Abstract

Starting from the pseudo-$B_0$ gauge solution for marginal deformations in OSFT, we analytically compute the relation between the perturbative deformation parameter $\tilde{\lambda}$ in the solution and the BCFT marginal parameter $\lambda$, up to fifth order, by evaluating the Ellwood invariants. We observe that the microscopic reason why $\tilde{\lambda}$ and $\lambda$ are different is that the OSFT propagator renormalizes contact-term divergences differently from the contour deformation used in BCFT.

1 Introduction and conclusion

In the recent years there has been published overwhelming evidence that the various consistent open string backgrounds (i.e. D-branes) can be described analytically as solitons of open string field theory (OSFT) [1–11].\textsuperscript{1}

A classical [15] yet not fully understood problem in this correspondence is how the D-branes moduli space is described in OSFT. Given an exactly marginal boundary field $j$, there is a corresponding family of OSFT solutions, which can be generically found in powers of a deformation parameter $\tilde{\lambda}$,

$$\Psi_\tilde{\lambda} = \tilde{\lambda}cj(0)\langle 0 \rangle + \sum_{k=2}^{\infty} \tilde{\lambda}^k \Psi_k,$$

where $\Psi_k$ are perturbative contributions obeying the recursive relation

$$Q\Psi_k + \sum_{n=1}^{k-1} \Psi_n \Psi_{k-n} = 0. \quad (1.2)$$

Physically we expect that the deformation parameter $\tilde{\lambda}$, which we used to construct the solution, should be related to the natural parameter $\lambda$ in boundary conformal field theory (BCFT), given by the coefficient in front of the boundary interaction which deforms the original world-sheet action,

$$S_\lambda = S_0 + \lambda \int_{-\infty}^{\infty} dx \: j(x). \quad (1.3)$$

On general grounds, $\tilde{\lambda}$ does not have a gauge invariant meaning, but nonetheless it is useful to understand how $\lambda$ and $\tilde{\lambda}$ are related for a given solution, because this can shed light on the different mechanisms by which a classical solution changes the world-sheet boundary conditions.

Analytic solutions for marginal deformations with nonsingular OPE ($jj \sim \text{reg}$) have been computed to all orders in [2,3]. A different perturbative analytic solution for marginal currents with singular OPE has been constructed in [4] and generalized in [5].\textsuperscript{2} An analytic solution for any self-local (hence exact [18]) marginal deformation has been constructed nonperturbatively in [9]. Conveniently, this solution is directly expressed in terms of the deformation parameter of the underlying BCFT, $\lambda$. In [19] this has been used to explicitly find the relation between the BCFT modulus $\lambda$ and the coefficient of the marginal field in the solution $\langle c\partial cj | \Psi(\lambda) \rangle$. It has been observed that this function of $\lambda$ starts linearly; then it has a local maximum, and finally it approaches zero for large values of $\lambda$. Nontrivial evidence that this behavior may also be present in Siegel gauge\textsuperscript{3} has been given in [20] in

---

\textsuperscript{1} See [12–14] for reviews.

\textsuperscript{2} See also [16,17].

\textsuperscript{3} In Siegel gauge the perturbative coefficient $\tilde{\lambda}$ (1.1) and the coefficient of the marginal field in the solution $\langle c\partial cj | \Psi(\lambda) \rangle$ coincide. This is not
level truncation, but it has not been possible there to establish the validity of the full equations of motion for large BCFT moduli.

In this note we would like to study this problem in another analytic wedge-based example, which is quite close to Siegel gauge. We will analyze the observables of the solution proposed by Schnabl in [2], in the so-called pseudo-$B_0$ gauge

$$\Psi_\lambda = \sum_{k=1}^{\infty} \hat{\lambda}^k \hat{U}_{k+1} \hat{\Psi}_k |0\rangle,$$

(1.4)

$$B_0 \hat{\Psi}_k |0\rangle = 0,$$

(1.5)

for a chiral marginal current $j(z)$ with OPE

$$j(z) j(0) = \frac{1}{z^2} + \text{regular.}$$

(1.6)

Computing the Ellwood invariants and matching them with the BCFT expected answers, gives the following relation:

$$\bar{\lambda} = \bar{\lambda}(\lambda) = \lambda - 3 \log 2 \lambda^3 + 2.38996(7) \lambda^5 + O(\lambda^7).$$

(1.7)

Let us comment on the relation found.

Perhaps the most interesting fact about (1.7) is the origin itself: if the found coefficients of $\lambda^{2n+1}$ are obtained by comparing the Ellwood invariants computed from the solution in powers of $\bar{\lambda}$, with the coefficients of the Ishibashi states obtained from the marginally deformed boundary state expressed in powers of $\lambda$, see Eqs. (4.11)–(4.16). Naively these two quantities reduce to the same world-sheet calculation and therefore one would expect to find perfect match between $\lambda$ and $\bar{\lambda}$, which is evidently not true. This is explained as follows. At order $\lambda^k$, the encountered Ellwood invariants have the structure of OSFT tree-level amplitudes between an on-shell closed string and $k$ on-shell open strings given by the marginal field $cj$, with $\bar{\lambda}$ playing the role of the open string coupling constant. These amplitudes are naively affected by infrared divergences due to the collisions of the marginal fields at zero momentum, which correspond to the propagation of the zero momentum tachyon. The propagator $B_0^{\bar{\lambda}(\lambda)}$ gives a uniquely defined prescription to renormalize these singularities; see Sect. 3. On the other hand, in BCFT, the same contact-term divergences are renormalized by contour deformation [18], so that the renormalized boundary interaction $e^{-\bar{\lambda} \lambda} \delta j |0\rangle$ acquires a topological nature. This difference in the renormalization procedure of contact-term divergences is the ultimate reason why $\lambda$ and $\bar{\lambda}$ are different. Had the self-regularization between currents been regular, we would have found no difference between the two quantities.

We also observe that the growing of the coefficients in (1.7) is in agreement with the findings from other non-perturbative approaches (although in different gauges) such as [19,20], and it suggests that the power series in $\bar{\lambda}$ may have a finite radius of convergence. It would be desirable to improve our calculation to be able to estimate the growing of the higher order coefficients and the nature of the singularity in the complex $\bar{\lambda}$ space. This would be a complementary (perturbative) way of understanding the reason why (in Siegel gauge) the marginal solution breaks down at a critical value of $\lambda$. Indeed, it turns out that our computations in pseudo-$B_0$ gauge can be related to the analogous computations in Siegel gauge, whose direct evaluation is notoriously complicated. Work in this direction is in progress [21].

The paper is organized as follows. In Sect. 2 we review the needed material for constructing the boundary state in BCFT [18] and in OSFT [23]. Then we review the construction of the marginal solution in the pseudo-$B_0$ gauge [2], and we explicitly write it down up to the fifth order. Section 3 describes the regularization procedure implemented by the propagator $B_0^{\bar{\lambda}(\lambda)}$. In Sect. 4 we write down the coefficients of the Ishibashi states in the boundary state in terms of the deformation parameter $\lambda$ using the standard BCFT prescription by Recknagel and Schomerus [18]. Then we compute the same quantities for the OSFT solution in the pseudo-$B_0$ gauge. Finally we compare the coefficients of the Ishibashi states in OSFT and BCFT and we obtain the function $\bar{\lambda} = \bar{\lambda}(\lambda)$ up to fifth order. An appendix contains useful formulas for the correlators encountered.

2 The boundary state and the marginal solution

Let us consider a deformation of a BCFT by a boundary primary operator $j(x)$ of conformal weight one,

$$\delta S_{\text{BCFT}} = \lambda \int j(x) \, dx.$$  

(2.1)

From the OSFT point of view the new theory can be described by a classical solution, a state in the original BCFT

$$\Psi_\lambda = \tilde{\lambda} \Psi_1 + O(\tilde{\lambda}^2),$$

(2.2)

where

$$\Psi_1 = cj(0) |0\rangle = |cj\rangle.$$  

(2.3)

The leading term in $\tilde{\lambda}$ satisfies the linearized equations of motion

$$Q_B \Psi_1 = 0.$$  

(2.4)

If $j$ is exactly marginal, higher orders in $\tilde{\lambda}$ should exist,

$$\Psi_\lambda = \sum_{k=1}^{\infty} \tilde{\lambda}^k \Psi_k,$$  

(2.5)

Footnote 3 continued
genetically true for other perturbative solutions; see for example [5,17]. This is also not true for the solution [2] analyzed in this paper and the relation can be computed, if needed, by the same methods of Sect. 4.
and they can be found by solving the recursive equations of motion

\[ Q_B \Psi_\ell = \sum_{k=1}^{\ell-1} \Psi_k \Psi_{\ell-k}, \]  

(2.6)

with the initial condition (2.3).

Notice that while in BCFT the perturbation is unique, the OSFT solution is not unique because it can be changed by gauge transformations. We can get rid of this gauge redundancy by computing observables. In particular the information on the marginal deformation can be effectively cast in the boundary state.

