An outbreak of cholera occurred in 1991 in Mexico, where it had not been reported for more than a century and is genetically diverse. Whole-genome sequence analysis to a set of 124 isolates that cholera was transmitted from Africa to Latin America has been proposed in the literature. In this study, we have applied netic relationships. Phylogenetic analysis indicated the six isolates belonged to five distinct phylogenetic clades. One CTX$^{-}$ isolate is ancestral to the 6th and 7th pandemic CTX$^{+}$ V. cholerae isolates. The other CTX$^{-}$ isolate joined with CTX$^{-}$ non-O1/O139 isolates from Haiti and seroconverted O1 isolates from Brazil and Amazonia. One CTX$^{+}$ isolate was phylogenetically placed with the sixth pandemic classical clade and the V. cholerae O395 classical reference strain. Two CTX$^{+}$ El Tor isolates possessing intact Vibrio seventh pandemic island II (VSP-II) are related to hybrid El Tor isolates from Mozambique and Bangladesh. The third CTX$^{+}$ El Tor isolate contained West African-South American (WASA) recombination in VSP-II and showed relatedness to isolates from Peru and Brazil. Except for one isolate, all Mexican isolates lack SXT/R391 integrative conjugative elements (ICEs) and sensitivity to selected antibiotics, with one isolate resistant to streptomycin. No isolates were related to contemporary isolates from Asia, Africa, or Haiti, indicating phylogenetic diversity.

Cholera, a deadly waterborne disease, is caused by Vibrio cholerae and continues to be a health hazard for millions around the world, particularly in developing countries. Of more than 200 “O” serogroups, only V. cholerae O1 and O139 have been associated with cholera epidemics. Serogroup O1 has been classified into two biotypes, classical (CL) and El Tor (ET), the latter linked to the ongoing 7th pandemic first reported in 1961 (1, 2). Although cholera has been endemic in the Ganges Delta region of South Asia for centuries, several countries of sub-Saharan Africa and Latin America were severely affected during the 7th pandemic and subsequently are now considered areas of endemicity (1). That is, cholera appeared in Mexico in June 1991, after the Latin American epidemic had begun along the Peruvian coast in January 1991 (3). The disease soon broke out in neighboring countries...
by 1992, with the exceptions of Uruguay and French Guiana (4). In Mexico, a total of 43,536 cholera cases were reported between 1991 and 1996, with a substantial number of deaths (3). Epidemiological investigations confirmed the association of *V. cholerae* O1 biotype El Tor with the majority of those cholera cases, although the classical biotype was isolated from some cases in Mexico during subsequent years until 1997 (4–7).

It has long been established that *V. cholerae* O1 had caused seven pandemics since 1817, of which the 7th pandemic is the largest, considering its longevity and geographical distribution. *V. cholerae* El Tor replaced the classical biotype of the 6th pandemic and presumably earlier pandemics (1, 8). Variants of El Tor (hybrid El Tor and/or altered El Tor) possessing classical biotype-specific traits have been reported in Asia, Africa, and Latin America (5, 9, 10). Genetic changes (i.e., gain or loss of mobile genetic elements and genomic islands) occur in *V. cholerae* due to its genomic plasticity (11). An example is the emergence of *V. cholerae* O139 in late 1992 in India, which is a non-O1 serogroup that caused a massive outbreak in South Asia and beyond (12, 13).

Since 2001, variants of El Tor have been associated with cholera epidemics globally, including the recent epidemic in Haiti and the Americas (5, 11). The CTXΦ element is a mobile genetic element that is associated with the CTX toxins. The CTXΦ element is a mobile genetic element that is associated with the CTX toxins. The CTXΦ element is a mobile genetic element that is associated with the CTX toxins. The CTXΦ element is a mobile genetic element that is associated with the CTX toxins.

