An Asymmetric Silicon Grating Dual-Narrow-Band Perfect Absorber Based on Dielectric-Metal-Dielectric Structure

Feng Xu, Lixia Lin, Dongwei Wei, Jing Xu and Jun Fang*

College of Chemical Engineering and Materials Science, Quanzhou Normal University, Quanzhou, China

With the exhaustion of world energy, new energy has become the most important content of each country’s development strategy. How to efficiently use solar energy has become a research hotspot in current scientific research. Based on surface plasmon resonance and Fabry-Perot (FP) cavity, this paper proposes a design method of asymmetric silicon grating absorber, and uses finite difference time domain (FDTD) method for simulation calculation. By adjusting the geometric parameters, the asymmetric silicon grating absorber realizes two narrow-band absorption peaks with absorption greater than 99% in the optical wavelength range of 3,000–5,000 nm, and the absorption peak wavelengths are $\lambda_1 = 3,780$ nm and $\lambda_2 = 4,135$ nm, respectively. When the electromagnetic wave is incident on the surface of the metamaterial, it will excite the plasmon resonance of the metal to form a surface plasmon (SP) wave. When the SP wave propagates along the x axis, the silicon grating can reflect the SP wave back and forth. When the frequency of the SP wave and the incident light are equal, it will cause horizontal FP coupling resonance, resulting in different resonance wavelengths. This paper also discusses the influence of geometric parameters, incident angle and polarization angle on the performance of silicon grating absorbers. Finally, the sensing performance of the structure as a refractive index sensor is studied. The absorber can be used for various spectral applications such as photon detection, optical filtering and spectral sensing.

Keywords: surface plasmon resonance, fabry-perot resonance, asymmetric silicon grating, dual-narrow-band, perfect absorption

INTRODUCTION

Surface plasmon resonance (SPR) is a non-radiative electromagnetic mode formed by the coupling of incident photons and free electrons on the metal surface (Cao et al., 2014). It is an excited state that locally propagates on the medium and metal surface. It is limited to the surface of the medium and metal, where the surface intensity is the highest, and it gradually attenuates to both sides in the direction perpendicular to the surface (Deng et al., 2015; Chen et al., 2021a; Li-Ying et al., 2021). Its propagation characteristics are related to the incident light source, the metal medium material and the surrounding refractive index (jiang et al., 2021a). SPR provides a foundation for micro-nano applications due to its unique advantages, including biosensing, light field enhancement, solar cells, photocatalysis, Raman enhanced detection, and photodetectors (Liu et al., 2017; Xiao et al., 2017; Li et al., 2018; Chen et al., 2019; Li et al., 2020a; Zhao et al., 2021).
Resonance in subwavelength periodic structures has been studied extensively in the last decade. The resonance mode can be excited by the plasmon to affect the transmission, reflection and absorption characteristics of the structure (Ding and Magnusson, 2004; Deng et al., 2018; Jiang et al., 2021b). The near unit absorption of waves is called perfect absorption, and researchers have carried out many studies on perfect metamaterial absorbers (Cheng and Du, 2019; Cheng et al., 2019; Cheng et al., 2020; Cheng et al., 2021). They have many potential applications. Perfect absorbers with wide operating bandwidth are conducive to the application in photon detection, solar energy collection and other fields (Zhu et al., 2014; Rosenberg et al., 2019; Li et al., 2020b; Li et al., 2021a; Li et al., 2021b; Zhou et al., 2021), while perfect absorbers with narrow operating bandwidth have great advantages in sensing, filtering and selective thermal emission (Liu et al., 2010; Mason et al., 2011; Yi et al., 2020; Chen et al., 2021b; Wang et al., 2021).

In addition, the ultra-narrow bandwidth refractive index sensor based on the perfect absorber has large figure of merit (FOM), and many researchers have proposed such a sensor with good performance (Vafapour and Ghahraloud, 2018; Keshavarz and Vafapour, 2019; Vafapour, 2019; Zhang et al., 2021). Usually, an all-metal structure or a three-layer or multi-layer metal insulator metal (MIM) structure is used to achieve perfect absorption in a narrow band (El-Gohary et al., 2014; Long et al., 2015; Zhang et al., 2015; Long et al., 2016; Elshorbagy et al., 2017). However, due to the incompatibility of these structures with complementary metal oxide semiconductor (CMOS) manufacturing processes, the manufacturing costs are high (Kuznetsov et al., 2016). Therefore, people are paying more and more attention to the realization of narrow-band perfect absorber through the dielectric structure on the metal system (Sharon et al., 1997; Liao and Zhao, 2017; Ren et al., 2019). Compared with the perfect metal absorber, this absorber can save manufacturing costs (Cui et al., 2014). This type of absorber usually has a dielectric waveguide layer. They can produce ultra-narrow absorption, but the structures are complex. Therefore, in order to optimize the structure, we can place the dielectric waveguide layer on the metal substrate or metal base film. For example, in 2016, Callewaert et al. proposed a narrow-band absorber based on a silver film dielectric nanodisk array (Callewaert et al., 2016).