Boundary states in bosonic string theory can be written as a superposition of Ishibashi states \(|\psi^m\rangle\) [24]

\[ |B_m\rangle = \sum_m n_m |\psi^m\rangle \otimes |B_m\rangle, \]  

(2.7)

where \(|B_m\rangle\) is the universal ghost part. When we deform a given world-sheet theory with an exactly marginal boundary deformation, the boundary state will be deformed to

\[ \delta S_{BCFT} = \lambda \int j(x) \, dx \rightarrow |B(\lambda)\rangle, \]  

(2.8)

with

\[ |B(\lambda)\rangle = [e^{-\lambda \int j(s) \, ds}]_k |B_0\rangle, \]  

(2.9)

where \([\ldots]_k\) means that a regularization is needed (and it will be reviewed later on), and \(|B_0\rangle\) is the boundary state of the starting BCFT.

On the other hand, given an OSFT solution \(\Psi_{\lambda}\), the boundary state will depend on \(\tilde{\lambda}\)

\[ \Psi_{\tilde{\lambda}} \rightarrow |B_{\Psi}(\tilde{\lambda})\rangle. \]  

(2.10)

The two boundary states should be the same by the Ellwood conjecture [25] and this induces a functional relation

\[ \tilde{\lambda} = \tilde{\lambda}(\lambda). \]  

(2.11)

To obtain this relation we can compare the coefficients of the Ishibashi states. From (2.7) it follows that\(^4\)

\[ n^\text{BCFT}_m(\lambda) = \langle \mathcal{V}_m | B(\lambda) \rangle = \langle \mathcal{V}_m | e^{-\lambda \int j(s) \, ds} \rangle_k |B_0\rangle = \left[ e^{-\lambda \int j(s) \, ds} \right]_k \mathcal{V}_m(0, 0) \]  

(2.12)

where \(\mathcal{V}_m\) is the BPZ conjugate of the Virasoro primary \(|\psi^m\rangle\) of the matter so that \(\langle \mathcal{V}_m | \psi^m \rangle = \langle \mathcal{V}_m | \psi^m \rangle = \delta^m_m\) where we used the fact that Ishibashi states have the generic form

\[ |\psi^m\rangle = |\psi^m\rangle + \text{Virasoro descendants}. \]  

(2.13)

The series expansion of the exponential in (2.12) gives rise to contact divergences and one needs to renormalize them properly. In the next section we will review the standard procedure of [18].

The way to compute the \(n_m\) from OSFT was given in [23] by appropriately generalising the Ellwood invariant

\[ n^\text{OSFT}_m(\tilde{\lambda}) = \left\{ \mathcal{V}_m | B_{\Psi}(\tilde{\lambda}) \right\} = 2\pi i (\mathcal{I} | V_m(0, 0) (i, -i) | \Psi_{\tilde{\lambda}} - \Psi_{\tilde{\lambda}}), \]  

(2.14)

where \(\Psi_{\tilde{\lambda}}\) is a tachyon vacuum solution and \(V_m(0, 0) (i, -i)\) is a weight \((0, 0)\) bulk field of the form

\[ V_m(0,0) \equiv c \hat{c} V_m(1,1) = c \hat{c} \gamma_m^{(h_m-h_m)} \otimes \gamma_m^{(1-h_m,1-h_m)}. \]  

(2.15)

As explained in detail in [23], the auxiliary bulk field \(\gamma_m^{(1-h_m,1-h_m)}\) lives in an auxiliary BCFT\(_{aux}\) of \(c = 0\) and has unit one-point function on the disk,

\[ \left\{ \gamma_m^{(1-h_m,1-h_m)}(0,0) \right\}_{\text{Dsk}} = 1. \]  

(2.16)

In a similar way the open string fields entering in (2.14) are lifted to the extended BCFT

\[ \text{BCFT}\_\text{aux} = \text{BCFT}_0 \otimes \text{BCFT}_{aux}. \]  

(2.17)

For the solution we will be dealing with this lifting procedure is trivial and amounts to the substitution \(L_n \rightarrow L_n + L_n^{\text{aux}}\) in the equations that will follow. For this reason we will not distinguish between normal and lifted string fields in the sequel.

As far as the solution itself is concerned, we search for it in the convenient pseudo-\(\mathcal{B}_0\) gauge [2], making the following ansatz:

\[ \Psi_{\tilde{\lambda}} = \sum_{r=1}^{\infty} (\tilde{\lambda})^r U_{r+1}^{*} U_{r+1} \Psi_r |0\rangle, \]  

(2.18)

with the gauge condition

\[ \mathcal{B}_0 \Psi_r |0\rangle = 0, \]  

(2.19)

where \(\mathcal{B}_0\) is the zero mode of the \(b\) ghost in the Sliver frame, obtained from the UHP by the conformal transformation \(z = \frac{\pi}{\lambda} \arctan w\)

\[ \mathcal{B}_0 = \oint \frac{dz}{2\pi i} \, z b(z), \]  

(2.20)

and the operators \(U_r\) are the common exponentials of total Virasoro operators creating the wedge states [27] in the well known way

\[ |r\rangle = U_r^{*} U_r |0\rangle = |0\rangle \ast \ldots \ast |0\rangle. \]  

(2.21)

Solving order by order in \(\tilde{\lambda}\) (2.6) we find

\[ \text{...} \]
\[ O(\lambda^2): \quad Q \Psi_2 = -(cj)^2. \]
The r.h.s. is explicitly given by
\[
(cj)^2 \equiv cj(0)|0\rangle \langle 0| cj(0)|0\rangle \\
= U_s^* U_3 cj \left( \frac{1}{2} \right) cj \left( -\frac{1}{2} \right) |0\rangle, \tag{2.22}
\]
where the \( cj \) insertions are written in the Sliver frame. The solution is therefore
\[
\Psi_2 = U_s^* U_3 \hat{\Psi}_2 |0\rangle \\
= -U_s^* U_3 \frac{B_0}{L_0} cj \left( \frac{1}{2} \right) cj \left( -\frac{1}{2} \right) |0\rangle, \tag{2.23}
\]
where \( L_0 \) is the zero mode of the energy-momentum tensor in the Sliver frame,
\[
L_0 = \oint \frac{dz}{2\pi i} z T(z). \tag{2.24}
\]
Note that inverting \( Q_B \) using \( B_0/L_0 \) is only meaningful if the OPE of \( cj \) with itself does not produce weight zero terms, otherwise we would find a vanishing eigenvalue of \( L_0 \). As is well known this is the first nontrivial condition for \( j \) to generate an exactly marginal deformation.

\[ O(\lambda^3): \quad Q_B \Psi_3 + [cj, \Psi_2] = 0. \]

At the third order the solution \( \Psi_3 \) is written in terms of \( \Psi_2 \). We write the state \([cj, \Psi_2]\) as
\[
[cj, \Psi_2] = \begin{bmatrix} U_s^* U_2 cj(0)|0\rangle, & U_s^* U_3 \hat{\Psi}_2 |0\rangle \end{bmatrix} \\
= U_s^* U_4 \begin{bmatrix} cj(0), & \hat{\Psi}_2 \end{bmatrix}_{(2,3)} |0\rangle, \tag{2.25}
\]
where in the second step we explicitly write the width of the wedge states using the \( U_r \) operators. The inside insertions have to be placed according to (A.2): to lighten a bit the notation we have defined the graded commutator-like symbol \( \llbracket \ldots \rrbracket \) as
\[
\llbracket \psi(x), \phi(y) \rrbracket_{(x,y)} \\
\equiv \psi (x + \frac{s-1}{2}) \phi (y - \frac{r-1}{2}) \\
- (-1)^{\|x\|\|y\|} \phi (y + \frac{r-1}{2}) \psi (x - \frac{s-1}{2}), \tag{2.26}
\]
coming from
\[
\llbracket U_r^* U_s \psi(x)|0\rangle, & U_s^* U_r \phi(y)|0\rangle \rrbracket \]
\[
= U_{r+s-1}^* U_{r+s-1} \llbracket \psi(x), \phi(y) \rrbracket_{(x,y)} |0\rangle. \tag{2.27}
\]
Finally we can write the solution at the third order as
\[
\Psi_3 = U_4^* U_5 \hat{\Psi}_3 |0\rangle \\
= -U_4^* U_5 \frac{B_0}{L_0} \llbracket cj, \hat{\Psi}_2 \rrbracket_{(2,3)} |0\rangle. \tag{2.28}
\]

\[ O(\lambda^4): \quad Q_B \Psi_4 + [cj, \Psi_3] + \Psi_2 = 0. \]

Again,
\[
\Psi_4 = U_s^* U_5 \hat{\Psi}_4 |0\rangle \\
= -U_s^* U_5 \frac{B_0}{L_0} \llbracket U_4^* U_5 \hat{\Psi}_3 |0\rangle \llbracket cj, \hat{\Psi}_2 \rrbracket_{(2,3)} |0\rangle \llbracket \phi, \Psi_3 \rrbracket_{(2,4)} |0\rangle. \tag{2.29}
\]

\[ O(\lambda^5): \quad Q_B \Psi_5 + [cj, \Psi_4] + [\Psi_2, \Psi_3] = 0. \]

We find the fifth order as
\[
\Psi_5 = U_6^* U_6 \hat{\Psi}_5 |0\rangle \\
= -U_6^* U_6 \frac{B_0}{L_0} \llbracket U_4^* U_5 \hat{\Psi}_4 |0\rangle \llbracket \Psi_2, \Psi_3 \rrbracket_{(3,4)} |0\rangle. \tag{2.30}
\]

This procedure can be continued to higher order.\(^5\) Although higher orders can easily be written down, their Ellwood invariants become more and more complicated because they involve a large number of multiple integrals which by themselves need to be properly renormalized, as we will see in the next section.

