Torsion of the vermiform appendix: A rare intraoperative finding

Muhammad Yaman Adi, Mohammad Bader, Ingo Jester

ABSTRACT

Introduction: Torsion of the vermiform appendix is a rare intraoperative diagnosis. The clinical presentation is identical to that of acute appendicitis, with preoperative investigations playing a minimal role. The etiology of the torsion is unclear, though it has been associated with fecoliths, lipomas and mucoceles of the appendix. Case Report: This case report describes a rare presentation of a four-year-old boy with a history and examination classical of acute appendicitis. Intraoperatively, a torsion of the vermiform appendix was found. The clinical presentation and operative intervention are reviewed. Conclusion: Torsion of the vermiform appendix is a rare cause of acute abdominal pain, mimicking acute appendicitis in presentation. Clinicians need to be aware of this intraoperative diagnosis and be able to manage it in the theatre.

Keywords: Torsion, Vermiform appendix, Appendicitis, Pediatric

CASE REPORT

A four-year-old boy was presented with a three-day history of central abdominal pain and vomiting. Pain was localized to the right iliac fossa. On examination, he was pyrexial. He had a tender abdomen with rebound tenderness in the right iliac fossa. He had a past medical history of adenotonsillectomy and grommet insertions.

No hematological or radiological investigations were required. Clinical examination was suggestive of acute appendicitis. Therefore, he was taken to operation theatre for a laparoscopic appendicectomy on the same day.

At the time of operation, he was discovered to have 720 degrees torsion of the vermiform appendix (Figure 1) with ischemic changes in the distal half. A thrombosed vessel was visualized. A perforation was not present. The appendix had adhered to the inner inguinal opening, however a patent orifice was not seen. The appendix

INTRODUCTION

Torsion of the vermiform appendix is a rare intraoperative diagnosis. It was first reported in 1918, which was clinically identical in presentation to acute appendicitis [1]. It has been reported 30 times in the last century, half of which were in pediatric patients [2]. The etiology of the torsion is unclear. Herein, we present a four-year-old boy with acute appendicitis and diagnosed as appendicular torsion.
was then peeled off this area and three endoloops were
applied and appendicectomy was performed. He made
an uneventful recovery and was discharged the following
day. His histopathology was consistent with hemorrhagic
infarction of the appendix.

Histopathology
Macrosopic: The appendix measured 7x1x1 cm
with a congested surface and hemorrhagic attached fat
3x2 cm. On the cut surface the appendix wall was brown
and had hemorrhagic luminal contents.

Microscopic: This confirmed severe acute congestion
of the appendiceal wall associated with extensive mucosal,
subserosal as well as mesoappendiceal hemorrhage. The
mucosa was completely necrotic and focally the necrosis
extended into the muscularis propria. Acute serosal
inflammation was also present.

Diagnostic summary: Hemorrhagic infarction of
the appendix.

DISCUSSION

Even though acute appendicitis is one of the most
common surgical emergencies, torsion of the vermiform
appendix, which mimics acute appendicitis, is a rare
phenomenon. It is unclear how the torsion develops
though several aetiologies have been reported. Some
have described it as a primary event due to the appendix
being of a longer length, having poor fixation and narrow
mesentery. Others have reported cases as a secondary
event due to irregular peristaltic movements of the
appendix [1], inflammation of the distal appendix [3],
or presence of fecoliths, lipomas and mucoceles of the
appendix [4–6]. Mostly, the appendix torsion is in a
clockwise direction (as in this case) [6].

It is difficult to describe the exact cause of the torsion
in this case. We theorized two questions: Was the torsion
a primary event that caused tip inflammation, which then
led it to adhere to the anterior abdominal wall? Or did
the inflammation of the appendix cause the tip to adhere
to the abdominal wall, which then led to the torsion
by secondary means such as poor fixation or bowel
peristalsis? Other secondary factors, such as fecoliths,
lipomas or mucoceles, were not present in this case.

The position of the appendix in these cases is
commonly described as lying free or pelvic [7]. However,
the case reported revealed an appendix that had adhered
to the anterior abdominal wall.

Imaging does not play major role in these cases. One
report described how an ultrasound scan performed twice
showed a distended bowel loop on both the occasions
[8], but still underwent an operation for diagnostic and
therapeutic measures. This patient had the same outcome
as the case reported above, though investigations were
not performed in our case.

CONCLUSION

Torsion of the vermiform appendix is a rare
finding in patients presenting as an acute appendicitis.
The diagnosis remains an intraoperative one, with
preoperative investigations playing a minimal role. The
torsion can be caused by a primary or secondary event.
Nonetheless, they will have an appendectomy performed,
and therefore the operating surgeon needs to be aware of
this intraoperative finding and how to manage it.