### RESULTS AND DISCUSSION

Variations in CTXΦ-RS1. Four of the six isolates of *V. cholerae* O1 (95412, CP1030, CP1032, and CP1033) were lysogenic CTXΦ positive, while the remaining two isolates (CP1035 and CP1037) lacked CTXΦ (Table 1). Lysogenic CTXΦ contains two gene clusters, a core region and and RS2 element (23, 24). The CTXΦ element encodes proteins associated with CTXΦ replication (RstA), integration (RstB), and regulation (RstR) (23, 24). Satellite phage RS1 carries an additional rstC gene (encoding anti-repressor protein), along with the entire RS2 element that is usually present in the flanking region of CTXΦ in *V. cholerae* El Tor (24). The chromosomal location of CTXΦ and its orientation and copies of CTXΦ may differ among toxigenic *V. cholerae* strains (25–27). The CTXΦ-RS1 array of CP1030 has been shown to be unique, lacking RS1 and carrying a truncated CTXΦ instead of RS1 in the upstream region of CTXΦ (B3 allele) in the large chromosome (Chr I) (7). The *V. cholerae* O1 El Tor strains isolated in Mexico between 2004 and 2008, show the same CTXΦ array (TLC-truncated CTXΦRS1) (7). Moreover, predicted CTXΦ mapping of El Tor isolates associated with the 1990s’ Latin American epidemic in Peru, Mexico, Bolivia, Colombia, and Argentina showed two copies of CTXΦ (B3 allele) together with TLC and RS1 in Chr I (TLC-CTXΦRS1-CTXΦRS1-RS1) (8). CTXΦ arrays, either TLC-truncated CTX-CTXΦRS1 or TLC-CTXΦRS1-CTXΦRS1-RS1 detected in Latin American isolates was not found in El Tor, altered El Tor, or El Tor variants from Asia, Africa, and Haiti that have been studied to date (8, 25–27). However, an isolate from Sweden was found to contain the latter. Recently, genomic analysis of *V. cholerae* O1 showed close relatedness between isolates from Latin America and Angola, but the CTXΦ array was different (8).

### TABLE 1 Characteristics of *Vibrio cholerae* serogroup O1 strains analyzed in this study

| Strain   | Serotype | Biotype  | Source  | Yr of isolation | CTXΦ | Accession no. |
|----------|----------|----------|---------|----------------|------|---------------|
| CP1032   | Ogawa    | El Tor   | Human   | 1991           | +    | ALDA00000000  |
| 95412    | Inaba    | Classical| Human   | 1997           | +    | APFM00000000  |
| CP1033   | Ogawa    | El Tor   | Human   | 2000           | +    | AMRF00000000  |
| CP1037   | Ogawa    | El Tor   | Environment | 2003   | -    | ALDB00000000  |
| CP1035   | Ogawa    | El Tor   | Human   | 2004           | -    | AJRM00000000  |
| CP1030   | Inaba    | El Tor   | Environment | 2008   | +    | ALCZ00000000  |

*Mexico was the country of origin for all strains shown here.*
As shown in Table 2, the rstA and rstB gene sequence of *V. cholerae* 95412 classical is identical to that of the reference *V. cholerae* O395 classical isolate, whereas variation was observed in *V. cholerae* CTX+ El Tor isolates. *V. cholerae* CP1030, CP1032, and CP1033 contained three unique base substitutions in the rstA gene at 927 (T→C), 933 (C→T), and 942 (G→T), compared to *V. cholerae* N16961, CIRS101, and the recent Haitian isolate HCO1. In addition, CP1032 had a base substitution at 315 (T→C) in the rstA gene. Interestingly, all point mutations are synonymous for RstA.

DNA sequence analysis of CP1030, CP1032, and CP1033 at the rstB gene showed a GTA deletion at positions 77 to 79 and polymorphism at positions 90 (A→T), 96 (T→C), 108 (G→A), and 192 (A→G), unlike *V. cholerae* El Tor strains, except for the GTA deletion, which had been reported in Haitian isolates (14).