### 3 Contact-term divergences and the propagator

The computation of the Ellwood invariants for the solution we have just presented involves in general contact divergences due to the definition of the propagator \( B_0/L_0 \). As usual, we start by defining the inverse of \( L_0 \) via the Schwinger representation
\[
\frac{1}{L_0} = \int_0^1 \frac{ds}{s} s L_0, \tag{3.1}
\]
which is well defined for eigenvalues of \( L_0 \) with a strictly positive real part. The operator \( s L_0 \) is the generator of dilatations \( z \mapsto sz \) in the Sliver frame. Its action on a primary field with conformal weight \( h \) in the Sliver frame is

\(^5\) In [2] an all-order expression is written down, by explicitly acting with the \( B_0 \) ghosts, which coincides with our expressions, up to the issue of renormalizing contact-term divergences. We keep the propagators \( B_0/L_0 \) explicit, because they are the origin of the contact-term renormalization we will describe next.
states at the same time, we need a representation of states. Since the star product generates both positive and negative weight however, this integral representation does not work for positive weight |h|, 
\[ \frac{1}{L_0} \langle \varphi_{-|h|} \rangle = \int_0^1 \frac{ds}{s} s^{L_0} \langle \varphi_{-|h|} \rangle 
= \langle \varphi_{-|h|} \rangle \int_0^1 \frac{ds}{s^{1/|h|+1}}, \quad \text{(incorrect)}, \]
we find a divergence, as s approaches zero. But this just reflects that the integral representation (3.1) has been used outside its domain of validity. This can easily be remedied in the following way:
\[ \frac{1}{L_0} \langle \varphi_{-|h|} \rangle = \int_0^1 \frac{ds}{s^{1/|h|}} s^{L_0} \langle \varphi_{-|h|} \rangle \bigg|_{\epsilon=0} = \int_0^1 \frac{ds}{s^{1/|h|}} s^{L_0} \langle \varphi_{-|h|} \rangle \bigg|_{\epsilon=0}. \]  
This prescription amounts to computing the Schwinger integral in its region of convergence by assuming Re(\epsilon) > |h|, and then analytically continuing to \( \epsilon = 0 \)
\[ \frac{1}{L_0} \langle \varphi_{-|h|} \rangle = \int_0^1 \frac{dx}{x^{1/|h|}} x^{L_0} \langle \varphi_{-|h|} \rangle \bigg|_{\epsilon=0} = \int_0^1 \frac{dx}{x^{1/|h|}} x^{L_0} \langle \varphi_{-|h|} \rangle \bigg|_{\epsilon=0} = \frac{1}{\epsilon} \langle \varphi_{-|h|} \rangle \bigg|_{\epsilon=0} = -\frac{1}{|h|} \langle \varphi_{-|h|} \rangle. \]  
This analytic continuation allows one to define \( L_0^{-1} \) on every state we encounter during our computations except on weight zero states which remain as an obstruction, as it should be.\(^7\) Pragmatically, this procedure is equivalent to adding and removing the tachyon contribution from the OPE, for example,
\[ \mathcal{B}_0 \left[ c_j(x) c_j(-x) \right] \rightarrow \mathcal{B}_0 \left[ c_j(x) c_j(-x) + \frac{1}{2x} c \partial c \right]. \]  
and to defining \( 1/L_0 \) on the tachyon as
\[ \frac{1}{L_0} \langle c \partial c \rangle = -\langle c \partial c \rangle. \]  

### 4 Comparing \( \lambda \) and \( \tilde{\lambda} \)

In this section we perturbatively compute the coefficients of the series expansion of \( \tilde{\lambda} = \tilde{\lambda} (\lambda) \)
\[ \tilde{\lambda} = \tilde{\lambda} (\lambda) = \sum_{k=0}^{\infty} b_k \lambda^k, \]  
up to fifth order. On general grounds we expect that \( b_0 = 0 \) and \( b_1 = 1 \), and this will be verified in the next subsections.

The \( B_{BCFT} \) coefficients are computed by equating the coefficients of the Ishibashi states in the boundary state in BCFT and OSFT \[ n_{BCFT}^m (\lambda) = n_{OSFT}^m (\tilde{\lambda}). \]  
In both cases one can expand the above coefficients in power series of the corresponding deformation parameter
\[ n_{BCFT}^m (\lambda) = \sum_{k=0}^{\infty} B_{k,m}^{BCFT} \lambda^k, \quad n_{OSFT}^m (\tilde{\lambda}) = \sum_{k=0}^{\infty} B_{k,m}^{OSFT} \tilde{\lambda}^k. \]  
The \( B_{BCFT} \) coefficients can be found expanding the exponential in (2.12),
\[ B_{k,m}^{BCFT} \equiv \frac{(-1)^k}{k!} 2^{2h_m} \int_{-\infty}^{\infty} ds_1 \ldots \int_{-\infty}^{\infty} ds_k \langle \mathcal{V}_m(i, -i) j(s_1) \ldots j(s_k) \rangle_{UHP} \]  
where the conformal factor \( 2^{2h_m} \) comes from the transformation of \( \mathcal{V}_m \) under the map from the disk to the UHP.

These integrals need a renormalization, discussed by Recknagel and Schomerus [18]: thanks to the self-locality property of the current \( j \), one can modify the path of each integral to be parallel to the real axis but with a positive imaginary part \( \epsilon \), with \( 0 < \epsilon << 1 \),
\[ \int_{-\infty}^{\infty} dx_{k-1} \rightarrow \int_{-\infty}^{\infty+i\epsilon} dx_{k-1}. \]  
In such a way all the contact divergences between the currents are avoided and only the contraction of the currents with the closed string will give contribution. Thanks to this
renormalization the loop operator \( e^{-\lambda \bar{f} j(x) dx} \) becomes a topological defect.

For the sake of simplicity we consider an exactly marginal deformation produced by the operator

\[
j(z) = i \sqrt{2} \partial X(z),
\]

(4.6)
on an initial Neumann boundary condition of a free boson compactified at the self-dual radius \( R = 1(\alpha' = 1) \). This deformation switches on a Wilson line in the compactified direction, which can be detected by a closed string vertex operator carrying winding charge,

\[
\nu_m(z, \bar{z}) = e^{im \bar{X}(z, \bar{z})},
\]

(4.7)
where \( m \) is the winding number (which specifies the closed string index) and \( \bar{X}(z, \bar{z}) = X(z) - \bar{X}(\bar{z}) \) the T-dual field of \( X(z, \bar{z}) \).\(^9\) This closed string state has conformal weight \((m^2, -m)\).

Performing the renormalized integral (4.4), one obtain with this choice of the current and closed string state (see Appendix 1 for conventions and basic correlators),

\[
B_{k,m}^{\text{BCFT}} = \left( -\frac{im \sqrt{2} \pi}{k!} \right)^k,
\]

(4.8)
which can easily be resummed to

\[
n_m^{\text{BCFT}}(\lambda) = e^{-im \sqrt{2} \pi \lambda}.
\]

(4.9)

In the OSFT framework, the analytic computation of coefficients of the Ishibashi state involves the Ellwood invariants and we compute them order by order in \( \lambda \), starting from (2.14), which gives

\[
B_{0,m}^{\text{OSFT}} = -2\pi i \langle \mathcal{I} | V_{m}^{(0,0)}(i, -i) | \Psi_1 \rangle,
\]

\[
B_{1,m}^{\text{OSFT}} = 2\pi i \langle \mathcal{I} | V_{m}^{(0,0)}(i, -i) | \phi j \rangle,
\]

\[
B_{k,m}^{\text{OSFT}} = 2\pi i \langle \mathcal{I} | V_{m}^{(0,0)}(i, -i) | \Psi_k \rangle, \quad k \geq 2.
\]

(4.10)
The relation between \( \lambda \) and \( \tilde{\lambda} \) must be universal, in the sense that it cannot depend on the particular choice of the closed string. In our specific computation we will see that this is the case by verifying that the relation is independent of the winding charge \( m \).

