimizer with momentum 0.9, weight decay 0.0001, an initial learning rate 0.1 which decays by a factor of 10 at the 30-th and 60-th epoch. We use the standard cross-entropy loss denote as $L_{CE}(h_s, x, y)$, where $h_s = g_s \circ f$ is the trained model and $x, y$ are the input and label respectively. For both tasks, we use ResNet-18 as the model architecture. We provide results of other model structures in Appendix D.3.

**Model robustness evaluation.** To evaluate the model robustness on the source domain, we will show the model accuracy under adversarial attack. We follow the evaluation setting in (Ilyas et al., 2019) and perform the PGD attack with 20 steps using $\epsilon = 0.25$. This empirical robust accuracy reflects how well the model performs under adversarial attack, which is the adversarial loss as in equation 1 if we view $\ell(\cdot, \cdot)$ as the 0-1 loss between prediction and ground truth. We also provide robustness evaluation with AutoAttack in Appendix D.4.

**Domain transferability.** We evaluate the transferability from CIFAR-10 to SVHN and from ImageNet to CIFAR-10. For the ImageNet, we focus on CIFAR as the target domain, since it is the domain that is the most positively correlated with robustness as shown in (Salman et al., 2020). We evaluate the fixed-feature transfer where only the last fully-connected layer is fine-tuned following our theoretical framework. We fine-tune the last layer with 40 epochs using SGD with momentum 0.9, weight decay 0.0005, an initial learning rate 0.01 which decays by a factor of 10 at the 20-th and 30-th epoch. To mitigate the impact of benign accuracy, we evaluate the relative domain transfer accuracy (DT Acc) as follows. Let $acc_{src}$ and $acc_{tgt}$ be the accuracy of the fine-tuned model on the source and target domain, and $acc_{src}^v$ and $acc_{tgt}^v$ be the accuracy of vanilla model (i.e., models trained with standard settings) on source and target domain, then the relative DT accuracy is defined as:

$$\text{DT Acc} = \left( acc_{tgt} - acc_{src} \right) - \left( acc_{tgt}^v - acc_{src}^v \right).$$

Note that by definition, we can directly use $acc_{tgt} - acc_{src}$ as the relative accuracy. We use a relative score $(acc_{tgt} - acc_{src})$ so that the positive/negative values reflect the comparison with the vanilla-trained model. We also provide the results of absolute DT accuracy in Appendix D.1.

4.2. **Relationship between Robustness and Transferability Under Controllable Conditions**

We train the model under different controllable conditions to validate our analysis. In particular, we train the methods by controlling different regularization or data augmentations to evaluate the model robustness and transferability. We
Adversarially Robust Models may not Transfer Better: Domain Transferability from the View of Regularization

**Figure 4.** Relationship between robustness and transferability when we regularize the feature extractor with Jacobian Regularization (JR) and weight decay (WD).

**Figure 5.** Relationship between robustness and transferability when we use Gaussian noise (Gauss) and posterize (Pos) as data augmentations.

emphasize that our goal is to identify conditions for domain transferability, rather than proposing methods to achieve the state-of-the-art transferable models. Nevertheless, we do show in Appendix D.2 that with basic regularization the model can achieve better absolute transferability than vanilla trained or adversarially trained models in some cases.

**Controlling the last-layer norm.** As shown in our theory, (relative) domain transferability is related to the regularization of feature extractors. Here we regularize the transferability by controlling the last-layer norm $g_s$. Intuitively, when we force the norm of $g_s$ to be big during training, the corresponding norm of $f$ will be regularized to be small.

We use two approaches to control the last-layer norm:

- **Last-layer regularization (LLR):** we impose a strong l2-regularizer with parameter $\lambda_l$ specifically on the weight of $g_s$ and therefore our training loss becomes:
  
  $L_{LLR}(h_s, x, y) = L_{CE}(h_s, x, y) + \lambda_l \cdot ||g_s||_F,$
  
  where $||g_s||_F$ is the frobenius norm of the weight matrix of $g_s$.

- **Last-layer orthogonal training (LLOT):** we directly control the l2-norm of $g_s$ with orthogonal training (Huang et al., 2020)). The orthogonal training will enforce the weight to become a 1-norm matrix and we multiply a constant to obtain the desired norm $||g_s||_2$.

The result of LLR and LLOT are shown in Figure 3. We observe that when we regularize the norm of the last layer to be large (i.e. smaller $\lambda$ in LLR and larger $||g_s||_2$ in LLOT), the relative domain transferability will increase while the model robustness will decrease (their negative correlation is significant with Pearson’s coefficient around $-0.9$). This is because the larger last layer norm will produce a feature extractor $f$ with a smaller norm, which, according to our analysis, leads to a better relative domain transferability. On the other hand, the model $g_s \circ f$ will have a larger norm and therefore becomes less robust under adversarial attacks.

**Controlling the norm of feature extractor.** We directly regularize the feature extractor $f$ and check the impact on the (relative) domain transferability. We implement two regularization as follows:

- **Jacobian regularization (JR):** we follow the approach in (Hoffman et al., 2019) to apply JR on the feature extractor. Given model $h_s = g_s \circ f$, the training loss becomes:
  
  $L_{JR}(g_s \circ f, x, y) = L_{CE}(g_s \circ f, x, y) + \lambda_J \cdot \|J(f, x)\|_F^2,$
  
  where $J(f, x)$ denotes the Jacobian matrix of $f$ on $x$ and $\|\cdot\|_F$ is the frobenius norm.

- **Weight Decay (WD):** we impose weight decay with factor $\lambda_w$ on the feature extractor $f$ during training. This is equivalent to imposing l2-regularizer with factor $\lambda_w$ on the feature extractor (excluding the last layer).

The results under JR and WD are shown in Figure 4. We observe that with larger regularization on the feature extractor, the model shows higher relative domain transferability, which matches our analysis. Meanwhile, the robustness decreases significantly with a large regularizer. This is because a large regularization will harm the model performance on the source domain and lead to low model robustness.

**Noise-dependent data augmentation.** As shown in Section 3, certain data augmentation can be viewed as a type of regularization during training and thus affects the (relative) domain transferability. Here we consider both noise
dependent and independent data augmentations. For the noise-dependent case, We include two augmentations:

- Gaussian Noise data augmentation (Gauss): we add zero-mean Gaussian noise with variance \( \sigma^2 \) to the input image.
- Posterize (Pos): we truncate each channel of one pixel value into \( b \) bits (originally they are 8 bits).

The results of Gauss and Pos are shown in Figure 5. We observe that the relative domain transferability of the trained models improves with greater data augmentation, matching our theory. The robustness also benefits from a small data augmentation but decreases when it becomes large.

Resolution-related (noise-independent) data augmentation. Specifically, for ImageNet to CIFAR-10 transferability, we consider two resolution-related data augmentations. The intuition is that when the target domain has a lower resolution than the source domain (ImageNet is \( 224 \times 224 \) while CIFAR-10 is \( 32 \times 32 \)), the data augmentations that down-sample the inputs during the training on the source domain will help transferability. We consider the below resolution-related augmentations:

- Rescale: we rescale the input to be \( m \) times smaller (i.e., shape ImageNet as \( (224/m) \times (224/m) \)) and then rescale them back to the original size.
- Blur: we apply Gaussian blurring with kernel size \( k \) on the input. The Gaussian kernel is created with a standard deviation randomly sampled from \([0.1, 2.0]\).

The corresponding results are shown in Figure 6. The experiments are evaluated only for ImageNet to CIFAR-10, and we include the results of both ResNet18 (the default model) and WideResNet50. We can see that the data augmentations help with relative domain transferability to the target domain, although the robustness on the source domain decreases since these augmentations do not relate to robustness operations.

4.3. Other Data Augmentations

In addition, we study rotation and translation, the two data augmentations that violate the sufficient condition for regularization as we discussed in Section 3. The result is shown in Figure 7. We observe that these augmentations do not have an obvious impact on domain transferability, which is consistent with our theoretical analysis.

5. Conclusions

In this work, we theoretically analyze the sufficient conditions for (relative) domain transferability based on the view of function class regularization. We also conduct experiments to verify our claims and observe some counterexamples that show negative correlations between robustness and domain transferability. These results would contribute to a better understanding of the domain generalization.

Appendix

A. Proofs

Proposition A.1 (Proposition 2.1 Restated). Given the problem defined in subsection 2.1, \( f_c^{D_S} \) is a minimizer of equation 2. Moreover, if \( c \geq c' \geq 0 \), then the relative domain transfer loss \( \ell_{D_T}(f_c^{D_S}) - \ell_{D_S}(f_c^{D_S}) \geq \ell_{D'_T}(f_c^{D'_S}) - \ell_{D'_S}(f_c^{D'_S}) \).

Proof. Recall that \( \ell_{D_S}(f) = \|f - y_S\|_D, \ell_{D_T}(f) = \|f - y_T\|_D \) and \( f_c^{D_S} := y_S \min \{1, \frac{c}{\|y_S\|_D} \} \). First, let’s verify that

\[
f_c^{D_S} \in \arg \min_{f \in \mathcal{F}} \ell_{D_S}(f), \quad \text{s.t.} \quad \|f\|_D \leq c.
\]

If \( c \geq \|y_S\|_D \), then \( f_c^{D_S} = y_S \) minimizes \( \ell_{D_S}(f) = \|f - y_S\|_D \) to achieve 0.

If \( c < \|y_S\|_D \), then we can show that \( f_c^{D_S} = \frac{c}{\|y_S\|_D} y_S \) achieves the minimum. For any \( f \in \mathcal{F} : \|f\|_D \leq c \), we have

\[
\ell_{D_S}(f) = \|f - y_S\|_D \geq \|y_S\|_D - \|f\|_D \geq \|y_S\|_D - c = \|(1 - \frac{c}{\|y_S\|_D})y_S\|_D = \|y_S - \frac{c}{\|y_S\|_D} y_S\|_D = \ell_{D_S}(f_c^{D_S}).
\]

Therefore, \( f_c^{D_S} \) indeed achieves the minimum.

Now, let’s prove the proposition. For any \( c \geq \|y_S\|_D \), we have \( \ell_{D_S}(f_c^{D_S}) = 0 \) and \( \ell_{D'_T}(f_c^{D'_S}) \) is a constant. Therefore, there is no difference for all \( c \geq \|y_S\|_D \), and the proposition holds for \( c \geq c' \geq \|y_S\|_D \). Then, we only need to verify the case for \( \|y_S\|_D \geq c \geq c' \):

\[
\ell_{D_S}(f_c^{D_S}) - \ell_{D_S}(f_c^{D'_S}) = c - c' = \|\frac{c}{\|y_S\|_D} y_S - \frac{c'}{\|y_S\|_D} y_S\|_D
\]

\[
= \|f_c^{D_S} - f_c^{D'_S}\|_D = \|f_c^{D_S} - y_T + y_T - f_c^{D'_S}\|_D
\]

\[
\geq \|f_c^{D_S} - y_T\|_D - \|y_T - f_c^{D'_S}\|_D
\]

\[
\geq \|f_c^{D_S} - y_T\|_D - \|y_T - f_c^{D'_S}\|_D
\]

\[
= \ell_{D_T}(f_c^{D_S}) - \ell_{D_T}(f_c^{D'_S}).
\]

Rearranging the above inequality gives the proposition. \( \square \)

Proposition A.2 (Proposition 2.4 Restated). \( d_{\mathcal{G}, \mathcal{F}}(\cdot, \cdot) : \mathcal{P}_{X \times Y} \times \mathcal{P}_{X \times Y} \to \mathbb{R}_+ \) satisfies the following three properties.

1. (Symmetry) \( d_{\mathcal{G}, \mathcal{F}}(D_S, D_T) = d_{\mathcal{G}, \mathcal{F}}(D_T, D_S) \).