Virulence gene expression in *V. cholerae* is regulated by ToxR, a transcriptional regulator that binds with the promoter region (between zot and ctxA) located upstream of ctxAB. The heptamer repeat sequences (TTTTGAT) directly influence the affinity of ToxR binding and promote binding of ToxR, which is followed by activation of the ctxAB promoter (28). As shown in Table 2, *V. cholerae* CP1030, CP1032, and CP1033 contain four copies of the heptamer repeat, like El Tor, altered El Tor, and hybrid variants from Asia and Africa. However, they differ from the Haitian isolates in having five repeats (14, 29). The *V. cholerae* 95412 classical isolate contains six copies of the heptamer repeat, unlike the classical *V. cholerae* reference strain O395, which possesses seven copies of the repeat (Table 2).

*Vibrio pathogenicity islands 1 and 2.* *Vibrio* pathogenicity island-I (VPI-1) encodes the toxin-coregulated pilus (TCP) that promotes colonization of intestinal mucosal epithelium, is involved in biofilm formation, and serves as the receptor for the lysogenic CTXΦ (30). Five of the six *V. cholerae* O1 isolates from Mexico contained VPI-1, but CP1035 lacked this gene cluster. As shown in Fig. 1, *V. cholerae* CP1030, CP1032, and CP1033 possess VPI-1 of the seventh pandemic *V. cholerae* El Tor isolates, whereas the genetic organization of VPI-1 of CP1035 is homologous to that of *V. cholerae* 95412 (classical), despite having a genomic island, GI-47, in the upstream region. Interestingly, the tcpA gene, encoding the major pilin subunit (TcpA) of CP1037, is different from the classical and El Tor tcpA genes. The TCP region showed highest level of sequence polymorphism in VPI-1, with tcpA having the most divergence (31). Previous studies reported TcpA had significant differences in the epitope or antigenic structure when classical and El Tor biotype strains were compared (32). Four of the *V. cholerae* O1 isolates, CP1030, CP1032, CP1033, and 95412, contain the complete VPI-2, whereas the other isolates lack VPI-2. VPI-2 comprises several genes, including those encoding sialidase, the type I restriction modification system, and Mu-like prophage protein genes.

*Vibrio seventh pandemic islands.* The *Vibrio* seventh pandemic islands I and II (VSP-I and -II) in *V. cholerae* are characteristically found in El Tor strains, and they serve as a distinguishing marker from classical strains (33). However, a variant of the VSP-II gene cluster has also been detected in *V. cholerae* non-O1/ O139 strains and in *Vibrio mimicus* (34, 35). *V. cholerae* El Tor strains CP1032 and CP1033 from Mexico contained all of the open reading frames (ORFs) in VSP-I and -II, whereas the CTX− isolates CP1035 and CP1037 lack VSP-I and -II, as does the classical strain 95412. CP1030 possesses a variant VSP-II with an insertion between VC0510 and VC0516 (Fig. 2), commonly referred

### Table 2

| Strain          | Gene position | Gene                | Polymorphism at position: | Polymorphism at position: |
|-----------------|---------------|---------------------|---------------------------|---------------------------|

- **CIRS101 Bangladesh 2002 CTXHYBET**: *
- **933 (C→T)**, compared to *V. cholerae* 95412 classical is identical to that of *V. cholerae* O395 classical isolate, whereas variation was observed in *V. cholerae* CTX+ El Tor isolates. *V. cholerae* CP1030, CP1032, and CP1033 contained three unique base substitutions in the rstA gene at 927 (T→C), 933 (C→T), and 942 (G→T), compared to *V. cholerae* N16961, CIRS101, and the recent Haitian isolate HCO1. In addition, CP1032 had a base substitution at 315 (T→C) in the rstA gene. Interestingly, all point mutations are synonymous for RstA.

DNA sequence analysis of CP1030, CP1032, and CP1033 at the rstB gene showed a GTA deletion at positions 77 to 79 and polymorphism at positions 90 (A→T), 96 (T→C), 108 (G→A), and 192 (A→G), unlike *V. cholerae* El Tor strains, except for the GTA deletion, which had been reported in Haitian isolates (14).