Now rewriting (4.2) using (4.3) and (4.1) gives explicitly

\[
O(\lambda^0)
\]

\[
b_0 \propto B_{0,m}^{\text{OSFT}} = B_{0,m}^{\text{BCFT}} (= 0),
\]

(4.11)

\[
O(\lambda^1)
\]

\[
b_1 = \frac{B_{1,m}^{\text{BCFT}}}{B_{1,m}^{\text{OSFT}}},
\]

(4.12)

\[
O(\lambda^2)
\]

\[
b_2 = \left( \frac{B_{1,m}^{\text{OSFT}}}{B_{1,m}^{\text{BCFT}}} \right)^2 \frac{B_{3,m}^{\text{OSFT}}}{B_{3,m}^{\text{BCFT}}},
\]

(4.13)

\[
O(\lambda^3)
\]

\[
b_3 = \left( \frac{B_{1,m}^{\text{OSFT}}}{B_{1,m}^{\text{BCFT}}} \right)^3 \frac{B_{2,m}^{\text{OSFT}}}{B_{2,m}^{\text{BCFT}}} - \left( \frac{B_{1,m}^{\text{OSFT}}}{B_{1,m}^{\text{BCFT}}} \right)^2 \frac{B_{4,m}^{\text{OSFT}}}{B_{4,m}^{\text{BCFT}}} - \left( \frac{B_{1,m}^{\text{OSFT}}}{B_{1,m}^{\text{BCFT}}} \right)^4 \frac{B_{2,m}^{\text{OSFT}}}{B_{2,m}^{\text{BCFT}}},
\]

(4.14)

\[
O(\lambda^4)
\]

\[
b_4 = \left( \frac{B_{1,m}^{\text{OSFT}}}{B_{1,m}^{\text{BCFT}}} \right)^4 \frac{B_{2,m}^{\text{OSFT}}}{B_{2,m}^{\text{BCFT}}} \frac{B_{3,m}^{\text{OSFT}}}{B_{3,m}^{\text{BCFT}}} - \left( \frac{B_{1,m}^{\text{OSFT}}}{B_{1,m}^{\text{BCFT}}} \right)^6 \frac{B_{4,m}^{\text{OSFT}}}{B_{4,m}^{\text{BCFT}}},
\]

(4.15)

\[
\]
\[ b_5 = \frac{14 (B_{BCFT}^{1,m})^5 (B_{SFT}^{2,m})^4}{(B_{1,m}^{SFT})^9} - 21 \frac{(B_{BCFT}^{1,m})^5 (B_{SFT}^{2,m})^2 B_{3,m}^{SFT}}{(B_{1,m}^{SFT})^8} \]
\[ + \frac{6 (B_{BCFT}^{1,m})^5 B_{2,m}^{BCFT} B_{3,m}^{SFT} + 3 (B_{BCFT}^{1,m})^5 (B_{1,m}^{SFT})^2 - 20 (B_{BCFT}^{1,m})^3 B_{2,m}^{SFT} (B_{1,m}^{SFT})^3}{(B_{1,m}^{SFT})^7} + \frac{20 (B_{BCFT}^{1,m})^3 B_{2,m}^{BCFT} B_{2,m}^{SFT} B_{3,m}^{SFT} - (B_{1,m}^{BCFT})^2 B_{5,m}^{SFT}}{(B_{1,m}^{SFT})^6} \]
\[ - \frac{4 (B_{BCFT}^{1,m})^3 B_{2,m}^{BCFT} B_{3,m}^{SFT} + 6 (B_{BCFT}^{2,m})^2 (B_{1,m}^{SFT})^2 B_{3,m}^{SFT} + 6 B_{BCFT}^{1,m} (B_{1,m}^{SFT})^2 (B_{1,m}^{SFT})^2}{(B_{1,m}^{SFT})^5} \]
\[ - \frac{3 (B_{BCFT}^{1,m})^2 B_{5,m}^{SFT} B_{3,m}^{SFT} - 3 B_{BCFT}^{1,m} (B_{2,m}^{SFT})^2 B_{5,m}^{SFT} - 2 B_{BCFT}^{1,m} B_{2,m}^{SFT} B_{2,m}^{BCFT} B_{3,m}^{SFT} + B_{5,m}^{BCFT}}{(B_{1,m}^{SFT})^4} \] (4.16)

4.1 Zeroth order

As a starting consistency check, the zeroth order of the expansion of the coefficients of the Ishibashi states in OSFT is
\[ B_{0,m}^{SFT} = -2 \pi i \langle \mathcal{I} | V_m^{(0,0)}(i, -i) | \Psi_{TV} \rangle, \] (4.17)
where, as explained in [23], the tachyon vacuum contribution can be replaced with \( \Psi_{TV} \to \frac{2}{\pi} e(0) | 0 \rangle \). The amplitude then becomes\(^{10} \)
\[ B_{0,m}^{SFT} = -4i \langle \mathcal{I} | V_m(i, -i) c(0) | 0 \rangle \]
\[ = -4i \langle \mathcal{I} | V_m(i, -i) \mathcal{F}_T \circ c(0) \rangle_{\text{UHP}}, \] (4.18)
where we used the conformal map defining the identity string field \( \mathcal{F}_T(z) = \frac{2z}{1-z} \). Then
\[ B_{0,m}^{SFT} = -2i \langle \mathcal{I} | c(i) c(-i) c(0) \rangle_{\text{UHP}} \langle V_m(i, -i) \rangle_{\text{UHP}} \]
\[ \times \left( \mathcal{V}_{\text{aux}}^{(1-h_m, 1-h_m)}(i, -i) \right)_{\text{UHP}} \]
\[ = -2i (2i) 2^{-2h_m} 2^{2(2h_m-1)} = 1. \] (4.19)
Consistently we find
\[ B_{0,m}^{SFT} = B_{0,m}^{BCFT} = 1, \] (4.20)
which confirms that
\[ b_0 = 0. \] (4.21)

4.2 First order

As an extra starting check, let us look at the first order, where we have to compute
\[ B_{1,m}^{SFT} = 2\pi i \langle \mathcal{I} | V_m(i, -i) c(j) \rangle \]
\[ = 2\pi i \langle \mathcal{I} | V_m(i \infty, -i \infty) c(j(0)) c_1 \rangle, \] (4.22)
where in the last step we wrote the correlator on a cylinder of width one \( C_1 \), without any conformal factor because the conformal weight of all the insertions is zero.

Acting with the map
\[ z \to e^{2\pi i z}, \] (4.23)
this two-point function on the cylinder becomes the two-point function on the disk \( D \),
\[ B_{1,m}^{SFT} = 2\pi i \langle \mathcal{I} | V_m(0, 0) c(j(1)) \rangle_{D} \]
\[ = 2\pi i \langle c\bar{c}(0) c(1) \rangle_{D} \langle \mathcal{V}_m(0, 0) j(1) \rangle_{D} \]
\[ \times \left( \mathcal{V}_{\text{aux}}^{(1-h_m, 1-h_m)}(0, 0) \right)_{D} \]
\[ = 2\pi i \langle \mathcal{V}_m(0, 0) j(1) \rangle_{D} = -i \pi m \sqrt{2}, \] (4.24)
which equals the amplitude computed from BCFT (4.8),
\[ B_{1,m}^{BCFT} = B_{1,m}^{SFT}, \] (4.25)
and so the corresponding coefficient in the \( \tilde{\lambda} / \lambda \) relation is
\[ b_1 = 1. \] (4.26)

4.3 Second order

At second order the Ellwood invariant contains one \( B_0 / L_0 \) propagator inside \( \Psi_2 \).
Using the Wick theorem (which is reviewed in Appendix A) and in particular (A.17) we obtain

\[
B_{2,m}^{\text{SFT}} = - 4\pi i \int_0^1 ds \ s^\epsilon \ \times \left( c(i\infty)c(-i\infty)c(s) \ V_m(i\infty) \ V_{am}^{(1-h_m,1-h_m)}(i\infty) \right)_{C_2} \\
\times \left\{ \left( j(x_2)j(y_2) \right)_{C_2} - m^2 \ \left( \left( \tilde{X}(i\infty)j(0) \right)_{C_2} \right)^2 \right\},
\]

(4.33)

which using (A.13), (A.15) and (A.18) gives

\[
B_{2,m}^{\text{SFT}} = 4 \int_0^1 ds \ s^\epsilon \ \frac{\pi^2}{8} \ \csc^2(\pi s) - m^2 \ \frac{\pi^2}{2},
\]

(4.34)

where the \( \epsilon \) prescription acts only on the first term because it is the only one which is divergent. This gives

\[
\int_0^1 ds \ s^\epsilon \ \frac{\pi^2}{2} \ \left( \csc^2(\pi s) - \frac{1}{\pi^2 s^2} \right) = \int_0^1 ds \ s^\epsilon \ \frac{1}{\pi^2 s^2} \bigg|_{\epsilon=0} = \frac{2}{\pi^2} + \frac{2^{1-\epsilon}}{\pi^2(\epsilon-1)} \bigg|_{\epsilon=0} = 0;
\]

(4.35)

here we have used our analytic continuation which, as explained in Sect. 3, amounts to computing the integral in the region of the \( \epsilon \)-complex plane where it converges (Re \( \epsilon > 1 \)) and then analytically continue to \( \epsilon \to 0 \). In doing this we have also took the freedom of ignoring convergent terms proportional to \( \epsilon \) since we are only interested in the \( \epsilon \to 0 \) limit.