In this paper, an asymmetric silicon grating absorber is designed based on the medium-metal-medium structure. Through the adjustment of geometric parameters, the dual-narrow-band perfect absorption is finally achieved. Asymmetric silicon grating is designed by using three unevenly spaced silicon strips in each cell. This asymmetric structure makes the absorber support horizontal FP resonance. The plane plasmon wave excited by the TM polarization (incident electric field polarized along the x-axis) incident can produce different FP coupling resonances with the incident light, resulting in two absorption peaks. When the incident angle is changed, the two absorption peaks show insensitive characteristics in the range of 0°–20°. In addition, the influence of geometric parameters and polarization angle on the performance of the absorber are briefly discussed. Finally, when this structure is used as a sensor, it has high sensitivity and quasi-linear response. It can be used in a variety of multi-spectral applications, such as filtering, photon detection, and spectral sensing.

**MATERIALS AND METHODS**

**Figure 1** shows the structure of the dual-narrow-band grating absorber we designed. It is made of a quartz substrate and a silicon grating on the surface of a gold film. Incident light source is TM plane light wave, and the direction of light source is perpendicular to grating plane. The period of the grating is A, and there are three silicon gratings with unequal spacing in each period. The three silicon grating structures in a unit period make the grating as a whole asymmetrical structure. h₁ represents the height of the silicon grating, h₂ represents the height of the gold thin layer, w represents the width of the silicon grating, and d₁ and d₂ represent the center spacing of adjacent silicon gratings. The parameters of gold and silicon come from Palik (Palik, 1998),
and the refractive index of quartz is 1.45. In the case of normal light wave incidence, we calculate the reflection (R), transmission (T) and absorption (A) as shown in Figure 2. The geometric parameters of the structure are $A = 3,000$ nm, $h_1 = 630$ nm, $b_2 = 90$ nm, $w = 300$ nm, $d_1 = 560$ nm, and $d_2 = 880$ nm, respectively. We can notice from Figure 2 that the range of the light waveband is $3,000$–$5,000$ nm, where the $T$ is basically zero. The first absorption peak that appears is named $\lambda_1$ ($\lambda_1 = 3,780$ nm), and its full width at half maximum (FWHM) is $40$ nm. The second absorption peak, we named $\lambda_2$ ($\lambda_2 = 4,135$ nm, FWHM = $39$ nm). The absorption of the two resonance peak wavelengths exceeds $99\%$.

RESULTS AND DISCUSSION

In order to analyze the physical mechanism of resonance, we simulated and calculated the electric and magnetic field distributions at $\lambda_1 = 3,780$ nm and $\lambda_2 = 4,135$ nm on the XOZ plane. Figures 3A,B respectively show the electric field and magnetic field distribution at $\lambda_1$. We have observed that the electric field is distributed at the top corners of the slits with small silicon grating spacing, and the magnetic field is mainly distributed between the slits with small silicon grating spacing. Figures 3C,D respectively show the electric field and magnetic field distribution at $\lambda_2$. The difference from $\lambda_1$ is that the electric field is distributed on the surface of the three silicon gratings, and the magnetic field is mainly distributed in the slits of the two silicon gratings with a larger silicon grating spacing. This indicates that these two resonance peaks are derived from the coupling between the SPR of the metal and the resonance of the FP cavity (Cheng et al., 2015; Lv et al., 2018; He et al., 2020). The resonant peak at $\lambda_1$ is mainly related to the FP resonance between gratings with a short pitch ($d_1$), and the resonant peak at $\lambda_2$ is mainly derived from the FP resonance between gratings with a large pitch ($d_2$).
Then in order to explore the influence of the asymmetric silicon grating structure on the absorption performance, we used the controlled variable method to change the geometric parameters. Figures 4A,B respectively show the influence of the change of the period and the geometric parameters of the silicon grating pitch on the absorption performance of the silicon grating. From Figure 4A, we can observe that as the period length increases, the first absorption peak ($\lambda_1$) of the silicon grating gradually increases. With the increase of the period length, the two absorption peaks show red shift, and the longer the period length is, the farther the wavelength distance of the two absorption peaks is. At the same time, we noticed that the FWHM slowly decreases with the increase of the period. Figure 5B shows that we change the smaller silicon pitch of the asymmetric silicon grating (d₁) as the geometric parameter variable. Through Figure 4B, we found that when the silicon grating pitch is 60 nm, the absorption of the two absorption peaks is not high, and the FWHM is large. As the spacing of the silicon grating increases, the absorption gradually increases, the FWHM gradually decreases, and the two absorption peaks appear blue shift. At the same time, we can observe that the change of the silicon grating pitch has a greater influence on the first absorption peak, indicating that the $\lambda_1$ peak is sensitive to the change of the grating pitch, that is, the absorption peak is sensitive to the cavity length change.