Virulence gene expression in *V. cholerae* is regulated by ToxR, a transcriptional regulator that binds with the promoter region (between zot and ctxA) located upstream of ctxAB. The heptamer repeat sequences (TTTTGAT) directly influence the affinity of ToxR binding and promote binding of ToxR, which is followed by activation of the ctxAB promoter (28). As shown in Table 2, *V. cholerae* CP1030, CP1032, and CP1033 contain four copies of the heptamer repeat, like El Tor, altered El Tor, and hybrid variants from Asia and Africa. However, they differ from the Haitian isolates in having five repeats (14, 29). The *V. cholerae* 95412 classical isolate contains six copies of the heptamer repeat, unlike the classical *V. cholerae* reference strain O395, which possesses seven copies of the repeat (Table 2).

*Vibrio pathogenicity islands 1 and 2.* *Vibrio* pathogenicity island-I (VPI-1) encodes the toxin-coregulated pilus (TCP) that promotes colonization of intestinal mucosal epithelium, is involved in biofilm formation, and serves as the receptor for the lysogenic CTXΦ (30). Five of the six *V. cholerae* O1 isolates from Mexico contained VPI-1, but CP1035 lacked this gene cluster. As shown in Fig. 1, *V. cholerae* CP1030, CP1032, and CP1033 possess VPI-1 of the seventh pandemic *V. cholerae* El Tor isolates, whereas the genetic organization of VPI-1 of CP1035 is homologous to that of *V. cholerae* 95412 (classical), despite having a genomic island, GI-47, in the upstream region. Interestingly, the tcpA gene, encoding the major pilin subunit (TcpA) of CP1037, is different from the classical and El Tor tcpA genes. The TCP region showed highest level of sequence polymorphism in VPI-1, with tcpA having the most divergence (31). Previous studies reported TcpA had significant differences in the epitope or antigenic structure when classical and El Tor biotype strains were compared (32). Four of the *V. cholerae* O1 isolates, CP1030, CP1032, CP1033, and 95412, contain the complete VPI-2, whereas the other isolates lack VPI-2. VPI-2 comprises several genes, including those encoding sialidase, the type I restriction modification system, and Mu-like prophage protein genes.

*Vibrio seventh pandemic islands.* The *Vibrio* seventh pandemic islands I and II (VSP-I and -II) in *V. cholerae* are characteristically found in El Tor strains, and they serve as a distinguishing marker from classical strains (33). However, a variant of the VSP-II gene cluster has also been detected in *V. cholerae* non-O1/ O139 strains and in *Vibrio mimicus* (34, 35). *V. cholerae* El Tor strains CP1032 and CP1033 from Mexico contained all of the open reading frames (ORFs) in VSP-I and -II, whereas the CTX− isolates CP1035 and CP1037 lack VSP-I and -II, as does the classical strain 95412. CP1030 possesses a variant VSP-II with an insertion between VC0510 and VC0516 (Fig. 2), commonly referred
to as the West African and South American (WASA) insertion (8). An identical VSP-II gene cluster has been reported in *V. cholerae* isolated in Peru and Angola (36, 37). Conversely, the VSP-II gene cluster in contemporary *V. cholerae* isolates from Asia and Haiti has a 14.4-kb deletion that spans the ORF from VC0495 to VC0512 (CIRS101 type VSP-II) (14, 35, 38). The distribution of the variant VSP-II types among the *V. cholerae* isolates suggests this island contains hot spots highly prone to genetic rearrangement by recombination (35).