Computing also the other convergent integral, we obtain again a perfect match with the BCFT results,

\[
B_{2,m}^{\text{SFT}} = - m^2 \ \pi^2 = B_{2,m}^{\text{BCFT}},
\]

(4.36)

which leads to

\[
b_2 = 0.
\]

(4.37)

4.4 Third order

At this level the amplitude we have to compute is

\[
B_{3,m}^{\text{SFT}} = 2\pi i \ \langle \mathcal{I} | V_m(i, -i) | \Psi_3 \rangle \\
= 2\pi i \left( V_m(i\infty, -i\infty) \Psi_3 \right)_{C_3},
\]

(4.38)

where \( \Psi_3 \) is defined in (2.28). This amplitude is depicted in Fig. 2.
Explicitly we find
\[
\Psi_3 = U_A U_4 \frac{B_0}{C_0} \left[ \langle cj(0)|0 \rangle, \frac{B_0}{C_0} cj \left( \frac{1}{2} \right) cj \left( -\frac{1}{2} \right) |0 \rangle \right] \\
= U_A U_4 \int_0^1 dy y^{\epsilon_2+1} \int_0^1 dt \frac{t}{2} \epsilon_1 \times \left\{ cj(y) j \left( y \left( \frac{1}{2} - \frac{1}{2} \right) \right) j \left( y \left( -\frac{1}{2} + \frac{1}{2} \right) \right) + j(y) j \left( y \left( \frac{1}{2} - \frac{1}{2} \right) \right) cj(y) \right. \\
+ j(y) \left[ j \left( y \left( \frac{1}{2} - \frac{1}{2} \right) \right) cj(y) \right] + cj(y) j \left( y \left( -\frac{1}{2} + \frac{1}{2} \right) \right) \right\} \\
\times j(-y) \bigg|_{\epsilon_1=0} \bigg|_{\epsilon_2=0}.
\]
(4.39)

where \( \epsilon_1 \) is the regulator for the most internal propagator (the one inside the lower order contribution \( \Psi_2 (2.23) \)) and \( \epsilon_2 \) is the regulator for the external propagator. From the perturbative construction of the solution, it is clear that \( \epsilon_1 \) should be analytically continued to zero before \( \epsilon_2 \). Using the symmetries of the correlator in the matter and ghost sector and renaming \( t/2 \rightarrow t \), the whole Ellwood invariant reduces to
\[
B^{\text{EPT}}_{3,m} = 12 \pi i \int_0^1 dy y^{\epsilon_2+1} \int_0^1 dt \frac{t}{2} \epsilon_1 \left( V_m(i\infty) cj \left( \frac{3}{2} y \right) j \left( \frac{1}{2} y \right) j \left( -\frac{1}{2} y \right) \right)_{C_3}.
\]
(4.40)

It is useful to change variable with \( x = \frac{3}{2} y \) and \( s = ty = \frac{3}{2} xt \) so as to rewrite the integral as
\[
B^{\text{EPT}}_{3,m} = 8 \pi i \int_0^\frac{3}{2} dx x^{\epsilon_2-\epsilon_1} \times \int_0^\frac{3}{2} ds s^{\epsilon_1} \left( V_m(i\infty) cj(x) j(s) j(-s) \right)_{C_3}.
\]
(4.41)

Now we apply the Wick theorem (see (A.17) of Appendix A),
\[
B^{\text{EPT}}_{3,m} = 8 \pi i \left( \langle C_0 \right) \int_0^\frac{3}{2} dx x^{\epsilon_2-\epsilon_1} \int_0^\frac{3}{2} ds s^{\epsilon_1} \\
\times \left\{ \text{im} \left( X(i\infty) j(0) \right) \right\}_{C_3} \left( j(s) j(-s) \right)_{C_3} \\
+ \left( j(x) j(s) \right)_{C_3} \left( j(x) j(-s) \right)_{C_3}
\right\} (4.42)
\]
and using the correlators (A.15) and (A.18), we end up with the following integral:
\[
B^{\text{EPT}}_{3,m} = -12 \int_0^\frac{3}{2} dx x^{\epsilon_2-\epsilon_1} \int_0^\frac{3}{2} ds s^{\epsilon_1} \\
\times \left\{ \text{im} \left( \frac{\pi \sqrt{2}}{3} \right) \left( j(s) j(-s) \right)_{C_3} \\
+ \left( j(x) j(s) \right)_{C_3} \left( j(x) j(-s) \right)_{C_3}
\right\} (4.43)
\]
The first integral contains a divergence in \( j(s) j(-s) \) when \( s \) approaches zero. Explicitly using (A.13) this part of the amplitude is given by
\[
\int_0^\frac{3}{2} dx x^{\epsilon_2-\epsilon_1} \int_0^\frac{3}{2} ds s^{\epsilon_1} \left[ \csc^2 \left( \frac{2\pi}{3} s \right) \right]_{C_3} \\
+ \left( \frac{\pi}{3} (x+s) \right) + \csc^2 \left( \frac{\pi}{3} (x-s) \right)
\right\}_{\epsilon_1=0} \bigg|_{\epsilon_2=0} = \frac{3}{2 \pi} \int_0^\frac{3}{2} dx x^{\epsilon_2} \tan \left( \frac{2\pi}{9} x \right) = \frac{27}{4 \pi^2} \log 2.
\]
Notice that the integral in \( x \) is convergent which tells us that we could have avoided the \( \epsilon_2 \) regulator. This is because the external propagator acts on a state which is in the fusion of three marginal operators and therefore it cannot contain the tachyon in its level expansion. We have
\[
B^{\text{EPT}}_{3,m} = \frac{2\sqrt{2}}{3!} m^3 \pi^3 - 3i \sqrt{2} m \pi \log 2
\]
(4.45)
\[
= B^{\text{EPT}}_{3,m} + (3 \log 2) B^{\text{EPT}}_{1,m}.
\]
Summarizing: from the BCFT side we found that the third order is proportional to $m^3$ (4.8) and there are no other terms. Instead, in the OSFT computation, at the third order we still get the same BCFT number proportional to $m^3$ but in addition to it there is another contribution coming from the peculiar renormalization implicitly defined by the propagator $B_0/L_0$. This is the first time that there appears a discrepancy between the two approaches. As a consequence the third order coefficient in the $\hat{\lambda}(\hat{\lambda})$ equation (4.1) is

\begin{equation}
\begin{aligned}
b_3 &= -3 \log 2. \\
\end{aligned}
\end{equation}

4.5 Fourth order

The fourth order Ellwood invariant is given by

\begin{equation}
\begin{aligned}
B^{\text{OSFT}}_{4,m} &= 2\pi i \langle \mathcal{I} | V_m(i, -i) | \Psi_4 \rangle \\
&= 2\pi i \left( V_m(i\infty, -i\infty) \hat{\Psi}_4 \right)_{C_4} ; \\
\end{aligned}
\end{equation}

there are two contributions coming from the $\Psi_{\hat{\lambda}}$ solution (2.29)

\begin{equation}
\begin{aligned}
\hat{\Psi}_4|0\rangle &= \frac{B_0}{L_0} \left( \left\{ \hat{c}_j(0), \hat{B}_0 \right\} \left[ \hat{c}_j(0), \hat{\Psi}_2 \right]_{(2,3)} \right)_{(2,4)} \\
&\quad - \frac{1}{2} \left[ \hat{\Psi}_2, \hat{\Psi}_2 \right]_{(3,3)} |0\rangle.
\end{aligned}
\end{equation}

The Ellwood invariant at this order is given by

\begin{equation}
\begin{aligned}
B^{\text{OSFT}}_{4,m} &= 2\pi i \left( V_m(i\infty, -i\infty) \hat{B}_0 \left[ \hat{c}_j(0), \hat{B}_0 \right] \left[ \hat{c}_j(0), \hat{\Psi}_2 \right]_{(2,3)} \right)_{(2,4)} \\
&\quad - \frac{1}{2} \left( V_m(i\infty, -i\infty) \hat{B}_0 \left[ \hat{\Psi}_2, \hat{\Psi}_2 \right]_{(3,3)} \right)_{(4)} \\
&= 2\pi i \left( V_m \hat{A}_{2,4} \right)_{C_4} - \left( V_m \hat{A}_{3,3} \right)_{C_4}.
\end{aligned}
\end{equation}

First term $\left( V_m \hat{A}_{2,4} \right)$

In the first term, as before, we need to compute the commutator of the insertions and apply the propagators,

\begin{equation}
\hat{A}_{2,4}(0) = U^*_z U_5 \frac{B_0}{L_0} \left[ \hat{c}_j(0), \hat{B}_0 \right] \left[ \hat{c}_j(0), \hat{\Psi}_2 \right]_{(3,3)} |0\rangle.
\end{equation}

The corresponding amplitude is depicted in Fig. 3.

\begin{equation}
\begin{aligned}
V_m \left\{ \{z\} \epsilon_3, \{y\} \epsilon_2, \{2t\} \epsilon_1 \right\} c_j
\end{aligned}
\end{equation}

