Cicatricial ectropion
Madarosis
Panitumumab

ABSTRACT

Purpose: To report a case of cicatricial ectropion and madarosis with the use of anti-epidermal growth factor receptor medication panitumumab.

Observations: An 82-year-old man with metastatic colorectal cancer presented with cicatricial ectropion and madarosis after starting panitumumab, an anti-epidermal growth factor receptor medication used to treat metastatic colorectal cancer. His findings resolved several weeks after discontinuation of panitumumab and treatment with lubrication and antibiotic/steroid ointment.

Conclusion: This case demonstrates the importance to consider potential medication side effects when treating periocular conditions in patients taking anti-epidermal growth factor receptor (anti-EGFR) agents.

1. Introduction

Panitumumab is a monoclonal antibody targeting the epidermal growth factor receptor (EGFR) and is FDA-approved for use in metastatic colorectal cancer. It has been shown to improve the overall survival in patients with wild-type RAS metastatic colorectal cancer. Normal epithelial cells and cancer cells both express EGFR; therefore, common side effects of EGFR inhibitors include adverse skin reactions such as redness, acneiform dermatitis, itching, and rash. Ocular and periocular side effects are less common; however, dry eye syndrome, blepharitis, trichomegaly, and eyelid rash have been reported. There are very few reported cases of EGFR-related ectropion. We report a case of panitumumab-induced madarosis and cicatricial ectropion.

2. Case report

An 82-year-old Caucasian male with metastatic colon cancer presented with 3-month history of progressively worsening severe eye irritation, bilateral lower eyelid changes and loss of eyelashes. His symptoms began 2 months after his oncologist started him on the chemotherapy regimen FOLFIRI (leucovorin calcium, fluorouracil, and irinotecan hydrochloride) and panitumumab. The patient was subsequently referred for ophthalmic evaluation by his oncologist due to ongoing eye symptoms. On examination, best corrected visual acuity was 20/50 in the right eye and 20/80 in the left eye. Pupillary response, intraocular pressure, motility, and confrontation visual fields were normal. External examination revealed scalp excoriations, cicatricial ectropion of the bilateral lower eyelids, madarosis of bilateral upper and lower eyelids, bilateral upper eyelid ptosis, as well as severe eyelid margin inflammation (Fig. 1). Slit-lamp examination showed trace bilateral conjunctival hyperemia, inferior corneal staining, and nuclear sclerotic cataracts.

The patient was started on neomycin/polymyxin B/dexamethasone ophthalmic ointment three-times a day, and suspicion of panitumumab as the causative agent was communicated with the patient’s oncologist and it was subsequently held. Two weeks after the initial visit, the patient reported improvement in periocular irritation. Eight weeks after the initial visit, there was complete and near-complete resolution of cicatricial ectropion of the right and left lower lids respectively with bilateral significant improvement of the previously noted madarosis and lid margin inflammation (Fig. 2). Three months after initial visit, patient had complete resolution of cicatricial ectropion and his madarosis continued to improve on the left side (Fig. 3). Best-corrected visual acuity improved to 20/25 in the right eye and 20/40 in the left eye. Mild residual senile ectropion remained but was well-managed with artificial tears, warm compresses, and lubricating ointment as needed.

Cicatricial ectropion occurs when there is abnormal contraction or scarring of skin secondary to infectious, inflammatory, chemical, thermal, immunological, or post-surgical changes to the eyelids. The most common adverse reactions caused by anti-EGFR medications are skin reactions, gastrointestinal disorders, fatigue, pyrexia, hypomagnesia, and paronychia. Adverse skin reactions associated with EGFR inhibitors are thought to be caused by direct inhibition of the EGFR in keratinocytes and hair follicles, which interferes with cell survival, proliferation, differentiation, and migration.

Panitumumab is a fully human monoclonal antibody that binds and inhibits EGFRs of both normal epidermal cells and that of tumor cells. It is currently used either as monotherapy or in combination with first- and second-line chemotherapies to treat metastatic wild-type RAS colorectal cancer.

Cicatricial ectropion and trichomegaly have been reported in older-generation anti-EGFR agents such as cetuximab and erlotinib. Ocular adnexal side effects such as cicatricial ectropion and eyelid dermatitis have also been reported with the use fluoropyrimidine and docetaxel. Panitumumab-induced trichomegaly, poliosis, and cicatricial ectropion are rare. However, the combination of cicatricial ectropion and madarosis associated with panitumumab has not been previously described to our knowledge, although is not unexpected given that this has been previously reported with cetuximab.

The use of oral doxycycline and topical ophthalmic steroid/antibiotic ointment have been tried to treat EGFR-inhibitor induced cicatricial ectropion; however, results from randomized clinical trials on the effects of various interventions (i.e. sunscreen, skin moisturizer, topical steroid, oral tetracycline) in the management of EGFR inhibitor-induced skin and periocular toxicity have been equivocal. In our case, the patient had been previously treated with FOLFIRI without experiencing periocular side effects. After a careful discussion of the risks and benefits of discontinuing panitumumab, the patient and his oncologist elected to indefinitely defer this therapy and we managed him with lubrication and topical antibiotic/steroid ointment until complete resolution of his symptoms. We believe that both the discontinuation of panitumumab and aggressive surface lubrication played significant roles in our patient’s recovery.

### 4. Conclusion

In summary, this case serves as an example of a careful review of medications’ side effects can avoid unnecessary and premature surgical intervention in the treatment of cicatricial ectropion associated with anti-EGFR medications. Oncologists, ophthalmologists, and optometrists should be aware of the potential side effects of these medications in order to undertake collaborative management strategies, including altering chemotherapeutic regimens and conservative treatment options when necessary.

### Patient consent

The patient consented to publication of the case in writing.

### Funding

No funding or grant support.

### Authorship

All authors attest that they meet the current ICMJE criteria for Authorship.

### Declaration of competing interest

The authors have no financial disclosure.

### Acknowledgements

None.