**GIs andICEs.** *V. cholerae* O1 isolates from Mexico contain diverse genomic islands (GIs) that differ among the El Tor, classical, and CTX− strains (see Table S2 in the supplemental material). *V. cholerae* El Tor isolates CP1030, CP1032, and CP1033 uniformly contained GI-1 to GI-10 and GI-85. *V. cholerae* CP1033 (14), on the other hand, contains GI-15 in the large chromosome, which encodes the putative integrase found in the Mozambique variant of *V. cholerae* (R-33) and also in hybrid isolates of CP1067 from Bangladesh, that had been isolated in 1991. Moreover, *V. cholerae* CP1030 contains the WASA1 genomic island, which has been reported previously in West African and South American strains (8). *V. cholerae* classical strain 95-122 has GIs typical of the reference classical strain O395, along with GI-11 and GI-21 in the small chromosome (see Table S2). GI-11 encodes the kappa prophage, whereas the function of GI-21 (~34 kb) has not yet been identified. *V. cholerae* CP1035 contains genomic islands that are similar to those of *V. cholerae* non-O1/O139 and differ from classical and El Tor strains. CP1035 contains several previously described genomic islands, including GI-125 and GI-126, encoding a type I restriction modification system and integrase. Interestingly, CP1037 carries GI-36, which has been detected previously in *V. cholerae* non-O1/O139 TM11079-80 and Amazonia, isolated in Brazil. CP1037 also possesses GI-47 in the upstream region of VPI-1, as previously observed in Peruvian *V. cholerae* isolated in 1994 (Fig. 1) and a unique genomic island, GI-112, carrying *umuCD* and a nucleotidyltransferase gene (see Table S2) (11, 14).

The integrating and conjugative elements (ICEs) are self-transmissible mobile genetic elements in bacteria that confer resistance to various antibiotics. SXT is an ~100-kb ICE originally discovered in *V. cholerae* O139 (39). Since the emergence of *V. cholerae* O139 on the Indian subcontinent in 1992, the SXT/R391 ICE has been reported to be present in most clinical *V. cholerae* O1 or O139 strains isolated in Asia and Africa (8). *V. cholerae* isolates carrying the SXT/R391 ICE are resistant to streptomycin, chloramphenicol, sulfamethoxazole, and trimethoprim (39). Re-

![FIG 1](https://example.com/figure1.png) **FIG 1** *Vibrio* pathogenicity island 1 (VPI-1) of *V. cholerae* O1 strains isolated in Mexico and reference El Tor strain N16961. Mexican CTX− *V. cholerae* O1 strain CP1037 contains GI-47 in the upstream region of VPI-1.
Results of recent phylogenetic analysis suggest *V. cholerae* O1 acquired SXT/R391 ICE sometime between 1978 and 1984, before its discovery in *V. cholerae* O139, and it is hypothesized that it provides a selective advantage to *V. cholerae* O1, allowing it to be globally disseminated (8). In the present study, except for CP1035, all of the Mexican isolates lacked the SXT/R391 ICE. The genome sequences of Latin American isolates (INDRE 91/1 [Mexico]; CP1044, CP1046, and CP1047 [Peru]; and IEC224, RC144, and 116059 [Brazil]) are devoid of SXT/R391 ICE. This observation was confirmed by PCR—i.e., except for CP1035, none of the Mexican isolates amplified DNA fragments for primers targeting the SXT integrase gene (*intSXT*) (40). Lack of the SXT/R391 ICE in epidemic strains isolated in Latin America in the 1990s has been reported (8). Absence of the SXT/R391 ICE among *V. cholerae* isolates has also been reported in a recent cholera outbreak in the Philippines (41). Antibiotic susceptibility analyses of the five Mexican isolates, CP1030, CP1032, CP1035, CP1037, and 95412, revealed all were sensitive to penicillin, ampicillin, streptomycin, chloramphenicol, trimethoprim-sulfamethoxazole, tetracycline, kanamycin, erythromycin, nalidixic acid, and ciprofloxacin. *V. cholerae* CP1035 shows resistance only to streptomycin. Despite possessing SXT/R391 ICE, CP1035 was sensitive to antibiotics, suggesting SXT/R391 ICE lacks genes conferring resistance to streptomycin, chloramphenicol, and trimethoprim-sulfamethoxazole. However, *V. cholerae* O1 strains showed resistance to different antibiotics in Asia and Africa at least a decade earlier than the 1990s’ Latin American epidemic. *V. cholerae* El Tor strains isolated in 1977 in Africa were resistant to multiple drugs, including tetracycline (42), and classical strains from Bangladesh isolated during 1982 to 1989 were resistant to ampicillin, furazolidone, and trimethoprim-sulfamethoxazole (22).