Fig. 3 First diagram $\left( V_m \hat{A}_{2,4} \right)$. The first two legs of $c_j$ from the left are to be understood as commutators. The $z$, $y$ and $2t$ variables are the Schwinger parameters (taking value in the interval $[0, 1]$). The integration variable $s$ in (4.51) is related to the Schwinger parameters as $s = ty$

Applying the two propagators, the amplitude takes the form

\begin{equation}
\begin{aligned}
\left( V_m \hat{A}_{2,4} \right)_{C_4} &= -3 \int_0^1 dz \epsilon^{2+\epsilon_3} \int_0^1 dy \epsilon^{2-\epsilon_1} \int_0^{\tilde{\epsilon}} ds \epsilon_{\epsilon_1} \left( V_m(i\infty) \right) \\
&\quad \times \left\{ j (\frac{1}{2} z) j (z (y - \frac{1}{2})) j (z (s - \frac{1}{2} y - \frac{1}{2})) \right. \\
&\quad \times j (z (s - \frac{1}{2} y - \frac{1}{2})) \times c (\frac{1}{2} z) + c (z (y - \frac{1}{2})) \\
&\quad \left. + c (z (s - \frac{1}{2} y - \frac{1}{2})) + c (z (-s - \frac{1}{2} y - \frac{1}{2})) \right. \\
&\quad \times j (\frac{1}{2} z) j (z (-y - \frac{1}{2})) j (z (s + \frac{1}{2} y - \frac{1}{2})) \\
&\quad \times j (z (-s + \frac{1}{2} y - \frac{1}{2})) \times c (\frac{1}{2} z) + c (z (-y - \frac{1}{2})) \\
&\quad + c (z (s + \frac{1}{2} y - \frac{1}{2})) \\
&\quad \left. + c (z (-s + \frac{1}{2} y - \frac{1}{2})) \right\} \left\{ \left( V_m \hat{A}_{3,3} \right)_{C_4} \right\}_{\epsilon_{\epsilon_1}=0} |_{\epsilon_1=0} |_{\epsilon_3=0}.
\end{aligned}
\end{equation}

Using the symmetries of the problem translating the correlators $\xi \rightarrow \xi + \frac{\pi}{4}$ and changing variables $w = sz$ and $x = yz$, the amplitude simplifies to

\begin{equation}
\begin{aligned}
\left( V_m \hat{A}_{2,4} \right)_{C_4} &= -6 \int_0^2 dz \epsilon^{3+\epsilon_3+\epsilon_1} \int_0^{\tilde{\epsilon}} dx \int_{\tilde{\epsilon}}^{\tilde{\epsilon}} dw \epsilon_{\epsilon_1} \\
&\quad \times \left\{ (V_m(i\infty) j(z) j(x) j(w - \frac{1}{2}) j(-w - \frac{1}{2}))_{C_4} \\
&\quad + (V_m(i\infty) j(z) j(w + \frac{1}{2}) j(-w + \frac{1}{2}) j(-x))_{C_4} \right\}.
\end{aligned}
\end{equation}

Second term $\left( V_m \hat{A}_{3,3} \right)$

The second term is the Ellwood invariant of $\hat{A}_{3,3}$,

\begin{equation}
\hat{A}_{3,3}(0) = \frac{1}{2} U^*_z U_5 \frac{B_0}{L_0} \left[ \hat{\Psi}_2, \hat{\Psi}_2 \right]_{(3,3)} |0\rangle,
\end{equation}

and it is depicted in Fig. 4.
Explicitly we have to compute the star product of two $\Psi_2$ and then act with a propagator $B_0/L_0$:

\[
\begin{align*}
\{ V_m, \hat{A}_{3,3} \}_{C_4} &= 
\int_0^1 \frac{dz}{z} \int_0^1 \frac{dt}{t} \int_0^1 \frac{ds}{s} \cdot 
\times 2 \left\{ V_m(i\infty) j(z(t+1)) j(z(-t+1)) + j(z(s-1)) j(z(-s-1)) + c(z(t+1)) + c(z(-t+1)) + c(z(s-1)) + c(z(-s-1)) \right\} \bigg|_{\epsilon_1, \epsilon_2 = 0} \bigg|_{\epsilon_3 = 0}.
\end{align*}
\]

Again the four different insertions of the ghosts contribute in the same way, and therefore

\[
\begin{align*}
\{ V_m, \hat{A}_{3,3} \}_{C_4} &= 8 \int_0^1 \frac{dz}{z} \int_0^1 \frac{dt}{t} \int_0^1 \frac{ds}{s} \cdot 
\times \left\{ V_m(i\infty) c j(z(t+1)) j(z(-t+1)) + j(z(s-1)) j(z(-s-1)) \right\} \bigg|_{C_4}.
\end{align*}
\]

With the change of variable $x = \frac{z}{t}$ and $y = \frac{z}{s}$,

\[
\begin{align*}
\{ V_m, \hat{A}_{3,3} \}_{C_4} &= 8 \int_0^1 \frac{dz}{z} \int_0^1 \frac{dt}{t} \int_0^1 \frac{ds}{s} \cdot 
\times \left\{ V_m(i\infty) c j(z+x) \right\} \bigg|_{C_4} \bigg|_{\epsilon_1, \epsilon_2 = 0} \bigg|_{\epsilon_3 = 0}.
\end{align*}
\]

**Complete $B_{4,m}^{SFT}$**

The complete term at this order is given by summing the two integrals (4.52) and (4.56),

\[
B_{4,m}^{SFT} = -12\pi i \int_0^1 \frac{dz}{z} \int_0^1 \frac{dt}{t} \int_0^1 \frac{ds}{s} \cdot 
\times \left\{ V_m(i\infty) j(z) j(w - \frac{z}{2}) j(\frac{z}{2}) \right\}_{C_4}
+ \left\{ V_m(i\infty) j(z) j(w + \frac{z}{2}) j(\frac{z}{2}) \right\}_{C_4}
- 16\pi i \int_0^1 \frac{dz}{z} \int_0^1 \frac{dx}{x} \int_0^1 \frac{dy}{y} \cdot 
\times \left\{ V_m(i\infty) c j(z+x) \right\} \bigg|_{C_4} \bigg|_{\epsilon_1, \epsilon_2 = 0} \bigg|_{\epsilon_3 = 0}.
\]

As in the previous order $\lambda^3$, here also we have contribution from three different powers of the winding number $m$ coming from the different contractions in Wick theorem (A.17). This means that we can write $B_{4,m}^{SFT}$ in terms of the $B_{k,m}^{SFT} \sim m^k$,

\[
B_{4,m}^{SFT} = a_0 B_{0,m}^{SFT} + a_2 B_{2,m}^{SFT} + a_4 B_{4,m}^{SFT}.
\]

From this consideration (setting to zero all the regulators as they are not important here) we find that

\[
\begin{align*}
a_0 B_{0,m}^{SFT} &= \frac{6}{8} m^4 \pi^4 \int_0^1 \frac{dz}{z} \int_0^1 \frac{dx}{x} \int_0^1 \frac{dw}{w} \cdot 
\times \left\{ 2 \csc^2 \left( \frac{\pi}{4} \left( \frac{w}{2} - \frac{3}{2} \right) \right) + 2 \csc^2 \left( \frac{\pi}{4} \left( \frac{w}{2} + \frac{3}{2} \right) \right) \right\} \bigg|_{\epsilon_1 = 0} \bigg|_{\epsilon_2 = 0} \bigg|_{\epsilon_3 = 0},
\end{align*}
\]

\[
\begin{align*}
a_2 B_{2,m}^{SFT} &= -\frac{3}{16} m^2 \pi^4 \int_0^1 \frac{dz}{z} \int_0^1 \frac{dx}{x} \int_0^1 \frac{dw}{w} \cdot 
\times \left\{ 2 \csc^2 \left( \frac{\pi}{4} \left( \frac{w}{2} + \frac{3}{2} \right) \right) + 2 \csc^2 \left( \frac{\pi}{4} \left( \frac{w}{2} - \frac{3}{2} \right) \right) \right\} \bigg|_{\epsilon_1 = 0} \bigg|_{\epsilon_2 = 0} \bigg|_{\epsilon_3 = 0}.
\end{align*}
\]
\[ a_0 B_{0,m}^{\text{SFT}} = -\frac{3}{32} \pi^4 \int_0^\infty \frac{dz}{z^3 + e_2 - 2e_1} \int_0^\infty dx \times \int_0^\infty dw \, w^{e_1} \left\{ \csc^2 \left( \frac{\pi}{2} w \right) \csc^2 \left( \frac{\pi}{4} (z + x) \right) + \csc^2 \left( \frac{\pi}{4} (w + \frac{3}{2} x) \right) \csc^2 \left( \frac{\pi}{4} (z - x) \right) + \csc^2 \left( \frac{\pi}{4} (w + 3 x) \right) \csc^2 \left( \frac{\pi}{4} (z - 3 x) \right) + \csc^2 \left( \frac{\pi}{4} (w - \frac{3}{2} x) \right) \csc^2 \left( \frac{\pi}{4} (z + x) \right) + \csc^2 \left( \frac{\pi}{4} (w - 3 x) \right) \csc^2 \left( \frac{\pi}{4} (z - 3 x) \right) + \csc^2 \left( \frac{\pi}{4} (w + x) \right) \csc^2 \left( \frac{\pi}{4} (z + 3 x) \right) \right\} \mid_{\epsilon_1 = 0} \mid_{\epsilon_2 = 0} \mid_{\epsilon_3 = 0} \]
where the Schwinger parameters $t_1, t_2, t_3, t_4$ are related to the integration variables as

\[
T = t_4, \\
X = t_4 t_3, \\
Y = t_4 t_3 t_2, \\
Z = t_4 t_3 t_2 t_1.
\]