2. (Triangle Inequality) For \( \forall D' \in \mathcal{P}_{X \times Y} \): \( d_{\mathcal{G}, \mathcal{F}}(D_S, D_T) \leq d_{\mathcal{G}, \mathcal{F}}(D_S, D') + d_{\mathcal{G}, \mathcal{F}}(D', D_T) \).

3. (Weak Zero Property) For \( \forall D \in \mathcal{P}_{X \times Y} \): \( d_{\mathcal{G}, \mathcal{F}}(D, D) = 0 \).

Proof. Recall that

\[
d_{\mathcal{G}, \mathcal{F}}(D_S, D_T) := \sup_{f \in \mathcal{F}} \inf_{g \in \mathcal{G}} \ell_{D_S}(g \circ f) - \inf_{g \in \mathcal{G}} \ell_{D_T}(g \circ f).
\]

We can see that the symmetry and weak zero property are obvious. For triangle inequality, given \( \forall D' \in \mathcal{P}_{X \times Y} \):

\[
d_{\mathcal{G}, \mathcal{F}}(D_S, D_T) = \sup_{f \in \mathcal{F}} \inf_{g \in \mathcal{G}} \ell_{D_S}(g \circ f) - \inf_{g \in \mathcal{G}} \ell_{D_T}(g \circ f)
\]

\[
= \sup_{f \in \mathcal{F}} \inf_{g \in \mathcal{G}} \ell_{D_S}(g \circ f) - \inf_{g \in \mathcal{G}} \ell_{D_T}(g \circ f) + \inf_{g \in \mathcal{G}} \ell_{D_T}(g \circ f) - \inf_{g \in \mathcal{G}} \ell_{D_T}(g \circ f)
\]

\[
\leq \sup_{f \in \mathcal{F}} (\inf_{g \in \mathcal{G}} \ell_{D_S}(g \circ f) - \inf_{g \in \mathcal{G}} \ell_{D'_T}(g \circ f)) + \sup_{f \in \mathcal{F}} (\inf_{g \in \mathcal{G}} \ell_{D_T}(g \circ f) - \inf_{g \in \mathcal{G}} \ell_{D_T}(g \circ f))
\]

\[
\leq \sup_{f \in \mathcal{F}} \ell_{D_S}(g \circ f) - \inf_{g \in \mathcal{G}} \ell_{D_T}(g \circ f) + \sup_{f \in \mathcal{F}} \ell_{D'_T}(g \circ f) - \inf_{g \in \mathcal{G}} \ell_{D_T}(g \circ f)
\]

\[
= d_{\mathcal{G}, \mathcal{F}}(D_S, D') + d_{\mathcal{G}, \mathcal{F}}(D', D_T).
\]

\( \square \)
Proposition A.3. Denote the function class

\[ \mathcal{L}_{g,f} := \{ h_{g,f} : X \times Y \to \mathbb{R} \mid g \in \mathcal{G}, f \in \mathcal{F} \}, \]

where \( h_{g,f}(x, y) := \ell(g \circ f(x), y) \).

Let \( d : X \times Y \to \mathbb{R}_+ \) be a metric on \( X \times Y \), and assume \( \forall h \in \mathcal{L}_{g,f} \) is L-Lipschitz continuous with respect to the metric \( d \).

Then, we have

\[ d_{\mathcal{F}_A}(\mathcal{D}_S, \mathcal{D}_T) \leq L \cdot W(\mathcal{D}_S, \mathcal{D}_T), \]

where \( W(\mathcal{D}_S, \mathcal{D}_T) \) is the Wasserstein distance:

\[ W(\mathcal{D}_S, \mathcal{D}_T) = \sup_{\phi : X \times Y \to \mathbb{R}} \mathbb{E}_{(x,y) \sim \mathcal{D}_S}[\phi(x, y)] - \mathbb{E}_{(x,y) \sim \mathcal{D}_T}[\phi(x, y)] \quad \text{s.t. } \phi \text{ is 1-Lipschitz}. \]

Proof. Recall that

\[ d_{g,f}(\mathcal{D}_S, \mathcal{D}_T) := \sup_{f \in \mathcal{F}} | \inf_{g \in \mathcal{G}} \ell_{\mathcal{D}_S}(g \circ f) - \inf_{g \in \mathcal{G}} \ell_{\mathcal{D}_T}(g \circ f) |. \]

By the definition of \( \inf \), for \( \forall \epsilon > 0 \) there exist \( g_{S,\epsilon}, g_{T,\epsilon} \in \mathcal{G} \) such that

\[ \inf_{g \in \mathcal{G}} \ell_{\mathcal{D}_S}(g \circ f_{\epsilon}) \geq \ell_{\mathcal{D}_S}(g_{S,\epsilon} \circ f_{\epsilon}) - \epsilon \]

\[ \inf_{g \in \mathcal{G}} \ell_{\mathcal{D}_T}(g \circ f_{\epsilon}) \geq \ell_{\mathcal{D}_T}(g_{T,\epsilon} \circ f_{\epsilon}) - \epsilon. \]

By the definition of \( \sup \), there exists \( f_{\epsilon} \in \mathcal{F} \) such that

\[ d_{g,f}(\mathcal{D}_S, \mathcal{D}_T) \leq | \inf_{g \in \mathcal{G}} \ell_{\mathcal{D}_S}(g \circ f_{\epsilon}) - \inf_{g \in \mathcal{G}} \ell_{\mathcal{D}_T}(g \circ f_{\epsilon}) | + \epsilon \]

\[ = \max \{ \inf_{g \in \mathcal{G}} \ell_{\mathcal{D}_S}(g \circ f_{\epsilon}) - \inf_{g \in \mathcal{G}} \ell_{\mathcal{D}_T}(g \circ f_{\epsilon}), \inf_{g \in \mathcal{G}} \ell_{\mathcal{D}_T}(g \circ f_{\epsilon}) - \inf_{g \in \mathcal{G}} \ell_{\mathcal{D}_S}(g \circ f_{\epsilon}) \} + \epsilon \]

\[ \leq \max \{ \ell_{\mathcal{D}_S}(g_{T,\epsilon} \circ f_{\epsilon}) - \ell_{\mathcal{D}_T}(g_{T,\epsilon} \circ f_{\epsilon}), \ell_{\mathcal{D}_T}(g_{S,\epsilon} \circ f_{\epsilon}) - \ell_{\mathcal{D}_S}(g_{S,\epsilon} \circ f_{\epsilon}) \} + 2\epsilon. \]

Let’s first consider the first term in the \( \max \{ \cdot, \cdot \} \) above.

\[ \ell_{\mathcal{D}_S}(g_{T,\epsilon} \circ f_{\epsilon}) - \ell_{\mathcal{D}_T}(g_{T,\epsilon} \circ f_{\epsilon}) \]

\[ = L \cdot \frac{1}{L} \ell_{\mathcal{D}_S}(g_{T,\epsilon} \circ f_{\epsilon}) - \frac{1}{L} \ell_{\mathcal{D}_T}(g_{T,\epsilon} \circ f_{\epsilon}) \]

\[ = L \cdot (\mathbb{E}_{(x,y) \sim \mathcal{D}_S}[\frac{1}{T} \ell((g_{T,\epsilon} \circ f_{\epsilon})(x), y)] - \mathbb{E}_{(x,y) \sim \mathcal{D}_T}[\frac{1}{T} \ell((g_{T,\epsilon} \circ f_{\epsilon})(x), y)]) \]

\[ \leq L \cdot W(\mathcal{D}_S, \mathcal{D}_T), \]

where the inequality is due to that both \( \frac{1}{T} \ell((g_{S,\epsilon} \circ f_{\epsilon})(x), y) \) and \( \frac{1}{T} \ell((g_{T,\epsilon} \circ f_{\epsilon})(x), y) \) are 1-Lipschitz w.r.t. \( (x, y) \) and the metric \( d \).

Similarly, we also have

\[ \ell_{\mathcal{D}_T}(g_{S,\epsilon} \circ f_{\epsilon}) - \ell_{\mathcal{D}_S}(g_{S,\epsilon} \circ f_{\epsilon}) \leq L \cdot W(\mathcal{D}_S, \mathcal{D}_T). \]

Therefore, equation 3 implies

\[ d_{g,f}(\mathcal{D}_S, \mathcal{D}_T) \leq L \cdot W(\mathcal{D}_S, \mathcal{D}_T) + 2\epsilon. \]

Letting \( \epsilon \to 0 \) completes the proof.

Proposition A.4. Consider multi-class classification where \( \mathcal{Y} = [k] \) for some \( k \geq 2 \). Define the loss function \( \ell \) as

\[ \ell(g \circ f(x), y) = 1 \{ \arg \max_{j \in [k]} (g \circ f(x))_j \neq y \} \]

Let \( \delta_{TV}(\mathcal{D}_S, \mathcal{D}_T) \) denote the total variation distance. Then we have

\[ d_{\mathcal{F}_A}(\mathcal{D}_S, \mathcal{D}_T) \leq \delta_{TV}(\mathcal{D}_S, \mathcal{D}_T). \]
Theorem A.5 (Theorem 2.5 Restated)

To prove Theorem 2.6, we first prove the following interesting lemma.

Proof. Fix \( f \in \mathcal{F} \). By the definition of inf, there exists \( g_{T,\epsilon} \) such that

\[
\begin{align*}
| \inf_{g \in \mathcal{G}} \ell_{D_S}(g \circ f) - \inf_{g \in \mathcal{G}} \ell_{D_T}(g \circ f) | \\
\leq | \inf_{g \in \mathcal{G}} \ell_{D_S}(g \circ f) - \ell_{D_T}(g_{T,\epsilon} \circ f) | + \epsilon \\
\leq | \ell_{D_S}(g_{T,\epsilon} \circ f) - \ell_{D_T}(g_{T,\epsilon} \circ f) | + \epsilon \\
= | \mathbb{E}_{(x,y) \sim D_S}[\ell(g_{T,\epsilon} \circ f(x), y)] - \mathbb{E}_{(x,y) \sim D_T}[\ell(g_{T,\epsilon} \circ f(x), y)] | + \epsilon \\
= | \mathbb{P}_{(x,y) \sim D_S}[\mathbb{I}\{\arg\max_{j \in [k]} (g_{T,\epsilon} \circ f)(x)_j \neq y\}] - \mathbb{P}_{(x,y) \sim D_T}[\mathbb{I}\{\arg\max_{j \in [k]} (g_{T,\epsilon} \circ f)(x)_j \neq y\}] | + \epsilon \\
(4)
\end{align*}
\]

Let \( A \) be the event such that \( A = \{(x, y) : \arg\max_{j \in [k]} (g_{T,\epsilon} \circ f)(x)_j \neq y\} \). Then we can write equation 4 as

\[
\begin{align*}
(4) &= | \mathbb{P}_{(x,y) \sim D_S}[A] - \mathbb{P}_{(x,y) \sim D_T}[A] | + \epsilon \\
&\leq \sup_B | \mathbb{P}_{(x,y) \sim D_S}[B] - \mathbb{P}_{(x,y) \sim D_T}[B] | + \epsilon \\
&= \delta_{TV}(D_S, D_T) + \epsilon
\end{align*}
\]

Send \( \epsilon \rightarrow 0 \). Noting that \( f \in \mathcal{F} \) was arbitrary, apply sup to both sides gives us the desired inequality. \( \square \)

Theorem 2.5 can be proved easily by definition.