**LPS coding region.** The lipopolysaccharide (LPS) of *V. cholerae* is comprised of three main regions: lipid A, the core oligosaccharide (OS), and the O antigen. *V. cholerae* synthesizes the core OS and O antigen using the *wav* and *wb* gene clusters, respectively (43). The *wav* gene cluster (VC0223 to -240) of the Mexican isolates is similar to that of *V. cholerae* N16961, except for CP1035, which is different in seven of the ORFs (Fig. 3). *V. cholerae* CP1035 has a *wav* gene cluster homologous to *V. cholerae* TM11079-80, an environmental strain isolated in Brazil in 1980 (Fig. 3). Interestingly, both strains are phenotypically El Tor, but they lack two major virulence-associated genomic islands, CTXΦ encoding...
CtxAB and *Vibrio* pathogenicity island VPI-1, which contains the genes for biosynthesis of toxin-coregulated pilus (TCP).

**Phylogenetics of the Mexican isolates.** The phylogeny of the *V. cholerae* strains isolated in Mexico was determined by constructing a genome-relatedness neighbor-joining tree using homologous alignment of 905 orthologous protein-coding genes (~897,461 bp) of 124 *V. cholerae* genomes (Fig. 4), which placed El Tor, classical, and nontoxicogenic *V. cholerae* isolates from Mexico into distinct phylogenetic clades. CP1035, a CTX− isolate, was placed into a basal clade with other nontoxicogenic non-O1/O139 isolates from Haiti and O1 isolates from Brazil and Amazonia. The other CTX− isolate, *V. cholerae* CP1037, was phylogenetically placed into an independent node ancestral to all sixth and seventh pandemic isolates. The presence of ancestral isolate in the Latin American region is indicative of greater phylogenetic diversity and succession of indigenous *V. cholerae* populations in that ecosystem. The classical biotype isolate of *V. cholerae* 95412, isolated from Mexico in 1997, was placed into a monophyletic clade with the other sixth pandemic reference *V. cholerae* strain, O395, and RC27. Classical biotype strains are considered to have been out-competed by seventh pandemic *V. cholerae* El Tor strains in the 1980s and have not been isolated in Asia and Africa after 1990.

**FIG 3** O antigen biosynthetic genes of *V. cholerae* O1 strains CP1035, TM11079, and N16961. The wav and wb* gene clusters of CP1035 are homologous to those of TM11079 and different from those of reference El Tor N16961.

**FIG 4** Neighbor-joining trees showing phylogenetic relationships of 124 *V. cholerae* genomes based on 905 orthologs of protein-coding genes (~897,461 bp). The two *V. cholerae* non-O1/O139 strains (HE09 and HE16) isolated from surface water during the 2010 cholera epidemic in Haiti were used as an outgroup of the tree, and bootstrap values are percentages of 1,000 replications. Mexican *V. cholerae* O1 strains are shown in blue, indicating the distribution among five distinct phylogenetic clades. The top node represents the genomes of isolates from Haiti, Bangladesh, Nepal, the United States, Cameroon, South Africa, the Russian Federation, Zimbabwe, and the Dominican Republic obtained between 2005 and 2011.
(22). In contrast, *V. cholerae* classical strains had been isolated in Mexico until 1997, even though *V. cholerae* El Tor strains were dominant at the beginning of the Latin American epidemic and during the years following, indicating the Mexican ecosystem to be a reservoir for the classical biotype of *V. cholerae* (5).