**Second term** $\langle V_m \hat{A}_{3,4} \rangle$

The state here is

\[
\hat{A}_{3,4}(0) = U_m^6 U_0 \frac{B_0}{\Lambda_0} \left[ [\hat{\Psi}_2, \frac{B_0}{\Lambda_0} \left[ c j(0), \hat{\Psi}_2 \right]_{(3),3} \right]_{(3,4)} |0\rangle,
\]

and its Ellwood invariant is (Fig. 6)

\[
2\pi i \left\langle V_m \hat{A}_{3,4} \right\rangle_{C_5} = -24\pi i \int_0^{\frac{t}{2}} dT T^{e_4-e_3-e_2} \times \int_0^{\frac{T}{2}} dX X^{e_3-e_2} \int_0^{\frac{X}{2}} dY Y^{e_2} \int_0^{\frac{Y}{2}} dZ Z^{e_1} \times \left\{ \langle V_m(i \infty) c j(T + Z) j(T - Z) j(X) \times j(Y - \frac{X}{2}) j(-Y - \frac{X}{2}) \rangle_{C_5} + \langle V_m(i \infty) c j(T + Z) j(T - Z) j(Y + \frac{X}{2}) \times j(-Y + \frac{X}{2}) j(-X) \rangle_{C_5} \right\}_{\epsilon_1=0, \epsilon_2=0, \epsilon_3=0, \epsilon_4=0},
\]

where the Schwinger parameters are related to the integration variables as

\[
T = t_4, \\
X = t_4 t_3, \\
Y = t_4 t_3 t_2, \\
Z = t_4 t_3 t_1.
\]

**Third term** $\langle V_m \hat{A}_{2,5} \rangle$

The last term involves the state

\[
\hat{A}_{2,5}^{3,3}(0) = \frac{1}{2} U_m^5 U_5 \frac{B_0}{\Lambda_0} \left[ [\hat{\Psi}_2, \hat{\Psi}_2]_{(3,3)} \right]_{(2,3)} |0\rangle,
\]

and it becomes (Fig. 7)

\[
2\pi i \left\langle V_m \hat{A}_{2,5}^{3,3} \right\rangle_{C_5} = 32\pi i \int_0^{\frac{t}{2}} dT T^{e_4-e_3} \times \int_0^{\frac{T}{2}} dX X^{e_3-e_2-e_1} \int_0^{\frac{X}{2}} dY Y^{e_2} \int_0^{\frac{Y}{2}} dZ Z^{e_1} \times \left\{ \langle V_m(i \infty) c j(T) j(X + Y) j(X - Y) \times j(Z - X) j(-Z - X) \rangle_{C_5} + \langle V_m(i \infty) c j(X + Y) j(X - Y) j(Z - X) \times j(-Z - X) j(-T) \rangle_{C_5} \right\}_{\epsilon_1=0, \epsilon_2=0, \epsilon_3=0, \epsilon_4=0},
\]

where the Schwinger parameters are related to the integration variables as

\[
T = t_4, \\
X = t_4 t_3, \\
Y = t_4 t_3 t_2, \\
Z = t_4 t_3 t_1.
\]

**Complete $B_{S,m}^{\text{BCFT}}$**

Now we have to compute the three Ellwood invariants as we have done in previous examples. Again the total Ellwood invariant can be expanded in terms of the first, third and fifth power of the winding number,

\[
B_{S,m}^{\text{BCFT}} = a_1 B_{1,m}^{\text{BCFT}} + a_3 B_{3,m}^{\text{BCFT}} + a_5 B_5^{\text{BCFT}}.
\]
The $a_5$ coefficient is easily computed:

$$a_5 B_{BCFT}^5 = -480 \frac{(i m)^5}{5!} \left( (X(i \infty) j(0))_c^5 \right) \times \int_0^\frac{2}{5} dT \int_0^\frac{T}{5} dX \int_0^{2X} dY \int_0^\frac{Y}{5} dZ$$

$$- 300 \frac{(i m)^5}{5!} \left( (X(i \infty) j(0))_c^5 \right) \times \int_0^\frac{2}{5} dT \int_0^\frac{T}{5} dX \int_0^{X} dY \int_0^\frac{Y}{5} dZ$$

$$- 80 \frac{(i m)^5}{5!} \left( (X(i \infty) j(0))_c^5 \right) \times \int_0^\frac{2}{5} dT \int_0^\frac{T}{5} dX \int_0^{X} dY \int_0^\frac{Y}{5} dZ$$

$$= i \frac{4\sqrt{2}}{5!} \pi^5 m^5 = B_{BCFT}^5,$$

which gives the usual exact match with the BCFT results. As far as $a_3$ is concerned the computation follows closely the fourth order (with one more integral) and everything can be analytically done giving the result

$$a_3 = 9 \log 2.$$  

(4.77)

This is precisely the number needed to ensure that $b_5$ is $m$-independent (4.16) so this is a consistency check.

Let us now address the $a_1$ coefficient, which is determined by the $O(m)$ winding number contribution in (4.75). This is generated by the term from the Wick theorem with the maximal number of contractions between the $j$ and computing the four dimensional integrals (coming from the three diagrams) analytically is not possible. Therefore we proceed analytically as far as we can and then we resort to numerics. The $Y$ and $Z$ integrals can be analytically computed in all of the three diagrams, including the subtraction of the tachyon divergence.

Rescaling the $X$ variable in the first diagram $X \rightarrow 2X$, the $O(m)$ contribution $E_i$ from each diagram is reduced to an expression of the form

$$a_1 B_{BCFT}^1 = E_1 + E_2 + E_3, \quad O(m)$$

$$E_i = \int_0^\frac{2}{5} dT \int_0^{X_{\epsilon_3}} dX \int_0^{X_{\epsilon_4}} f_i(T, X) \bigg|_{\epsilon_3=0, \epsilon_4=0}, \quad i = 1, 2, 3,$$

(4.78)

where the function $f_i$ are known analytically. To renormalize the tachyon divergence in the $X$ integration we explicitly subtract the second order pole in $X$ from the function $f_i$ in the following way:

$$F_i(T) = \int_0^{\frac{2}{5} T} dX X^{\epsilon_3} f_i(T, X) \bigg|_{\epsilon_3=0}$$

$$= \int_0^{\frac{2}{5} T} dX \left( f_i(T, X) - \frac{(f_i)_{\epsilon=2}}{X^2} \right)$$

$$+ \int_0^{\frac{2}{5} T} dX X^{\epsilon_3} \frac{(f_i)_{\epsilon=2}}{X^2} \bigg|_{\epsilon_3=0}. \quad (4.79)$$

$$\odot$$ Springer
Fig. 9 In a we show the three residues of the simple poles corresponding to the three diagrams. In b the sum of the three functions $F_i(t)$ is shown to be finite in $T = 0$.

It turns out that the coefficient of the $1/X^2$ pole, which in the above formula is indicated as $(f_i)_{-2}$, is $T$ independent.

This treatment leaves us with three numerical functions of $T$, which have to be integrated in the interval $[0, \frac{\pi}{2}]$. Surprisingly each of these functions shows a nonvanishing $1/T$ pole, as shown in Fig. 8,

$$F_i(T) = \frac{p_i}{T} + \tilde{F}_i(T),$$

with $\tilde{F}_i$ finite in $T = 0$. We explicitly find

$$p_1 = -62.10989(8),$$

$$p_2 = -2.45519(8),$$

$$p_3 = 64.56508(9).$$

These poles are potentially problematic, and it is reassuring that the sum of them vanishes,

$$p_1 + p_2 + p_3 = 0;$$

see also Fig. 9. This is an important consistency check, because a $1/T$ pole would be an obstruction to the existence of the solution at the fifth order. Numerically computing the
integral over $T$ finally gives

$$a_1 = 10.58226(7).$$

(4.83)

To conclude the total contribution to fifth order is given by

$$B_{5,m}^{\text{BCFT}} = B_5^{\text{SFT}} + (9 \log 2) \ B_3^{\text{BCFT}} + 10.58226(7) \ B_5^{\text{BCFT}},$$

(4.84)

which corresponds to (4.1)

$$b_5 = 2.38996(7).$$

(4.85)

Acknowledgements We would like to thank Ted Erler, Marialuisa Frau and Martin Schnabl for discussions. We especially thank Matej Kudrna for discussions and for sharing interesting Siegel gauge results in level truncation. PVL warmly thanks Edoardo Lauria for useful discussions and comments. CM thanks Nathan Berkovits and the other organizers of the VIII workshop String Field Theory and Related Aspects, where some of our preliminary results were reported. The research of CM is funded by a Rita Levi Montalcini grant from the Italian MIUR. This work is partially supported by the Compagnia di San Paolo contract MAST: Modern Applications of String Theory TO-Call3-2012-0088 and by the MIUR PRIN Contract 2015MP2CX4 Non-perturbative Aspects Of Gauge Theories And Strings.