**Theorem A.5 (Theorem 2.5 Restated).** Given a training algorithm \( A \), for all \( D_S, D_T \in \mathcal{P}_{X \times Y} \) we have

\[
\tau(A; D_S, D_T) \leq d_{\mathcal{F}_A}(D_S, D_T),
\]

or equivalently,

\[
\inf_{x \in \mathcal{V}} \ell_{D_T}(g \circ f^{D_S}_A) \leq \ell_{D_S}(g^{D_S}_A \circ f^{D_S}_A) + d_{\mathcal{F}_A}(D_S, D_T).
\]

Proof. By definition,

\[
\tau(A; D_S, D_T) = \inf_{g \in \mathcal{G}} \ell_{D_T}(g \circ f^{D_S}_A) - \ell_{D_S}(g^{D_S}_A \circ f^{D_S}_A) \\
\leq \inf_{g \in \mathcal{G}} \ell_{D_T}(g \circ f^{D_S}_A) - \inf_{g \in \mathcal{G}} \ell_{D_S}(g \circ f^{D_S}_A) \\
\leq | \inf_{g \in \mathcal{G}} \ell_{D_T}(g \circ f^{D_S}_A) - \inf_{g \in \mathcal{G}} \ell_{D_S}(g \circ f^{D_S}_A) | \\
\leq \sup_{f \in \mathcal{F}_A} | \inf_{g \in \mathcal{G}} \ell_{D_T}(g \circ f) - \inf_{g \in \mathcal{G}} \ell_{D_S}(g \circ f) | \\
= d_{\mathcal{F}_A}(D_S, D_T). \\
\]

\( \square \)

To prove Theorem 2.6, we first prove the following interesting lemma.

**Lemma A.6.** Let \( S_{t}^{d-1} := \{ y \in \mathbb{R}^d \mid \|y\|_2 = r \} \) denotes the \( (d - 1) \)-dimensional sphere in \( \mathbb{R}^d \) with radius \( r > 0 \). If a function \( h : S_{t}^{d-1} \rightarrow \mathbb{R}^d \) satisfies

\[
\forall y \in S_{t}^{d-1} : \quad \langle h(y), y \rangle < 0,
\]

then we have

\[
\tilde{0} \in \text{conv}(h(S_{t}^{d-1})),
\]

i.e., \( \tilde{0} \) is in the convex hull of \( \{h(y) \mid y \in S_{t}^{d-1}\} \).
We assume some properties of the sample individual loss function \( \ell \). We first prove a generalized version of Theorem 2.6 as shown below, and then we can see that Theorem 2.6 is exactly the following theorem but with \( \epsilon = 0 \).

**Theorem A.7 (Generalized Version of Theorem 2.6).** Given any source distribution \( D_S \in \mathcal{P}_{X \times \mathbb{R}^d} \), any fine-tuning function class \( \mathcal{G} \) where \( \mathcal{G} \) includes the zero function, and any training algorithm \( A \), denote

\[
\epsilon := \ell_{D_S}(g_A^{D_S} \circ f_A^{D_S}) - \inf_{g \in \mathcal{G}, f \in F_A} \ell_{D_S}(g \circ f).
\]

We assume some properties of the sample individual loss function \( \ell : \mathbb{R}^d \times \mathbb{R}^d \to \mathbb{R}_+ \): it is differentiable and strictly convex w.r.t. its first argument; \( \ell(y, y) = 0 \) for any \( y \in \mathbb{R}^d \); and \( \lim_{r \to \infty} \inf_{y: \|y\|_2 = r} \ell(\bar{0}, y) = \infty \). Then, for any distribution \( D^X \) on \( X \), there exist some distributions \( D_T \in \mathcal{P}_{X \times Y} \) with its marginal on \( X \) being \( D^X \) such that

\[
\tau(A; D_S, D_T) \leq d_{F_A}(D_S, D_T) \leq \tau(A; D_S, D_T) + \epsilon.
\]

**Proof.** The \( \tau(A; D_S, D_T) \leq d_{F_A}(D_S, D_T) \) is proved by Theorem 2.5, we only need to prove that there exists some \( D_T \in \mathcal{P}_{X \times Y} \) with its marginal on \( X \) being \( D^X \) such that

\[
d_{F_A}(D_S, D_T) \leq \tau(A; D_S, D_T) + \epsilon = \inf_{g \in \mathcal{G}, f \in F_A} \ell_{D_T}(g \circ f_A^{D_S}) - \inf_{g \in \mathcal{G}, f \in F_A} \ell_{D_S}(g \circ f).
\]

We begin by observing that \( \lim_{r \to \infty} \inf_{y: \|y\|_2 = r} \ell(\bar{0}, y) = \infty \), and thus there exists \( r > 0 \) such that

\[
\forall y \in S^{d-1} : \quad \ell(\bar{0}, y) \geq \ell_{D_S}(\bar{0}) = E_{(x,y) \sim D_S}[\ell(\bar{0}, y)],
\]

where \( S^{d-1} := \{ y \in \mathbb{R}^d \mid \|y\|_2 = r \} \) denotes the \((d-1)\)-dimensional sphere with radius \( r \). Note the we abuse the notion a bit to let \( \bar{0} \) also denotes the zero function (i.e., maps all input to zero). Now, let us define at the following set

\[
\mathcal{V} := \{ \nabla_1 \ell(\bar{0}, y) \mid y \in S^{d-1} \},
\]

where \( \nabla_1 \) is taking the gradient w.r.t. the first argument of \( \ell(\cdot, \cdot) \). By the strict convexity of \( \ell(\cdot, y) \), we have

\[
\ell(y, y) - \ell(\bar{0}, y) > \langle \nabla_1 \ell(\bar{0}, y), y \rangle.
\]

Noting that \( \ell(y, y) = 0 \) is the unique minimum of \( \ell(\cdot, y) \), we have \( \ell(\bar{0}, y) > 0 \). Accordingly,

\[
\forall y \in S^{d-1} : \quad 0 > -\ell(\bar{0}, y) > \langle \nabla_1 \ell(\bar{0}, y), y \rangle.
\]

Having the above property, and noting that \( \nabla_1 \ell(\bar{0}, \cdot) : S^{d-1} \to \mathbb{R}^d \), we can invoke Lemma A.6 to see that

\[
\bar{0} \in \text{conv}(\mathcal{V}).
\]

Therefore, there exists \( n \) points \( \{ y_i \}_{i=1}^n \subset S^{d-1} \) such that

\[
\bar{0} = \sum_{i=1}^n c_i \nabla_1 \ell(\bar{0}, y_i),
\]
where \( c_i > 0 \) and \( \sum_{i=1}^{n} c_i = 1 \).

Therefore, we can define the target distribution \( D_T \) as the following. Given any \( x \sim D^X \), the distribution of \( y \) conditioned on \( x \) is: \( y = y_i \) with probability \( c_i \). Now we verify the distribution \( D_T \) indeed makes the bound \( \epsilon \)-tight. Denote a strictly convex function \( h : \mathbb{R}^d \to \mathbb{R}_+ \) as the following

\[
h(\cdot) := \sum_{i=1}^{n} c_i \ell(\cdot, y_i).
\]

Since \( h \) is strictly convex and \( \nabla h(\tilde{0}) = \tilde{0} \) (equation 8), we can see that \( h(\tilde{0}) \) achieves the unique global minimum of \( h \) on \( \mathbb{R}^d \).

Therefore, given the \( D_T \), for any \( \forall f \in F_A \) we have

\[
\inf_{g \in \mathcal{G}} \ell_{D_T} (g \circ f) = \inf_{g \in \mathcal{G}} \mathbb{E}_{(x,y) \sim D_T} [\ell(g \circ f(x), y)] \\
= \inf_{g \in \mathcal{G}} \mathbb{E}_{x \sim D^X} \left[ \sum_{i=1}^{n} c_i \ell(g \circ f(x), y_i) \right] \\
= \inf_{g \in \mathcal{G}} \mathbb{E}_{x \sim D^X} [h(g \circ f(x))] \\
= h(\tilde{0}) \quad \text{(G contains the zero function)} \\
= \sum_{i=1}^{n} c_i \ell(\tilde{0}, y_i). \tag{9}
\]

Recall that \( d_{F_A}(D_S, D_T) = \sup_{f \in F_A} | \inf_{g \in \mathcal{G}} \ell_{D_T} (g \circ f) - \inf_{g \in \mathcal{G}} \ell_{D_S} (g \circ f) | \), we can see that

\[
d_{F_A}(D_S, D_T) = \sup_{f \in F_A} | \sum_{i=1}^{n} c_i \ell(\tilde{0}, y_i) - \inf_{g \in \mathcal{G}} \ell_{D_S} (g \circ f) | \tag{10}
\]

By equation 7, for \( \forall f \in F_A \), we have

\[
\sum_{i=1}^{n} c_i \ell(\tilde{0}, y_i) \geq \ell_{D_S}(\tilde{0}) = \ell_{D_S}(\tilde{0} \circ f) \geq \inf_{g \in \mathcal{G}} \ell_{D_S} (g \circ f).
\]

Hence, we can continue as

\[
(10) = \sup_{f \in F_A} \left( \sum_{i=1}^{n} c_i \ell(\tilde{0}, y_i) - \inf_{g \in \mathcal{G}} \ell_{D_S} (g \circ f) \right) = \sum_{i=1}^{n} c_i \ell(\tilde{0}, y_i) - \inf_{g \in \mathcal{G}, f \in F_A} \ell_{D_S} (g \circ f) \\
= \inf_{g \in \mathcal{G}} \ell_{D_T} (g \circ f_A^{D_S}) - \inf_{g \in \mathcal{G}, f \in F_A} \ell_{D_S} (g \circ f) \quad \text{(by equation 9)} \\
= \inf_{g \in \mathcal{G}} \ell_{D_T} (g \circ f_A^{D_S} - \ell_{D_S}(g_A^{D_S} \circ f_A^{D_S})) + \ell_{D_S}(g_A^{D_S} \circ f_A^{D_S}) - \inf_{g \in \mathcal{G}, f \in F_A} \ell_{D_S} (g \circ f) \\
= \tau(A; D_S, D_T) + \epsilon.
\]

Therefore, it holds that \( d_{F_A}(D_S, D_T) \leq \tau(A; D_S, D_T) + \epsilon \), and thus the theorem.

\[ \square \]

An alternative form of the tightness bound may be derived from the above theorem, and the alternative forms present the tightness result from a different perspective. Noting that the upper bound in Theorem 2.5 states that the following inequality always hold:

\[
\tau(A; D_S, D_T) - d_{F_A}(D_S, D_T) \leq 0,
\]

The tightness of this upper bound depends on whether we can derive a lower bound for \( \tau(A; D_S, D_T) - d_{F_A}(D_S, D_T) \).
With equation 14, we can prove the lemma as the following. Given \( \forall \)

We show in the following that, under the same settings as Theorem A.7,

\[
\inf_{D_S, D_T} \sup_{\tau \in \Gamma(D^X)} (\tau(A; D_S, D_T) - d_{f_A}(D_S, D_T)) \geq -\epsilon,
\]

where \( \Gamma(D^X) \) denotes the distributions whose marginal distribution on \( X \) is \( D^X \). Theorem A.7 implies that there exists a \( D_T \) whose marginal on \( X \) is \( D^X \) such that \( \tau(A; D_S, D_T) - d_{f_A}(D_S, D_T) \geq -\epsilon \). Therefore, \( \sup_{\tau \in \Gamma(D^X)} (\tau(A; D_S, D_T) - d_{f_A}(D_S, D_T)) \geq -\epsilon \). Then, taking the infimum over all pairs of source distributions and target marginal distribution gives the min-max type of lower bound as shown above. Equation 11 is essentially an equivalent statement as the statement of Theorem A.7, but its perspective may be more clear and more interesting to some of the readers.