*V. cholerae* strains CP1032 and CP1033 isolated in Mexico were placed into the paraphyletic hybrid El Tor clade along with Mozambique and Matlab variants of *V. cholerae* El Tor, namely, B-33 and MJ-1236, together with *V. cholerae* O139 isolate MO10 (Fig. 4). These isolates also showed close relativeness to 1991 hybrid *V. cholerae* El Tor strain AG8040 isolated from patients in Bangladesh. Phylogenetic analysis of *V. cholerae* hybrid strains isolated in Mexico clearly shows a separation from contemporary *V. cholerae* El Tor and altered El Tor strains from Asia, Africa, and Haiti. The Matlab variant strains, isolated in 1994 in Bangladesh, were the first to have been reported in the literature as “hybrid,” showing classical biotype specific traits in an El Tor genetic background (9). A decade later, genetically similar hybrid variants were isolated in Mozambique during the 2004 cholera outbreak (11, 44). Isolation of *V. cholerae* CP1032 in 1991 in Mexico suggests hybrid El Tor *V. cholerae* was present at the same time in two different continents—i.e., Asia and America. *V. cholerae* CP1030 also belongs to the seventh pandemic clade. However, it clustered tightly into the monophyletic El Tor clade with *V. cholerae* strains isolated in Mexico, Peru, and Brazil during the Latin American epidemics of the 1990s but distant from recent isolates from Bangladesh, India, Nepal, and Thailand. Furthermore, Zambia, Zimbabwe, and Haiti isolates are also separated from CP1030, suggesting a conserved *V. cholerae* O1 clone that carries a truncated CTXφ instead of RS1 in the upstream region of CTXφ, circulating in the Mexican ecosystem during 2004 to 2008. Since 2000, variants of *V. cholerae* O1 El Tor have prevailed in areas of Asia and Africa where cholera is endemic, with *V. cholerae* prototype El Tor strains rarely isolated (45).

**Conclusion.** This study provides important insights into the molecular epidemiology of cholera in Mexico. Overall, the results of our study and previous studies show the existence of genetically diverse *V. cholerae* O1 in Mexico during 1991 to 2008 (5, 7). Considering the global epidemiology of cholera, although the succession of *V. cholerae* O1 in Mexico remains a mystery, our observations clearly do not support the hypothesis of global transmission of cholera from Africa to Latin America, as proposed elsewhere (8). During the 1990s’ Latin American epidemic, Peru was the first country to have been affected by cholera, and a clonal CTXφ *V. cholerae* O1 El Tor strain was found to be the etiological agent, which was present on the Peruvian coast for at least several months prior to the onset of the cholera epidemic (21). Furthermore, CTXφ *V. cholerae* O1 El Tor had been isolated from two patients with diarrhea in Lima, Peru, in 1988 (21, 46) and from sewage in Brazil in 1982 (21, 47). The environmental stimulus for *V. cholerae* (i.e., the increase in the temperature and phytoplankton abundance due to the El Nino phenomenon or changes in salinity and/or nutrient concentrations) may have triggered the existing CTXφ *V. cholerae* O1 El Tor strains to upsurge rapidly during the 1990s in Peru (21). Molecular typing and phylogenetic analysis of 1990s’ Latin American *V. cholerae* O1 isolates have been done in several studies, and no significant correlation was found between isolates from Asia and Latin America (8, 19). Phylogenetic analysis of the isolates shows that cholera in Mexico during 1991 to 2008 was caused by genetically diverse *V. cholerae* O1 strains belonging to distinct phylogenetic clades. Although, Mexican hybrid isolates show close relativeness to one hybrid isolate from Bangladesh, all of which were isolated in 1991, we do not have sufficient metadata to find out the direction of transmission either from Asia to Latin America or vice versa. Additionally, the antibiotic susceptibility patterns and CTX arrangements of the Mexican isolates strongly contradict the notion of a single-source transmission of *V. cholerae* O1 into Mexico from African countries. The lack of the SXT/R391 ICE in the Latin American CTXφ *V. cholerae* isolates is yet another interesting observation, which requires further study, since concurrent Asian and African isolates generally possess SXT/R391 ICE. Therefore, genetic events occurring in *V. cholerae* O1 strains associated with endemic cholera in Mexico are different from those of Asian and African countries (5, 7). Results provided in this study are concordant with those of previous investigations (5, 7, 22) and suggest a likely association of indigenous populations of *V. cholerae* that play a significant role in the dynamics of cholera in Mexico.