Figures 5A,B respectively show the influence of asymmetric silicon grating thickness and silicon grating width geometric parameters (d₂) on the absorption performance of the silicon grating. From Figure 5A, we can observe that as the thickness of the silicon grating increases, the absorption of the two absorption peaks shows a trend of first increasing and then decreasing. This is because when the thickness of the silicon grating is small, it weakens the FP resonance and reduces the absorption of light. When the thickness increases to a certain size (630 nm), that is, when the thickness reaches the critical value, the absorption will no longer increase. At the same time, both absorption peaks appear red shift. And the distance between the two absorption peaks gradually increases, because each silicon grating plays a different role in the FP cavity. From Figure 5B, we also found that as the width of the silicon grating increases, the two absorption peaks first increase and then decrease, the resonance wavelength appears red-shifted, and the FWHM gradually increases.
However, unlike the trend of silicon grating thickness changes, as the silicon thickness changes, the distance between the two absorption peaks becomes smaller and smaller. The reason is the same as the thickness of the silicon grating: each silicon grating acts as a mirror, and their role is different.

In addition, we also studied the spectral response of the asymmetric silicon grating structure under different incident angles and polarization angles, and the results are shown in Figure 6. It can be seen that the intensity and position of the absorption peaks in the range of 0°–20° incident angle do not change, which indicates that the absorber is not sensitive to the incident angle in this range. When the incident angle exceeds 20°, the absorption will be greatly reduced due to the wave vector mismatch. When changing the polarization angle of the beam...
from 0° (TM polarization) to 90° (TE polarization), the results are shown in Figure 6B. It can be clearly found that the extinction intensity of the two peaks decreases with the increase of the polarization angle. At the same time, we also noticed that when the incident plane wave is TE polarization, two new resonance peaks appear, which are caused by phase resonance (Qin et al., 2020; Su et al., 2021). The electric field generated at this time has a phase difference of π, which causes the far field to produce coherent cancellation, thereby generating two new peaks.

Finally, in order to explore the performance of asymmetric silicon grating as a refractive index sensor, we conduct research by changing its environmental refractive index. Figure 7A shows the absorption spectrum of the silicon grating when the refractive index of the surrounding environment changes. Since our silicon grating structure belongs to narrow-band absorption, we set the refractive index to change from 1.0 to 1.1 with a gradient of 0.02. From the figure, we can observe that as the refractive index of the environment increases, the two absorption peaks appear red-shifted, but the peaks of the two absorption peaks remain basically stable. At the same time, we found that the FWHM of the two absorption peaks did not change much, the change range was between 1 and 2nm, and we took the average value of the FWHM. Figures 7B,C show the corresponding absorption peak wavelengths of the two absorption peaks of \( \lambda_1 \) and \( \lambda_2 \) under the change of refractive index. The oblique line data is obtained by our linear fitting process. According to the formula \( S = \Delta \lambda/\Delta n \) and \( \text{FOM} = S/\text{FWHM} \), the sensitivity (S) and FOM of the silicon grating can be calculated (Chen et al., 2013; Cai et al., 2014; Tang et al., 2018; Wu et al., 2020; Chen et al., 2021c). According to the formula, we can find that the slope of the straight line is the S. The S of the absorption peaks at \( \lambda_1 \) and \( \lambda_2 \) are 2,500 nm/RIU and 3,000 nm/RIU. The FWHM are 40 nm and 39 nm. FOM are 62.5 and 76.9. It can be found that this structure has high sensitivity, so it can be applied in the field of refractive index sensors.

CONCLUSION

In conclusion, we fully demonstrate the absorption of dielectric structures on metal systems, based on the gold mold. By adjusting the geometric parameters, the asymmetric silicon grating absorber achieves the best absorption efficiency, two narrow-band absorption peaks in the range 3,000–5,000 nm light wave segments, the absorption peaks are \( \lambda_1 = 3,780 \text{ nm} \) and \( \lambda_2 = 4,135 \text{ nm} \). And the absorption value is over 99%. We find that the distance between asymmetric gratings and the length of periods are changed, the absorption and FWHM of the absorption peak are the most affected. At the same time, it is found that the extinction intensity of the two peaks decreases with the increase of polarization angle. The structure has good sensing performance and high sensitivity. For the absorption peak of \( \lambda_1 \), \( S = 2,500 \text{ nm}/\text{RIU} \) and \( \text{FOM} = 62.5 \). For the absorption peak of \( \lambda_2 \), \( S = 3,000 \text{ nm}/\text{RIU} \) and \( \text{FOM} = 76.9 \).