**Lemma A.8 (Lemma 2.8 Restated).** Assuming the individual loss function \( \ell : \mathcal{Y} \times \mathcal{Y} \to [0, c] \), given any distribution \( D \in \mathcal{P}_{X \times Y} \) and \( \forall \delta > 0 \), with probability \( \geq 1 - \delta \) we have

\[
d_{g,f}(D, \hat{D}^n) \leq 2 \text{Rad}_{\hat{D}^n}(L_{g,f}) + 3c \sqrt{\frac{\ln(4/\delta)}{2n}}.
\]

**Proof.** Given any \( \delta > 0 \), \( f \in \mathcal{F}, g \in \mathcal{G}, D \in \mathcal{P}_{X \times Y} \), and taking any \( h_{g,f} \in L_{g,f} \) (Definition 2.7), with probability \( \geq 1 - \delta \) we have

\[
\ell_D(g \circ f) - \ell_{\hat{D}^n}(g \circ f) = \mathbb{E}_{(x,y) \sim D}[h_{g,f}(x,y)] - \frac{1}{n} \sum_{i=1}^{n} h_{g,f}(x_i, y_i)
\leq 2 \text{Rad}_{\hat{D}^n}(L_{g,f}) + 3c \sqrt{\frac{\ln(2/\delta)}{2n}},
\]

where the inequality is by the well-known Rademacher complexity uniform bound. Similarly,

\[
\ell_{\hat{D}^n}(g \circ f) - \ell_D(g \circ f) = \mathbb{E}_{(x,y) \sim D}[-h_{g,f}(x,y)] - \frac{1}{n} \sum_{i=1}^{n} -h_{g,f}(x_i, y_i)
\leq 2 \text{Rad}_{\hat{D}^n}(-L_{g,f}) + 3c \sqrt{\frac{\ln(2/\delta)}{2n}}
\]

\[
= 2 \text{Rad}_{\hat{D}^n}(L_{g,f}) + 3c \sqrt{\frac{\ln(2/\delta)}{2n}}.
\]

The probability that both events equation 12 and equation 13 happen can be upper bounded by union bound, i.e.,

\[
\Pr((12) \land (13)) = 1 - \Pr((12)^c \lor (13)^c) \geq 1 - \left( \Pr((12)^c) + \Pr((13)^c) \right) \geq 1 - 2\delta.
\]

Therefore, combining the above with probability \( \geq 1 - \delta \) we have

\[
|\ell_D(g \circ f) - \ell_{\hat{D}^n}(g \circ f)| \leq 2 \text{Rad}_{\hat{D}^n}(L_{g,f}) + 3c \sqrt{\frac{\ln(4/\delta)}{2n}}.
\]

With equation 14, we can prove the lemma as the following. Given \( \forall \epsilon > 0 \), by the definition of infimum there exists a \( g_\epsilon \in \mathcal{G} \) such that

\[
\ell_D(g_\epsilon \circ f) < \inf_{g \in \mathcal{G}} \ell_D(g \circ f) + \epsilon.
\]

By equation 14, with probability \( \geq 1 - \delta \) we have

\[
\ell_{\hat{D}^n}(g_\epsilon \circ f) \leq \ell_D(g_\epsilon \circ f) + 2 \text{Rad}_{\hat{D}^n}(L_{g,f}) + 3c \sqrt{\frac{\ln(4/\delta)}{2n}}.
\]

Moreover, by definition

\[
\inf_{g \in \mathcal{G}} \ell_{\hat{D}^n}(g \circ f) \leq \ell_{\hat{D}^n}(g_\epsilon \circ f).
\]
Combining the above three inequalities we have

$$\inf_{g \in G} \ell_{\hat{D}^n}(g \circ f) < \inf_{g \in G} \ell_D(g \circ f) + \epsilon + 2\text{Rad}_{\hat{D}^n}(L_{\mathcal{G},F}) + 3c\sqrt{\frac{\ln(4/\delta)}{2n}}.$$ 

Letting $\epsilon \to 0$, we can see that

$$\inf_{g \in G} \ell_{\hat{D}^n}(g \circ f) \leq \inf_{g \in G} \ell_D(g \circ f) + 2\text{Rad}_{\hat{D}^n}(L_{\mathcal{G},F}) + 3c\sqrt{\frac{\ln(4/\delta)}{2n}}.$$ 

Similarly, we can derive the above inequality again but with $D$ and $\hat{D}^n$ switched. Therefore,

$$|\inf_{g \in G} \ell_{\hat{D}^n}(g \circ f) - \inf_{g \in G} \ell_D(g \circ f)| \leq 2\text{Rad}_{\hat{D}^n}(L_{\mathcal{G},F}) + 3c\sqrt{\frac{\ln(4/\delta)}{2n}}.$$ 

Since the above inequality holds for $\forall f \in \mathcal{F}$, taking the supremum over $f \in \mathcal{F}$ gives the lemma.

**Lemma A.9.** Assuming the individual loss function $\ell : \mathcal{Y} \times \mathcal{Y} \to [0,c]$, given any distributions $D_S, D_T \in \mathcal{P}_{X \times Y}$ and $\forall \delta > 0$, with probability $\geq 1 - \delta$ we have

$$d_{\mathcal{F}_A}(D_S, D_T) \leq d_{\mathcal{F}_A}(\hat{D}_S^n, \hat{D}_T^n) + 2(\text{Rad}_{\hat{D}_S^n}(L_{\mathcal{G},F_A}) + \text{Rad}_{\hat{D}_T^n}(L_{\mathcal{G},F_A})) + 6c\sqrt{\frac{\ln(8/\delta)}{2n}}.$$ 

**Proof.** By Proposition 2.4, we apply the triangle inequality to derive

$$d_{\mathcal{F}_A}(D_S, D_T) \leq d_{\mathcal{F}_A}(D_S, \hat{D}_T^n) + d_{\mathcal{F}_A}(\hat{D}_T^n, D_T) \leq d_{\mathcal{F}_A}(D_S, \hat{D}_T^n) + d_{\mathcal{F}_A}(\hat{D}_T^n, D_T) + d_{\mathcal{F}_A}(\hat{D}_S^n, D_S).$$ 

By Lemma 2.8, we can apply the union bound argument (e.g., see the proof of Lemma 2.8) to bound $d_{\mathcal{F}_A}(\hat{D}_T^n, D_T)$ and $d_{\mathcal{F}_A}(\hat{D}_S^n, D_S)$. That being said, $\forall \delta' > 0$ with probability $\geq 1 - 2\delta'$ we have

$$d_{\mathcal{F}_A}(\hat{D}_T^n, D_T) \leq 2\text{Rad}_{\hat{D}_T^n}(L_{\mathcal{G},F_A}) + 3c\sqrt{\frac{\ln(4/\delta')} {2n}}.$$ 

$$d_{\mathcal{F}_A}(\hat{D}_S^n, D_S) \leq 2\text{Rad}_{\hat{D}_S^n}(L_{\mathcal{G},F_A}) + 3c\sqrt{\frac{\ln(4/\delta')} {2n}}.$$ 

Therefore,

$$d_{\mathcal{F}_A}(\hat{D}_T^n, D_T) + d_{\mathcal{F}_A}(\hat{D}_S^n, D_S) \leq 2(\text{Rad}_{\hat{D}_S^n}(L_{\mathcal{G},F_A}) + \text{Rad}_{\hat{D}_T^n}(L_{\mathcal{G},F_A})) + 6c\sqrt{\frac{\ln(8/\delta')} {2n}}.$$ 

Denoting $\delta = 2\delta'$ gives the lemma.

**Theorem A.10** (Theorem 2.9 Restated). Given $\forall D_S, D_T \in \mathcal{P}_{X \times Y}$, for $\forall \delta > 0$ with probability $\geq 1 - \delta$ we have

$$\tau(A; \hat{D}_S^n, D_T) \leq d_{\mathcal{F}_A}(\hat{D}_S^n, \hat{D}_T^n) + 2\text{Rad}_{\hat{D}_T^n}(L_{\mathcal{G},F_A}) + 4\text{Rad}_{\hat{D}_S^n}(L_{\mathcal{G},F_A}) + 9c\sqrt{\frac{\ln(8/\delta)}{2n}}.$$ 

**Proof.** For $\forall \delta > 0$, from the proof of Lemma A.9 we can see that with probability $\geq 1 - \delta$:

$$d_{\mathcal{F}_A}(\hat{D}_S^n, D_S) \leq 2\text{Rad}_{\hat{D}_S^n}(L_{\mathcal{G},F_A}) + 3c\sqrt{\frac{\ln(8/\delta)}{2n}}.$$ 

$$d_{\mathcal{F}_A}(\hat{D}_T^n, D_T) \leq 2\text{Rad}_{\hat{D}_T^n}(L_{\mathcal{G},F_A}) + 3c\sqrt{\frac{\ln(8/\delta)}{2n}}.$$
and Lemma A.9 holds. Therefore

\[\tau(A; \hat{D}_n^S, D_T) = \inf_{g \in G} \ell_{D_T}(g \circ f_{A}^S) - \ell_{\hat{D}_n^S}(g_{A}^S \circ f_{A}^S)\]

\[\leq \inf_{g \in G} \ell_{D_T}(g \circ f_{A}^S) - \inf_{g \in G} \ell_{\hat{D}_n^S}(g \circ f_{A}^S)\]

\[= \inf_{g \in G} \ell_{D_T}(g \circ f_{A}^S) - \inf_{g \in G} \ell_{D_S}(g \circ f_{A}^S) + \inf_{g \in G} \ell_{D_S}(g \circ f_{A}^S) - \inf_{g \in G} \ell_{\hat{D}_n^S}(g \circ f_{A}^S)\]

\[\leq d_{\mathcal{F}_A}(D_S, D_T) + d_{\mathcal{F}_A}(\hat{D}_n^S, D_S)\]

\[\leq d_{\mathcal{F}_A}(D_S, D_T) + 2\text{Rad}_{\hat{D}_n^S}(\mathcal{L}_{G}, x_A) + 3c\sqrt{\frac{\ln(8/\delta)}{2n}}\]

\[\leq d_{\mathcal{F}_A}(\hat{D}_n^S, D_T) + 2\text{Rad}_{\hat{D}_n^S}(\mathcal{L}_{G}, x_A) + 4\text{Rad}_{\hat{D}_n^S}(\mathcal{L}_{G}, x_A) + 9c\sqrt{\frac{\ln(8/\delta)}{2n}},\]

where the first inequality is by definition of infimum, the second inequality is by the Definition 2.3, the third inequality is by equation 15 and the last inequality is by Lemma A.9.

\[\square\]

**B. Data augmentation (DA) as Regularization**

In this section, we discuss data augmentation (DA) as a concrete example of regularization for training feature extractor \(f_{A}^S\), and explore its impact on the function class \(\mathcal{F}_A\) discussed in Section 2.

Empirical research has shown evidence of the regularization effect of DA (Hernández-García & König, 2018a;b). However, there is a lack of theoretical analysis, and thus we aim to construct a theoretical framework to understand under what sufficient conditions DA can be viewed as regularization on the feature extractor function class \(\mathcal{F}_A\). We categorize DA into *feature-level DA* and *data-level DA*, and for each category, we analyze different DA algorithms to characterize the sufficient conditions under which DA regularizes the function class \(\mathcal{F}_A\). Combined with analysis in Theorem 2.9, we also provide concrete sufficient conditions to tighten the upper bound of relative transferability \(\tau(A; \hat{D}_n^S, D_T)\).