Appendix A: Conventions and correlators

Witten’s star product
The Witten star product is best understood in the Sliver frame (with coordinate $z$), which is related to the UHP (with coordinate $w$) by the map

$$z = \frac{2}{\pi} \arctan w.$$ (A.1)

In this frame the star product of wedge states with insertions is given by

$$\left( U^*_r U_t \Phi_1(x_1) \ldots \Phi_n(x_n) |0\right) =$$

$$\left( U^*_s U_t \Psi_1(y_1) \ldots \Psi_m(y_m) |0\right)$$

(A.2)

$$= U^*_r U_{r+s-1} U_t U_{r+s-1} \Phi_1 \left( x_1 + \frac{r-1}{2} \right) \ldots \Phi_n \left( x_n + \frac{r-1}{2} \right) \Psi_1 \left( y_1 - \frac{r-1}{2} \right) \ldots \Psi_m \left( y_m - \frac{r-1}{2} \right) |0\right),$$

where the coordinates are in the “$2/\pi$” Sliver frame (A.1), which implies some rescaling w.r.t. to (2.24) of [1], where the $2/\pi$ factor in (A.1) was omitted.

Upper Half Plane
In the BCFT of a free boson $X$ at the self-dual radius $R = 1$, with Neumann boundary conditions, consider the bulk winding mode

$$\nu_m(z, \bar{z}) = e^{im\tilde{X}(z, \bar{z})},$$

(A.3)

where $\tilde{X}(z, \bar{z}) = X_L(z) - X_R(\bar{z})$ is the T-dual field of $X(z, \bar{z})$, and the boundary marginal field

$$j(x) = i \sqrt{2} \partial X(x) = j(z) \bigg|_{z=x},$$

(A.4)

which is defined as a bulk chiral field placed at the boundary. The chiral closed string field $X(z)$ has the following two-point functions ($\alpha' = 1$):

$$\left\langle \frac{j(x) j(y)}{UHP} \right\rangle = \frac{1}{(x-y)^2}. $$

(A.6)

and it has the following OPE with the bulk winding mode

$$\nu_m(z, \bar{z}) j(x) \sim -\frac{m}{\sqrt{2}} \frac{1}{z-x} \nu_m(z, \bar{z}) + \frac{m}{\sqrt{2}} \frac{1}{\bar{z}-\bar{x}} \nu_m(z, \bar{z}).$$

(A.7)

We also have

$$\left\langle \frac{\tilde{X}(i, -i) \partial X(x)}{UHP} \right\rangle = -\frac{i}{1 + x^2},$$

(A.8)

and, using the Wick theorem,

$$\left\langle \nu_m(i, -i) j(x) \right\rangle_{UHP} = i m \sqrt{2} \frac{1}{1 + x^2} \left\langle \nu_m(i, -i) \right\rangle_{UHP}. $$

(A.9)

The one-point function is\textsuperscript{11}

$$\left\langle \nu_m(i, -i) \right\rangle_{UHP} = 2^{-m^2/2}. $$

(A.10)

In addition we have the following correlator for the auxiliary closed string field [23]:

$$\left\langle \nu_m(1-h_m, 1-h_m) (i, -i) \right\rangle_{UHP} = \frac{1}{4} 2^{m^2/2}. $$

(A.11)

\textsuperscript{11} This can be obtained from (A.1) of [23] by mapping the UHP to the disk, trading Dirichlet boundary conditions with Neumann and momentum with winding (T-duality) and setting $q = \text{im}$ there.
On the cylinder the chiral closed string field $X(z)$ has the following correlators [1]:

$$\langle X(z) X(w) \rangle_{C_N} = -\frac{1}{2} \log \left[ \sin \left( \frac{\pi}{N} (z - w) \right) \right],$$

$$\langle X(z) \partial X(w) \rangle_{C_N} = \frac{\pi}{2N} \cot \left( \frac{\pi}{N} (z - w) \right),$$

$$\langle \partial X(z) \partial X(w) \rangle_{C_N} = -\frac{\pi^2}{N^2} \csc^2 \left( \frac{\pi}{N} (z - w) \right).$$

and then

$$\langle j(x) j(y) \rangle_{C_N} = \frac{2\pi^2}{N^2} \csc^2 \left( \frac{\pi}{N} (z - w) \right).$$

Let us list for convenience the explicit correlators which are used in the main text:

- For $N = 0$:
  $$\langle c(0) V_m(i \infty) \rangle,$$

- For $N = 1$:
  $$\{ \langle c(0) V_m(i \infty) \rangle \} \{ \bar{X}(i \infty) j(0) \},$$

- For $N = 2$:
  $$\langle c(0) V_m(i \infty) \rangle \{ j(x_2) j(x_2) \} - m^2 \left( \left\{ \bar{X}(i \infty) j(0) \right\}^2 \right),$$

- For $N = 3$:
  $$\langle c(0) V_m(i \infty) \rangle \{ j(x_1) j(x_2) j(x_3) j(x_4) \} - \text{im}^3 \left( \left\{ \bar{X}(i \infty) j(0) \right\}^3 \right),$$

- For $N = 4$:
  $$\langle c(0) V_m(i \infty) \rangle \{ j(x_1) j(x_2) j(x_3) j(x_4) \} - m^2 \left( \left\{ \bar{X}(i \infty) j(0) \right\}^2 \right) \sum_{i, r = 1}^4 \langle j(x_i) j(x_r) \rangle$$

- For $N = 5$:
  $$\langle c(0) V_m(i \infty) \rangle \{ j(x_1) j(x_2) j(x_3) j(x_4) \} - \text{im}^3 \left( \left\{ \bar{X}(i \infty) j(0) \right\}^3 \right) \sum_{i, r = 1}^4 \langle j(x_i) j(x_r) \rangle$$

$$+ \text{im}^5 \left( \left\{ \bar{X}(i \infty) j(0) \right\}^5 \right).$$

This correlator significantly simplifies on a cylinder $C_N$, when the bulk operator (properly dressed with the ghosts and the auxiliary sector to acquire total weight zero; see (2.15)) is placed at the midpoint $i \infty$. In particular, thanks to the rotational invariance of $C_N$ we have

$$\langle V_m(i \infty) c(x) \rangle_{C_N} = \langle V_m(i \infty) c(0) \rangle_{C_N}$$

$$= \frac{N}{\pi} \langle V_m(i, -i) c(0) \rangle_{UHP}$$

$$= \frac{iN}{2\pi}. \quad (A.15)$$

The term containing the maximal number of contractions with the closed string is given by

$$\langle \text{im}^N \rangle_{\frac{N!}{N}} \{ c(0) V_m(i \infty) \} \times \left( \bar{X}(i \infty) N \right) \prod_{i=1}^N j(x_i) \right) \right)$$

$$= \langle \text{im}^N \rangle_{\frac{N!}{N}} \{ c(0) V_m(i \infty) \} \prod_{i=1}^N \bar{X}(i \infty) j(x_i) \right)$$

$$= \langle \text{im}^N \rangle_{\frac{N!}{N}} \{ c(0) V_m(i \infty) \} \left( \left\{ \bar{X}(i \infty) j(0) \right\}^N \right. \right) \right)$$

This correlator significantly simplifies on a cylinder $C_N$, when the bulk operator (properly dressed with the ghosts and the auxiliary sector to acquire total weight zero; see (2.15)) is placed at the midpoint $i \infty$. In particular, thanks to the rotational invariance of $C_N$ we have

$$\langle V_m(i \infty) c(x) \rangle_{C_N} = \langle V_m(i \infty) c(0) \rangle_{C_N}$$

$$= \frac{N}{\pi} \langle V_m(i, -i) c(0) \rangle_{UHP}$$

$$= \frac{iN}{2\pi}. \quad (A.15)$$

The term containing the maximal number of contractions with the closed string is given by

$$\langle \text{im}^N \rangle_{\frac{N!}{N}} \{ c(0) V_m(i \infty) \} \times \left( \bar{X}(i \infty) N \right) \prod_{i=1}^N j(x_i) \right) \right)$$

$$= \langle \text{im}^N \rangle_{\frac{N!}{N}} \{ c(0) V_m(i \infty) \} \prod_{i=1}^N \bar{X}(i \infty) j(x_i) \right)$$

$$= \langle \text{im}^N \rangle_{\frac{N!}{N}} \{ c(0) V_m(i \infty) \} \left( \left\{ \bar{X}(i \infty) j(0) \right\}^N \right. \right) \right)$$

where the only non-trivial correlator involving $\bar{X}$ is given by

$$\langle \bar{X}(i \infty) j(0) \rangle_{C_N} = \frac{\sqrt{2} \pi}{N}. \quad (A.18)$$