**MATERIALS AND METHODS**

**Bacterial strains.** *Vibrio cholerae* O1 strains analyzed in the present study (n = 6) are listed in Table S1 in the supplemental material with the source, location, and year of isolation. *Vibrio cholerae* O1 strains were provided by the Department of Public Health, Faculty of Medicine, National Autonomous University of Mexico (UNAM) and Centro de Investigación Científica y de Educación Superior de Ensenada. The strains were isolated from cholera patients as part of a nationwide cholera surveillance program conducted between 1983 and 2008 in Mexico (5, 7). The bacterial strains were shipped in T1N1 soft agar (1% trypticase, 1% NaCl, 0.7% agar [pH 7.4]), and the identities were confirmed by standard culture methods and biochemical tests, followed by serogroup and biotype determination, as described previously (48, 49).

**Sequencing, assembly, and annotation.** Genomic DNA of six *V. cholerae* strains was subjected to next-generation whole-genome Illumina and hybrid Illumina/454 sequencing and closure strategies, as previously described (11, 14). Libraries were constructed with target insert sizes of 3 kb and paired-end sizes of 100 bp. Hybrid and Illumina sequences were assembled using Celeria and Velvet assemblers, respectively (50) and all chromosomes were manually annotated using the Manatee system (http://manatee.sourceforge.net/).

**Comparative genomics.** Genome-to-genome comparison was performed by using different approaches because the completeness and quality of the nucleotide sequences varied from strain to strain. First, ORFs of a given pair of genomes were identified and reciprocally compared with each other using the BLASTN, BLASTP, and tBLASTx programs (ORF-dependent comparison). Second, a bioinformatic pipeline was constructed to identify homologous regions of a given query ORF. Initially, a segment on the target contig, which is homologous to a query ORF, was identified using the BLASTN program. This potentially homologous region was expanded in both directions by 2,000 bp. Nucleotide sequences of the query ORF and selected target homologous regions were aligned using a pairwise global alignment algorithm, and the resultant matched region in the subject contig was extracted and saved as a homologue (ORF-independent comparison). Orthologues and paralogs were differentiated by reciprocal comparison, as described previously (11).

**Identification and annotation of genomic islands.** We defined genomic islands (GIs) as a continuous array of five or more coding sequences (CDSs) that were discontinuously distributed among genomes of test strains. Correct transfer or insertion of GIs was readily differentiated from a deletion event by comparing the genome-based phylogenetic tree and full matrices showing pairwise detection of orthologous genes between test strains. Identified GIs were designated and annotated using the BLASTP search of its member CDSs against the GenBank NR database, as described elsewhere (11).
Phylogenetics based on genome sequences. Orthologous regions of *V. cholerae* N16961 were identified by comparisons based on similarity and were used to generate phylogenetic trees (14). The set of orthologous regions for each CDS of a reference genome was identified according to nucleotide similarity and aligned using CLUSTALW2. The resultant multiple alignments were concatenated to form genome-scale alignments, which were then used to generate the neighbor-joining phylogenetic trees (51).

Nucleotide sequence accession numbers. Whole-genome sequences of CP1030, CP1032, CP1033, CP1035, CP1037, and 95412 have been deposited in the DDBJ/EMBL/GenBank databases under accession no. ALCC00000000, ALDA00000000, AJRL00000000, AJRM00000000, ALDB00000000, and APFM00000000, respectively.