**General Settings.** For the following discussion we apply a general DA setting of affine transformation (Perez & Wang, 2017), taking the form of \(x_\ast = W_\ast^T x + b_\ast\), where \((x, x_\ast)\) is a pair of the original and augmented samples, \((W_\ast, b_\ast)\) are parameters representing specific DA policies. We set \(g : \mathbb{R}^d \rightarrow \mathbb{R}\) as the linear layer corresponding to the weight matrix \(W_\ast\), which will be composed with the feature extractor \(f : \mathbb{R}^m \rightarrow \mathbb{R}^d\). We use squared loss for \(\ell : \mathbb{R} \times \mathbb{R} \rightarrow \mathbb{R}\), and let \(\ell_{\mathcal{F}_A}(g \circ f)\) be the objective function given by training algorithm \(A\) from Theorem 2.9.

**B.1. Feature-level DA (A\(^{FL}\))**

Feature-level DA (Wong et al., 2016; DeVries & Taylor, 2017) requires the transformation to be performed in the learned feature space, which gives us an augmented feature \(W_\ast f(x) + b_\ast\). We use Loss-Averaging algorithm where we take an average of the loss over augmented features for training. Denote the training algorithm based on feature-level DA as \(A^{FL}\), the objective function is as below.

\[\ell_{\mathcal{F}_A^{FL}}(g \circ f) = \frac{1}{n} \sum_{i=1}^{n} \mathbb{E}_{W, b, \mathcal{L}} \ell\left(g \circ (W_\ast f(x_i) + b_\ast), y_i\right)\]

**Theorem B.1.** Apply feature-level DA with affine transformation parameters \((W_\ast, b_\ast)\) s.t. 1) \(\mathbb{E}_{W_\ast}[W_\ast] = \mathbb{I}_m\); 2) \(W_\ast \neq \mathbb{I}_m\) (i.e., \(W_\ast\) is not an identity matrix); 3) \(\mathbb{E}_{W_\ast}[b_\ast] = \mathbb{0}_m\); 4) \(W_\ast\) and \(b_\ast\) are independent. Set \(\ell : \mathbb{R} \times \mathbb{R} \rightarrow \mathbb{R}\) as squared loss; Define \(\Delta_{W_\ast} := W_\ast - \mathbb{I}_m\), then we have

\[\ell_{\mathcal{F}_A^{FL}}(g \circ f) = \ell_{\mathcal{F}_A}(g \circ f) + \Omega_{A^{FL}},\]

where \(\Omega_{A^{FL}} = \frac{1}{n} \sum_{i=1}^{n} \mathbb{E}_{W_\ast} \left[\|f(x_i)^\top \Delta_{W_\ast} W_\ast\|_2^2\right] + \mathbb{E}_{b_\ast} \left[\|b_\ast^\top W_\ast\|_2^2\right]\).

**Proof.** \(\ell''(W_\ast^T \circ f(x_i)) = 2\) for \(\ell\) as squared loss. Apply Taylor expansion to \(\ell\left(g \circ (W_\ast f(x_i) + b_\ast), y_i\right)\) around \(f(x_i)\), all
higher-than-two order terms will vanish:
\[
\mathbb{E}_{W, \cdot, b_{}} \left[ \ell \left( g \circ (W_{*} f(x_{i}) + b_{*}), y_{i} \right) \right] = \mathbb{E}_{W, \cdot, b_{}} \left[ \ell \left( W^{T}_{g} \circ f(x_{i}), y_{i} \right) + W^{T}_{g} (\Delta W_{*} f(x_{i}) + b_{*}) \ell' (W^{T}_{g} \circ f(x_{i}), y_{i}) + \frac{1}{2} W^{T}_{g} (\Delta W_{*} f(x_{i}) + b_{*}) (\Delta W_{*} f(x_{i}) + b_{*}) ^{T} \ell'' (W^{T}_{g} \circ f(x_{i}), y_{i}) W_{g} \right] = \ell \left( W^{T}_{g} \circ f(x_{i}), y_{i} \right) + \mathbb{E}_{W, \cdot, b_{}} \left[ \left\| W^{T}_{g} (\Delta W_{*} f(x_{i}) + b_{*}) \right\|_{2}^{2} \right] + \mathbb{E}_{b_{*}} \left[ \left\| b_{*}^{T} W_{g} \right\|_{2}^{2} \right] ;
\]

The second equality holds since \( \mathbb{E}_{\Delta W_{*}} = \mathbb{E}_{W} [W_{*} - \mathbb{I}_{m}] = 0 \) and \( \mathbb{E}_{b_{*}} = 0 \); the third equality holds since \( W_{i} \) and \( b_{i} \) are independent. Therefore, \( \ell_{\mathcal{F}^{n}, A^{FL}} (g \circ f) = \frac{1}{n} \sum_{i=1}^{n} \mathbb{E}_{W, \cdot, b_{}} \left[ \ell \left( g \circ (W_{*} f(x_{i}) + b_{*}), y_{i} \right) \right] = \ell_{\mathcal{F}^{n}, A} (g \circ f) + \Omega_{A^{FL}}. \)

**Interpretation.** \( \Omega_{A^{FL}} \) is composed of two segments: 1) \( l_{2} \) regularization to an \( f \)-dependent scalar averaged over \( W_{*} \) and \( x_{i} \); 2) \( l_{2} \) regularization to an \( f \)-independent scalar averaged over \( b_{*} \). Due to the regularization effect on \( f \) from the first segment of \( \Omega_{A^{FL}} \), we can reasonably expect the function class \( \mathcal{F}_{A^{P}} \) enabled by \( A^{P} \) to be a subset of that enabled by a general training algorithm \( A \).

**Sufficient conditions.** Combined with Theorem 2.9, the sufficient conditions to tighten the upper bound \( d_{\mathcal{F}_{A}} (\mathcal{D}_{S}^{n}, \mathcal{D}_{T}^{n}) \) for the relative transferability \( \tau (A; \mathcal{D}_{S}, \mathcal{D}_{T}) \) are: feature-level DA (\( A^{FL} \)) with parameters satisfying: 1) \( \mathbb{E}_{W} [W_{*}] = \mathbb{I}_{m} \); 2) \( W_{*} \neq \mathbb{I}_{m} \); 3) \( \mathbb{E}_{b_{*}} [b_{*}] = 0 \); 4) \( W_{*} \) and \( b_{*} \) are independent.

**B.2. Data-level DA (\( A^{DL} \)).**

Data-level DA requires that the transformation to be performed in the input space to generate augmented samples \( W_{*} x + b_{*} \). We cover analysis on two ubiquitous algorithms for data-level DA training: *Prediction-Averaging (\( A^{DL}_{P} \))* (Lyle et al., 2019) and *Loss-Averaging (\( A^{DL}_{L} \))* (Wong et al., 2016). The difference between \( A^{DL}_{P} \) and \( A^{DL}_{L} \) lies in whether we take the average of the prediction or the losses:
\[
\ell_{\mathcal{F}^{n}, A^{DL}_{P}} (g \circ f) := \frac{1}{n} \sum_{i=1}^{n} \ell \left( \mathbb{E}_{W, \cdot, b_{}} \left[ g \circ f(W_{*} x_{i} + b_{*}) \right], y_{i} \right) ;
\]
\[
\ell_{\mathcal{F}^{n}, A^{DL}_{L}} (g \circ f) := \frac{1}{n} \sum_{i=1}^{n} \mathbb{E}_{W, \cdot, b_{}} \left[ \ell \left( g \circ f(W_{*} x_{i} + b_{*}), y_{i} \right) \right].
\]

**Theorem B.2.** Define the data-level deviation caused by data-level DA \( A^{DL} \in \{ A^{DL}_{P}, A^{DL}_{L} \} \) with parameters \( (W_{*}, b_{*}) \) from the original data sample as \( \Delta x_{i} := (W_{*} - \mathbb{I}_{m}) x_{i} + b_{*} \), and define \( \Delta^{3} : = \mathbb{E}_{x, W_{*}, b_{*}} \left[ \left\| \Delta x_{i} \right\|_{2}^{3} \right] \). Suppose we apply data-level DA s.t. 1) \( \mathbb{E}_{W} [W_{*}] = \mathbb{I}_{m} \); 2) \( \mathbb{E}_{b_{*}} [b_{*}] = 0 \); 3) \( \mathcal{O} (\Delta^{3}) \approx 0, \forall j \in \mathbb{N}_{+}, j \geq 3 \); 4) \( W_{*} \) and \( b_{*} \) are independent. Define \( \Delta W_{x} := W_{*} - \mathbb{I}_{m} \in \mathbb{R}^{m \times m}, \Delta^{g}_{i} := W^{T}_{g} f(x_{i}) - y_{i} \in \mathbb{R} \). Let \( W^{(k)}_{g} \in \mathbb{R} \) be the \( k \)-th dimension component of \( W_{g} \) and then define \( w_{i, (k)} := W^{(k)}_{g} \Delta^{g}_{i} \in \mathbb{R} \). Denote the Hessian matrix of the \( k \)-th dimension component in \( f(x_{i}) \) as \( \mathcal{H}^{(k)}_{f} \). Let \( \nabla \) be the Jacobian matrix of \( f \), then we have
\[
\ell_{\mathcal{F}^{n}, A^{DL}} (g \circ f) = \ell_{\mathcal{F}^{n}, A} (g \circ f) + \Omega_{A^{DL}} + \mathcal{O} (\Delta^{3}),
\]
where \( \Omega_{A^{DL}} = \frac{1}{n} \sum_{i=1}^{n} \sum_{k=1}^{d} w_{i, (k)} \left[ \text{tr} \left( \mathbb{E}_{W} [\Delta x_{i} \nabla^{T} f(x_{i}) \mathcal{H}^{(k)}_{f}] \right) \right], \text{where} \Delta x_{i} = (W_{*} - \mathbb{I}) x_{i} + b_{*}; \Omega_{A^{DL}} = \Omega_{A^{DL}_{P}} + \frac{1}{n} \sum_{i=1}^{n} \left[ \mathbb{E}_{W} \left[ x_{i}^{T} \Delta W_{x} \nabla f(x_{i}) W_{g} \right]^{2} + \mathbb{E}_{b_{*}} \left[ b_{*}^{T} \nabla f(x_{i}) W_{g} \right]^{2} \right].
Adversarially Robust Models may not Transfer Better: Domain Transferability from the View of Regularization

Proof. Let $\Delta_{f,A^3_{PL}} := E_{W,b}\{f(W^* x_i + b_*) - f(x_i)\}$, then

$$
\Delta_{f,A^3_{PL}} := E_{W,b}\{f(W^* x_i + b_*) - f(x_i)\}
$$

$$
= E_{W,b}\{\nabla f(x_i)^T (\Delta x_i) + \frac{1}{2} E_{x_i,\Delta x_i} [\Delta x_i^T H_f^{(k),i}(x_i) \Delta x_i]_d + O(E_{W,b}, \|\Delta x_i\|^3_2)\}
$$

$$
- \frac{1}{2} E_{W,b}\{[\Delta x_i^T H_f^{(k),i}(x_i) \Delta x_i]_d + O(E_{W,b}, \|\Delta x_i\|^3_2)\},
$$

(17)

where $[\cdot]_d$ denotes a d-dimensional vector and $k$ denotes the $k$th dimension element. Since $\ell$ is squared loss, the third-and-higher derivative are 0, therefore, the third-and-higher order terms in Taylor expansion to $\ell(E_{W,b}\{g \circ f(W^*x_i + b_*)\}, y_i)$ around $f(x_i)$ will vanish:

$$
\ell(E_{W,b}\{g \circ f(W^*x_i + b_*)\}, y_i)
$$

$$
= \ell(g \circ f(x_i), y_i) + W_g^T (\Delta_{f,A^3_{PL}})^T W_g \ell''(g \circ f(x_i), y_i) + O(E_{W,b}\|\Delta x_i\|^4_2)
$$

(18)

Substitute Eq. (17) into the first-order term in Eq. (18), we have

$$
W_g^T (\Delta_{f,A^3_{PL}})^\ell'(g \circ f(x_i), y_i) = W_g^T E_{W,b}\{[\Delta x_i^T H_f^{(k),i} \Delta x_i]_d \Delta y_i + O(E_{W,b}, \|\Delta x_i\|^3_2)\}
$$

$$
= \Delta y_i \sum_{k=1}^d W_g^{(k)} E_{W,b}\{[\Delta x_i^T H_f^{(k),i} \Delta x_i]_d + O(E_{W,b}, \|\Delta x_i\|^3_2)\}
$$

$$
= \sum_{k=1}^d w_{i,(k)} tr(E_{W,b}\{[\Delta x_i \Delta x_i^T H_f^{(k),i}] + O(E_{W,b}, \|\Delta x_i\|^3_2)\}).
$$

(19)

Substitute Eq. (19) into Eq. (18), we have

$$
\ell(E_{W,b}\{g \circ f(W^*x_i + b_*)\}, y_i) = \ell(g \circ f(x_i), y_i) + \sum_{k=1}^d w_{i,(k)} tr(E_{W,b}\{[\Delta x_i \Delta x_i^T H_f^{(k),i}] + O(E_{W,b}, \|\Delta x_i\|^3_2)\}) + O(E_{W,b}, \|\Delta x_i\|^3_2).
$$

(20)

Substitute Eq. (20) into Eq. (16) which is the definition of $\ell_{\bar{B}^n, A^3_{PL}}(g \circ f)$, and recall that $\Delta_x^3 := E_{x_i,W,b}\{\|\Delta x_i\|^3_2\}$, we have

$$
\ell_{\bar{B}^n, A^3_{PL}}(g \circ f) := \frac{1}{n} \sum_{i=1}^n \ell(E_{W,b}\{g \circ f(W^*x_i + b_*)\}, y_i) = \ell_{\bar{B}^n, A}(g \circ f) + \Omega_{A^3_{PL}} + O(\Delta_x^3).
$$

(21)

Let $\Delta_{f,A^3_{PL}} := f(W^* x_i + b_*) - f(x_i) = \nabla f(x_i)^T (\Delta W^* x + b) + O(\|\Delta x_i\|^3_2)$. Applying Taylor expansion to $E_{W,b}\{\ell(g \circ f(W^*x_i + b_*)\}$ around $f(x_i)$ will give us

$$
E_{W,b}\{\ell(g \circ f(W^*x_i + b_*)\} = \ell(g \circ f(x_i), y_i) + W_g^T E_{W,b}\{[\Delta_{f,A^3_{PL}}] \ell'(g \circ f(x_i), y_i) + \frac{1}{2} W_g^T E_{W,b}\{[\Delta_{f,A^3_{PL}}] \ell'(g \circ f(x_i), y_i) \}
$$

(22)

Since $E_{W,b}\Delta_{f,A^3_{PL}} = \Delta_{f,A^3_{PL}}$, the first-order term in Eq. (22) is exactly Eq. (19):

$$
W_g^T E_{W,b}\{[\Delta_{f,A^3_{PL}}] \ell'(g \circ f(x_i), y_i)
$$

$$
= W_g^T \Delta_{f,A^3_{PL}} \ell'(g \circ f(x_i), y_i)
$$

$$
= \sum_{k=1}^d w_{i,(k)} tr(E_{W,b}\{[\Delta x_i \Delta x_i^T H_f^{(k),i}] + O(E_{W,b}, \|\Delta x_i\|^3_2)\}).
$$

(23)
The second-order term in Eq. (22) is

\[
\frac{1}{2} W_g^T E_{W, b_*} \left[ (\Delta_{f, A^{DL}_g})^T (\Delta_{f, A^{DL}_g}) \right] W_g \ell''(g \circ f(x_i), y_i) \\
= W_g^T E_{W, b_*} \left[ (\nabla f(x_i))^T (\Delta_{f, x_i} + b_*) (\Delta_{f, x_i} + b_*)^T \nabla f(x_i) \right] W_g + \mathcal{O}(E_{W, b_*} \| \Delta_x \|_2^4) \\
= E_{W, x_i} \| x_i^T \Delta_{W_g} \nabla f(x_i) W_g \|^2_2 + E_{b_*} \| b_*^T \nabla f(x_i) W_g \|^2_2 + \mathcal{O}(E_{W, b_*} \| \Delta_x \|_2^4) \tag{24}
\]

Substituting Eq. (23) and Eq. (24) into Eq. (22), we have

\[
E_{W, b_*} \left[ \ell (g \circ f(W_* x_i + b_*), y_i) \right] \\
= \ell (g \circ f(x_i), y_i) + \sum_{k=1}^d w_{i}(k) \text{tr} (E_{W, b_*} \left[ \Delta_{x_i} \Delta_{x_i}^T \right] H_f^{(k)}) + \\
E_{W, x_i} \| x_i^T \Delta_{W_g} \nabla f(x_i) W_g \|^2_2 + E_{b_*} \| b_*^T \nabla f(x_i) W_g \|^2_2 + \mathcal{O}(E_{W, b_*} \| \Delta_x \|_2^4) \tag{25}
\]

Substitute Eq. (25) into the definition of \( \ell_{\Delta, A^{DL}_g} (g \circ f) \), then

\[
\ell_{\Delta, A^{DL}_g} (g \circ f) := \frac{1}{n} \sum_{i=1}^n E_{W, b_*} \left[ \ell (g \circ f(W_* x_i + b_*), y_i) \right] = \ell_{\Delta, A} (g \circ f) + \Omega_{A^{DL}_g} + \mathcal{O}(\Delta_x^3) \tag{26}
\]

The proof is complete by Eq. (21) and Eq. (26).

**Interpretation.** \( \Omega_{A^{DL}} \) and \( \Omega_{A^{DL}} \) turn out to be: 1) \( \Omega_{A^{DL}} \) is a weighted trace expectation dependent on the Hessian matrix of \( f \); 2) \( \Omega_{A^{DL}} \) is equivalent to \( \Omega_{A^{DL}} \) together with the summation of two norm expectations dependent on \( \nabla f \). Therefore, the data-level DA algorithms \( A^{DL} \) and \( A^{DL} \) are expected to regularize \( f \) so that the \( f \) function class \( F_A^{DL} \) enabled by \( A^{DL} \in \{ A^{DL}, A^{DL} \} \) would be reasonably expected as a subset of \( F_A \) enabled by general training algorithm \( A \).

**Sufficient conditions.** Combined with Theorem 2.9, the sufficient conditions indicated here to tighten the upper bound \( d_{F_A}(D_S^0, D_T^0) \) of the relative transferability \( \tau (A; D_S, D_T) \) are: data-level DA (\( A^{DL} \)) with DA parameters satisfying that 1) \( E_{W_*} [W_*] = 1_m \); 2) \( E_{b_*} [b_*] = 0_m \); 3) \( \mathcal{O}(\Delta_x) \approx 0, \forall j \in N_+, j \geq 3 \); 4) \( W_* \) and \( b_* \) are independent.

**Empirical verification.** We further provide empirical verification in Section 4 for the sufficient conditions above, investigating the concrete cases of DA methods: 1) Gaussian noise satisfies the sufficient conditions, then we empirically show that Gaussian noise improves domain transferability while robustness decreases a bit (Figure 5); 2) Rotation, which rotates input image with a predefined fixed angle with predefined fixed probability, violates \( E_{W_*} [W_*] = 1_m \), and we empirically show that rotation barely affect domain transferability (Figure ?? in Appendix ??); Translation, which moves the input image for a predefined distance along a pre-selected axis with fixed magnitude, violates \( E_{b_*} [b_*] = 0_m \) (Figure ?? in Appendix ??).

**Corollary B.3.** If the neural network in Theorem B.2 is activated by Relu or Max-pooling, then Theorem B.2 becomes

\[
\ell_{\Delta, A^{DL}_g} (g \circ f) = \ell_{\Delta, A} (g \circ f) + \Omega_{A^{DL}_g} + \mathcal{O}(\Delta_x^3),
\]

where \( \Omega_{A^{DL}_g} = 0 \); \( \Omega_{A^{DL}_g} = \frac{1}{n} \sum_{i=1}^n \left[ E_{W_*} \| x_i^T \Delta_{W_g} \nabla f(x_i) W_g \|^2_2 + E_{b_*} \| b_*^T \nabla f(x_i) W_g \|^2_2 \right] \).

**Proof.** Denote an \( L \)-layer NN \( g \circ f(x) := W_g^T \cdot z^{(L-1)}, \) where \( z^{(l)} := \sigma^{(l-1)}(W^{T}_{l-1} \cdot z^{(l-1)}), l = 1, 2, 3, ..., L - 1; \) Define that \( \sigma^{(0)}(W^{T}_{0} \cdot z^{(0)}) := x; \) then \( \nabla^2 (g \circ f(x)) = 0 \) (B.2 of (Zhang et al., 2020)). Since \( \nabla^2 (g \circ f(x)) = W_g^T \cdot \nabla^2 f(x), \) we have \( \nabla^2 f(x) = 0. \)
Corollary B.3 analyzes special cases (Relu/Max-pooling activation) of Theorem B.2, giving notably different regularization effect: in these cases the $A_{DL}^L$ (average the prediction) fails as a regularizer, therefore, doesn’t fulfill our sufficient conditions for improving domain transferability (Theorem 2.9); $A_{DL}^L$ (average the loss) only reserves the regularization on $\nabla f$-dependent norms, but no longer regularizes $\mathcal{H}_f(x)$. Since $A_{DL}^L$ still induces regularization, the induced sufficient conditions analyzed after Theorem B.2 for promoting domain transferability won’t be affected.

Remark. Comparison and connections with related work. On the empirical end, recent work uncovers that heuristic DA can replace explicit regularization mechanisms (dropout, weight decay, etc.) (Hernández-García & König, 2018a,b; Zhang et al., 2021). On the theoretical end, there has been a line of work on understanding the DA-induced regularization, including the branches of 1) regularization from specific methods such as mixup (Carratino et al., 2020; Zhang et al., 2020; Greenewald et al., 2021), random noise (Bishop, 1995), adversarial examples (Szegedy et al., 2013), etc.; 2) DA-induced regularization on the variance at the feature or output level (Leen, 1995; van der Wilk et al., 2018; Dao et al., 2019; Chen et al., 2020b); 3) regularization on Hessian-based complexity (LeJeune et al., 2019). Our analysis in this section contributes uniquely in that: 1) we consider a general DA family of linear transformation (Perez & Wang, 2017), which can be extended to most of the previously analyzed specific DA mechanisms; 2) Besides data-level DA, we also investigate feature-level DA (DeVries & Taylor, 2017) which shows advantages in empirical performance but lacks theoretical support. 3) Rather than demonstrating the regularization effect abstractly at the feature or output level, our results indicates data-dependent $l_2$ regularization on the DA transformation parameter and Jacobian of the model under concrete applicable sufficient conditions.

C. Adversarial Training as a Regularizer

In this section, we show, under certain conditions, why adversarial training may improve domain generalization by viewing adversarial training as a function class regularizer.

We first provide some notation. Let

$$\mathcal{F} = \{ f_\theta(\cdot) = W^L \phi^{L-1}(W^{L-1}\phi^{L-2}(\ldots) + b^{L-1}) + b^L \}$$

where $\phi^j$ are activations, $W^j, b^j$ are weight matrix and bias vector, $\theta$ is the collection of parameters (i.e. $\theta = (W^1, b^1, \ldots, W^L, b^L)$). For the rest of the article, assume that $\phi^j$ are just ReLUs.

Now fix $x \in \mathcal{X}$. Define the preactivation as

$$\tilde{x}^1 := W^1 x + b^1$$
$$\tilde{x}^j := W^j \phi^{j-1}(\tilde{x}^{j-1}) + b^j, j \geq 2$$

Define the activation pattern $\phi_x := (\phi^1_x, \ldots, \phi^{L-1}_x) \in \{0, 1\}^m$ such that for each $j \in [L - 1]$

$$\phi^j_x = 1(\tilde{x}^j > 0)$$

where 1 is applied elementwise.

Now, given an activation pattern $\phi \in \{0, 1\}^m$, we define the preimage $X(\phi) := \{ x \in \mathbb{R}^d : \phi_x = \phi \}$
Adversarially Robust Models may not Transfer Better: Domain Transferability from the View of Regularization

Theorem C.1. *(In the proof of theorem 1 in (Roth et al., 2020))*

Let $\epsilon > 0$ s.t. $B^\epsilon_p(x) \subset X(\phi_x)$ where $B^\epsilon_p(x)$ denotes the $l_p$ ball centered at $x$ with radius $\epsilon$. Let $p = \{1, 2, \infty\}$ and $q$ be the Holder conjugate of $p$ (i.e. $\frac{1}{p} + \frac{1}{q} = 1$). Then

$$\mathbb{E}_{(x,y) \sim P}[l(y, f(x)) + \lambda \max_{x^* \in B^\epsilon_p(x)} \|f(x) - f(x^*)\|_q] = \mathbb{E}_{(x,y) \sim P}[l(y, f(x)) + \lambda \cdot \epsilon \max_{v^* : \|v^*\|_p \leq 1} \|J_f(x)v\|_q]$$

**Interpretation:** This theorem provides an equivalence between the objective functions for adversarial training (left term) and jacobian regularization (right term). We give some intuition on the size of $\epsilon$. Let us first consider a shallow 2 layer network $f(x) = W^2 \phi(W^1 x + b^1)$. Suppose $W^2 \in \mathbb{R}^{m_2 \times m_1}$ and $W^1 \in \mathbb{R}^{m_1 \times d}$. Given a matrix $M$, let $M_j$ denote the $j$th row of $M$. We study the activation pattern $\phi_x$ which equals

$$\phi_x = (\phi_x^1) = \begin{pmatrix} 1 \{W^1_1 x + b^1_1\} \\ \vdots \\ 1 \{W^1_{m_1} x + b^1_{m_1}\} \end{pmatrix}$$

We wish to compute the largest radius $\epsilon$ such that the activation pattern $\phi_x$ is constant within $B^\epsilon_p(x)$. This is simply the distance from $x$ to the closest hyperplane of the form $H_{W^1_j, b^1_j} = \{x \in \mathbb{R}^d : W^1_j x + b^1_j = 0\}$ where $j = 0, \ldots, m_1$ (i.e. $\epsilon = \min_j \text{dist}(x, H_{W^1_j, b^1_j})$). In particular, if $W^1 = I_d \times d$ and $b^1 = 0$, $\epsilon = \min_j \|x_j\|$. Furthermore, we note that $\epsilon$ is nondecreasing as a function of the number of layers. However, it has been observed empirically in (Roth et al., 2020) that approximate correspondence holds in a much larger ball.

**Definition C.2.** *(source and target function class)* Let $G^S, G^T$ be fine tuning function classes for source and target domains, respectively. We define the class of source models as

$$\mathcal{H}^S = G^S \circ \mathcal{F} = \{g^S \circ f_\theta : g^S \in G^S, f_\theta \in \mathcal{F}\}$$

and the class of target models as

$$\mathcal{H}^T = G^T \circ \mathcal{F} = \{g^T \circ f_\theta : g^T \in G^T, f_\theta \in \mathcal{F}\}$$

**Definition C.3.** *(empirical training objective with jacobian regularization)* Let $\lambda, \epsilon > 0$. Take any hypothesis $h_\theta = g^S \circ f_\theta \in \mathcal{H}^S$. Let $\hat{R}(h_\theta) = \frac{1}{n} \sum_{i=1}^n \ell(h_\theta(x_i), y_i)$ denote the empirical risk where $\ell(\hat{y}, y) = \|\hat{y} - y\|^2$. We define the empirical training objective with jacobian regularization as

$$\text{Obj}^A_\lambda(h_\theta) = \hat{R}(h_\theta) + \frac{\lambda \cdot \epsilon}{n} \sum_{i=1}^n \|J_{h_\theta}(x_i)\|_2$$

**Theorem C.4.** *Fix regularization strength $\lambda > 0$. Define*

$$\mathcal{F}^A_\lambda = \{f^A_\theta \in \mathcal{F} : \exists g^S \in G^S \text{ s.t. } \text{Obj}^A_\lambda(g^S \circ f^A_\theta) \leq \text{Obj}^A_\lambda(0)\}$$

*where 0 denotes the zero function (i.e. the class of feature extractors that outperform the zero function). Suppose $(x, y) \in \mathcal{X} \times \mathcal{Y}$ is bounded such that $\max(\|x\|_{\infty}, \|y\|_2) \leq R$. Fix $\delta > 0$. Suppose we additionally restrict our fine tuning class models to linear models where

$$G^S = \{W : W \in \mathbb{R}^{d \times n}, n \geq 1, \min_j \|W_j\|_2 \geq \delta\}$$

(where $W_j$ is the $j$th column of $W$)

$$G^T = \{W : W \in \mathbb{R}^{d \times n}, n \geq 1\}$$

*(Here we are abusing notation to let $g^S \in G^S$ to denote the last linear layer as well as the fine tuning function).*

*Then for $0 \leq \lambda_1 < \lambda_2$

$$\mathcal{F}^A_{\lambda_2} \subsetneq \mathcal{F}^A_{\lambda_1} \subseteq \mathcal{F}$$

*(where $\subsetneq$ denotes proper subset). In particular, if $H^A_{\lambda_1} = G^T \circ \mathcal{F}^A_\lambda$, we have

$$\mathcal{H}^A_{\lambda_2} \subseteq \mathcal{H}^A_{\lambda_1} \subseteq \mathcal{H}^T$$

*where $\subseteq$ denotes proper subset.*
Interpretation:
At the high level, this theorem captures the idea that minimizing the empirical risk with jacobian regularization puts a constraint on the set of feature extractors. In particular, $\mathcal{F}_A^\lambda$ represents the potential class of feature extractors we select after training with jacobian regularization. Therefore, the class of fine tuned models $H_{A,T}^\lambda$ with feature extractors trained with jacobian regularization for the target domain is smaller than the class of fine tuned models $H$ with feature extractors trained without any regularization. Furthermore, we show that the space of feature extractors shrinks as we increase the regularization strength $\lambda$. Since we showed in section 2.2 that smaller function classes have smaller $d$ constraint on the set of feature extractors. In particular, $d$ reduces as we increase $\lambda$. To connect back to adversarial training, if $\epsilon$ satisfies the hypothesis in theorem C.1, we have that

$$E_{(x,y) \sim P}[f(y, f(x)) + \lambda \max_{x \in B(x)} \|f(x) - f(x^*)\|_q] = E_{(x,y) \sim P}[l(y, f(x)) + \lambda \cdot \epsilon \max_{v^* : \|v^*\|_p \leq 1} \|Jf(x)v\|_q]$$

Therefore, minimizing the training objective with jacobian regularization is equivalent to minimizing the adversarial training objective. Using this connection, this theorem essentially shows that, given sufficient number of samples, adversarial training reduces the class of feature extractors which in turn reduces $d_{F_A}$.

Finally, we comment on the assumption that $\|g^S\| > \delta$. Since $\delta > 0$ is arbitrary, we can make it as small as we like and thus we are essentially excluding the 0 last layer which is hardly a constraint on the function class. This assumption is necessary as we are considering regularization on the whole model $g \circ f$ as opposed to regularization on just the feature extractor. Thus, this assumption prevents the scenario where only the last linear layer is regularized.

Proof. We first show that if $0 \leq \lambda_1 < \lambda_2$, we have that

$$\mathcal{F}_{\lambda_2}^A \subseteq \mathcal{F}_{\lambda_1}^A \subseteq \mathcal{F}$$

We first prove the following lemma

Lemma C.5. Suppose the conditions of theorem C.4 are satisfied. Suppose additionally we have that $\mathcal{Y} := \frac{1}{n} \sum_{i=1}^d y_i \neq 0$ (note this occurs with probability 1 if marginal distribution over $\mathcal{Y}$ is continuous). Then for every $\lambda \geq 0$, there exists a function $f_0 \in \mathcal{F}_A^\lambda$ and a fine tuning layer $g^* \in \mathcal{G}^S$ such that

$$\text{Obj}^A_{\lambda}(g^* \circ f_0) = \inf_{g \in \mathcal{G}^S} \text{Obj}^A_{\lambda}(g \circ f_0) = \text{Obj}^A_{\lambda}(0)$$

Choose another $\lambda' \geq 0$ (can equal $\lambda$). Then there exists a $g^{*'} \in \mathcal{G}^S$ be the fine tuning layer such that $\inf_{g \in \mathcal{G}^S} \text{Obj}^A_{\lambda'}(g \circ f_0) = \text{Obj}^A_{\lambda'}(g^{*'} \circ f_0)$ and

$$\frac{1}{n} \sum_{i=1}^n \|J_{g^{*'} \circ f_0}(x_i)\|_2 > 0$$

Proof. Fix $\alpha \geq 0$ and $c > \alpha \cdot R$. Set biases

$$b^1 = \begin{pmatrix} c \\ 0 \\ \vdots \\ 0 \end{pmatrix}, \quad b^j = 0, \quad j \geq 2$$

and weights

$$W^1 = \begin{pmatrix} \alpha & 0 & \ldots & 0 \\ 0 & 0 & \ldots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & \ldots & \ldots & 0 \end{pmatrix}, \quad W^j = \begin{pmatrix} 1 & 0 & \ldots & 0 \\ 0 & 0 & \ldots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & \ldots & \ldots & 0 \end{pmatrix}, \quad j \geq 2$$
Define $x_{i,j}$ be the $j$th entry of the data point $x_i$. Define

\[ \alpha_i := \alpha \cdot x_{i,1} \]
\[ \overline{\alpha} := \frac{1}{n} \sum_{i=1}^{d} \alpha_i \]
\[ \overline{y} := \frac{1}{n} \sum_{i=1}^{d} y_i \]

Now we observe that for a fixed $\lambda \geq 0$ and any $g \in G^S$, we have that

\[
\text{Obj}^A_\lambda(g \circ f_\theta) = \hat{R}(g \circ f_\theta) + \lambda \cdot \epsilon \frac{1}{n} \sum_{i=1}^{n} \|J_{g \circ f_\theta}(x_i)\|_2
\]
\[
= \frac{1}{n} \sum_{i=1}^{n} \left\| (\alpha x_{i,1} + c) \begin{pmatrix} g_{11} \\ \vdots \\ g_{d1} \end{pmatrix} - y_i \right\|_2^2 + \lambda \cdot \epsilon \frac{1}{n} \sum_{i=1}^{n} \alpha \|g_{1i}\|_2
\]
\[
= \frac{1}{n} \sum_{i=1}^{n} \left\| (\alpha_i + c) g_{1i} - y_i \right\|_2^2 + \lambda \cdot \epsilon \alpha \|g_{1i}\|_2
\]

Therefore,

\[
\inf_{g \in G^S} \text{Obj}^A_\lambda(g \circ f_\theta)
\]

is equivalent to solving

\[
\inf_{w \in \mathbb{R}^d : \|w\|_2 \geq \delta} \frac{1}{n} \sum_{i=1}^{n} \left\| (\alpha_i + c) w - y_i \right\|_2^2 + \lambda \cdot \epsilon \alpha \|w\|_2
\]

Utilizing lagrange multipliers, we find the minimizer is

\[
w = \delta \cdot \frac{\overline{y}}{\|\overline{y}\|}
\]

when $c \geq \|\overline{y}\|_\delta^2$.

Now consider the function

\[
S(c, \alpha) = \frac{1}{n} \sum_{i=1}^{n} \left\| (\alpha \cdot x_{i,1} + c) g_{1i} - y_i \right\|_2^2 + \lambda \cdot \epsilon \alpha \|g_{1i}\|_2
\]

Note that this function is continuous with respect to the input $(c, \alpha)$. Now fix $\alpha = 0, c = \|\overline{y}\|_\delta^2$. Set $w = \delta \cdot \frac{\overline{y}}{\|\overline{y}\|}$. Then we have that

\[
S\left(\frac{\|\overline{y}\|_\delta^2}{\delta}, 0\right) = \frac{1}{n} \sum_{i=1}^{n} \|\overline{y} - y_i\|_2^2 < \frac{1}{n} \sum_{i=1}^{n} \|y_i\|_2^2 = \text{Obj}^A_\lambda(0)
\]

The inequality comes from the fact that we assumed $\overline{y} \neq 0$ and noting that $\overline{y}$ is the minimizer of the function $p(z) = \frac{1}{n} \|z - y_i\|_2^2$. Continuity of $S$ ensures that there exists $\alpha_0 > 0$ such that

\[
S\left(\frac{\|\overline{y}\|_\delta^2}{\delta}, \alpha_0\right) < \frac{1}{n} \sum_{i=1}^{n} \|y_i\|_2^2 = \text{Obj}^A_\lambda(0)
\]
Now consider \( U(t) = S((1 + t)\frac{\|y\|_2}{\delta}, (1 + t)\alpha_0) \) for \( t \geq 0 \). Note that \( U \) is continuous with respect to \( t \). Furthermore, we note that \( t \to \infty \) implies \( U(t) \to \infty \) which implies there exists some time \( t = T_f \) such that \( U(T_f) > Obj^A_{\lambda_1}(0) \). Therefore, by the intermediate value theorem, there exists a time \( t = T \) such that \( U(T) = Obj^A_{\lambda_1}(0) \). Finally, set \( c = (T + 1)(\frac{\|y\|_2}{\delta})_i \), \( \alpha = (T + 1)\alpha_0 \), and \( g^* \) as the matrix where \( g^*_1 = \delta \cdot \frac{y}{\|y\|_2} \) and 0 for the other columns. By equation 27 and equation 28 we have

\[
Obj^A_{\lambda_1}(g^* \circ f_\theta) = \inf_{g \in G^S} \ Obj^A_{\lambda_1}(g \circ f_\theta) = U(T) = Obj^A_{\lambda_1}(0)
\]

Furthermore, if we choose another \( \lambda' > 0 \), since \( c = (T + 1)(\frac{\|y\|_2}{\delta})_i > \frac{\|y\|_2}{\delta} \) by equation 28, we have that

\[
Obj^A_{\lambda_1}(g^{*'} \circ f_\theta) = \inf_{g \in G^S} \ Obj^A_{\lambda_1}(g \circ f_\theta)
\]

and

\[
\frac{1}{n} \sum_{i=1}^{n} \|J_{g^{*'} \circ f_\theta}(x_i)\|_2 = \alpha \|g^{*'}\|_2 = \alpha \delta
\]

which is nonzero as \( \delta > 0 \) and \( \alpha = (T + 1)\alpha_0 > 0 \).

\[ \square \]

**Proof of C.4**

Clearly, we have \( F^A_{\lambda_2} \subset F^A_{\lambda_1} \). If we can show that \( f_\theta_1 \not\in F^A_{\lambda_2} \) then we have \( F^A_{\lambda_2} \subset \subset F^A_{\lambda_1} \).

Using lemma C.5 we can find \( f_\theta_1 \in F^A_{\lambda_1} \) such that

\[
\inf_{g \in G^S} \ Obj^A_{\lambda_1}(g \circ f_\theta_1) = Obj^A_{\lambda_1}(0)
\]

In addition lemma C.5 guarantees minimizers \( g^*_1 \) and \( g^*_2 \) such that

\[
Obj^A_{\lambda_1}(g^*_1 \circ f_\theta_1) = \inf_{g \in G^S} \ Obj^A_{\lambda_1}(g \circ f_\theta_1) \quad \text{and} \quad \frac{1}{n} \sum_{i=1}^{n} \|J_{g^*_1 \circ f_\theta_1}(x_i)\|_2 > 0
\]

\[
Obj^A_{\lambda_2}(g^*_2 \circ f_\theta_1) = \inf_{g \in G^S} \ Obj^A_{\lambda_2}(g \circ f_\theta_1) \quad \text{and} \quad \frac{1}{n} \sum_{i=1}^{n} \|J_{g^*_2 \circ f_\theta_1}(x_i)\|_2 > 0
\]

Thus, we have that

\[
Obj^A_{\lambda_1}(g^*_2 \circ f_\theta_1) = \hat{R}(g^*_2 \circ f_\theta_1) + \lambda_2 \cdot \frac{1}{n} \sum_{i=1}^{n} \|J_{g^*_2 \circ f_\theta_1}(x_i)\|_2
\]

\[
> \hat{R}(g^*_2 \circ f_\theta_1) + \lambda_1 \cdot \frac{1}{n} \sum_{i=1}^{n} \|J_{g^*_2 \circ f_\theta_1}(x_i)\|_2 \quad \text{since} \quad \lambda_2 > \lambda_1
\]

\[
\geq \hat{R}(g^*_1 \circ f_\theta_1) + \lambda_1 \cdot \frac{1}{n} \sum_{i=1}^{n} \|J_{g^*_1 \circ f_\theta_1}(x_i)\|_2 \quad \text{def of} \quad g^*_1
\]

\[
= Obj^A_{\lambda_1}(0) \quad \text{lemma C.5}
\]

Thus \( f_\theta_1 \not\in F^A_{\lambda_2} \) which implies \( F^A_{\lambda_2} \subset \subset F^A_{\lambda_1} \). It remains to show for \( \lambda_1 \geq 0 \), we have that \( F^A_{\lambda_1} \subset \subset F \).

Consider any \( g \in G^S \). For \( j \in [L] \), define \( W^j \) as the weight matrix where \( W^j = I_{d \times d} \) (identity matrix) for \( j \in [L - 1] \) and let the final weight \( W^L = B \cdot I_{d \times d} \) for some constant \( B > 0 \). Set the bias vectors \( b^j = 0 \) for \( j \geq 2 \). Let the first bias equal
$b^1 = R \cdot 1$ where $1$ is the vector of all $1$’s and $R$ is the upper bound such that $\|x\|_\infty \leq R$. Set $\theta = (W^1, b^1, \ldots, W^L, b^L)$ and let $h_\theta = g \circ f_\theta$

We compute

$$\text{Obj}^A_{\lambda_1}(h_\theta) = \hat{R}(h_\theta) + \lambda_1 \cdot \frac{1}{n} \sum_{i=1}^{n} \|J_{h_\theta}(x_i)\|_2$$

$$= \frac{1}{n} \sum_{i=1}^{n} \|B(x_i + R1) - y_i\|^2 + \frac{1}{n} \sum_{i=1}^{n} \|J_{h_\theta}(x_i)\|_2$$

$$= \frac{1}{n} \sum_{i=1}^{n} \|B(x_i + R1) - y_i\|^2 + B \|g\|_2$$

$$\geq \frac{1}{n} \sum_{i=1}^{n} \|B(x_i + R1) - y_i\|^2 + B\delta$$

We note that sending $B \to \infty$ we get $\text{Obj}^A_{\lambda_1}(h_\theta) \to \infty$ which implies that there exists a $B = B'$ such that $\text{Obj}^A_{\lambda_1}(h_\theta) > \text{Obj}^A_{\lambda_1}(0)$. Setting $B = B'$ implies $f_\theta \notin \mathcal{F}^A_{\lambda_1}$.

D. Extra Experiment Results

D.1. Absolute Transferability vs. Model Robustness

We show the absolute transferability versus robustness of different models in Figure 8,9,10 and 11 respectively.

![Figure 8](image1.png)

Figure 8. Robustness and absolute transferability when we control the norm of last layer with last-layer regularization (LLR) and last-layer orthogonal training (LLOT) with different parameters.

![Figure 9](image2.png)

Figure 9. Robustness and absolute transferability when we regularize the feature extractor with Jacobian Regularization (JR) and weight decay (WD) with different parameters.
Adversarially Robust Models may not Transfer Better: Domain Transferability from the View of Regularization

Figure 10. Robustness and absolute transferability when we use Gaussian noise (Gauss) and posterize (Pos) as data augmentations with different parameters.

Figure 11. Robustness and absolute transferability when we use rescale and blur as data augmentations with different parameters.

D.2. Absolute Transferability vs. Regularization Magnitude

We show the absolute transferability w.r.t. different regularization magnitude in Fig 12,13,14 and 15 respectively. The green dashed line is the transferability of vanilla trained model and the red dashed line is that of adversarially trained model. We can observe that with most single regularization or augmentation, the model transferability can be improved compared with vanilla trained model and sometimes even outperform the adversarially trained ones. In some cases (e.g. jacobian regularize), the performance drops because the larger regularization hurts benign accuracy and therefore the absolute transferability drops.

Figure 12. Absolute transferability when we control the norm of last layer with last-layer regularization (LLR) and last-layer orthogonal training (LLOT) with different parameters. Green dashed line is the transferability of vanilla trained model and red dashed line is that of adversarially trained model.

D.3. Results of Other Model Structures

To further validate our evaluation results, we evaluate the experiments on another model structure. We use a simpler CNN model for CIFAR-10 to SVHN and a more complicated WideResNet-50 for ImageNet to CIFAR-10. The CNN model consists of four convolutional layer with 3 x 3 kernels and 32,32,64,64 channels respectively, followed by two hidden layer with size 256. A 2 x 2 max pooling is calculated after the second and fourth layer. Other settings are the same as in the main text. Note that in some settings the new model cannot converge, and therefore we will omit the result. In addition, Jacobian regularization cannot be applied on WideResNet-50 because of the large memory cost, so we do not include it in
Adversarially Robust Models may not Transfer Better: Domain Transferability from the View of Regularization

**Figure 13.** Absolute transferability when we regularize the feature extractor with Jacobian Regularization (JR) and weight decay (WD) with different parameters. Green dashed line is the transferability of vanilla trained model and red dashed line is that of adversarially trained model.

**Figure 14.** Absolute transferability when we use Gaussian noise (Gauss) and posterize (Pos) as data augmentations with different parameters. Green dashed line is the transferability of vanilla trained model and red dashed line is that of adversarially trained model.

The figures. The results are shown in Figure 16, 17 and 18.

**D.4. Robustness Evaluation with AutoAttack**

Besides PGD attack, we also evaluate the model robustness using the stronger AutoAttack. We use APGD-CE, APGD-T and FAB-T as the sub-attacks in AutoAttack with 100 steps. Since the accuracy will decrease after the stronger attack, we use a slightly smaller $\epsilon = 0.2$ to better visualize the trend. The results are shown in Fig. 19. We can observe that the trend is similar with what we observed before when we used the PGD attack - domain generalization is an effect of regularization and data augmentation, and it is sometimes negatively correlated with model robustness. Also, augmentations like rotation and translation, which violates the sufficient condition, do not improve the domain generalization.

**Figure 15.** Absolute transferability when we use rescale and blur as data augmentations with different parameters for ImageNet. Green dashed line is the transferability of vanilla trained model and red dashed line is that of adversarially trained model.
