Summary: Interleukin 17A (IL17A) is reported to be involved in many inflammatory processes, but its role in aortic valve diseases remains unknown. We examined the role of IL17A based on an ApoE⁻/⁻ mouse model with strategies as fed with high-fat diet or treated with IL17A monoclonal antibody (mAb). 12 weeks of high-fat diet feeding can elevate cytokines secretion, inflammatory cells infiltration and myofibroblastic transition of valvular interstitial cells (VICs) in aortic valve. Moreover, diet-induction accelerated interleukin 17 receptor A (IL17RA) activation in VICs. In an IL17A inhibition model, the treatment group was intra-peritoneally injected with anti-IL17A mAb while controls received irrelevant antibody. Functional blockade of IL17A markedly reduced cellular infiltration and transition in aortic valve. To investigate potential mechanisms, NF-κB was co-stained in IL17RA⁺ VICs and IL17RA⁺ macrophages, and further confirmed by Western blotting in VICs. High-fat diet could activate NF-κB nuclear translocation in IL17RA⁺ VICs and IL17RA⁺ macrophages and this process was depressed after IL17A mAb-treatment. In conclusion, high-fat diet can lead to IL17A upregulation, VICs myofibroblastic transition and inflammatory cells infiltration in the aortic valve of ApoE⁻/⁻ mice. Blocking IL17A with IL17A mAb can alleviate aortic valve inflammatory states.

Key words: aortic valve inflammation; interleukin 17A; NF-κB pathway; intensity correlation analysis; colocalization

Aortic valve stenosis remains as the most prevalent valvular disease in Western countries¹, affecting over 25% of all patients over the age of 65². Currently, there is no effective pharmacological therapy for aortic valve stenosis and surgical or interventional valve replacement serves as the only curative treatments. However, in patients who underwent transcatheater aortic valve replacement, up to 30% had oxygen dependence³ and 60% had significant lung disease, which has been associated with increased morbidity and mortality⁴. Others reported unexpected side effects including chronic kidney disease and liver disease, all of which are considered to contribute to deaths after aortic valve surgery⁵.

Inflammation plays a key role in aortic valve stenosis, ultimately leading to aortic valve calcification. Low density lipoprotein (LDL) cholesterol has also been suggested to underlie the progression of inflammatory aortic valve stenosis⁶. High-fat diet (HFD) can induce significant aortic valve calcification in ApoE⁻/⁻ mice⁷, significantly increasing transvalvular peak jet velocity and markedly decreasing aortic valve area (AVA) and AVA index. Similarly, significant calcium deposits in aortic valve of HFD-treated ApoE⁻/⁻ mice by alizarin red staining⁷. Currently, ApoE⁻/⁻ mice fed with HFD are the common animal models for aortic valve inflammation study⁷–⁹.

In recent years, interleukin 17A (IL17A) was reported to coordinate local tissue inflammation via inducing the release of proinflammatory cytokines and neutrophil-mobilizing chemokines in several cell families¹⁰,¹¹. And recent studies implicate that IL17A can also accelerate atherosclerotic plaque development via its receptor IL17RA¹²,¹³, and vascular inflammation decreased in the IL17A-deficient mice¹⁴. Besides, IL17A is primarily produced by Th17 cells, a subset of CD4⁺ T cells, and Th17 cells have also been observed in atherosclerotic plaques both in human and animals¹⁵.
These findings have stroked our view for uncovering the character of IL17A/IL17RA performance in aortic valve inflammation.

We therefore sought to accurately examine the role of IL17A in aortic valve inflammation using HFD mouse models, and blocking IL17A with an anti-IL17A antibody (mAb) in ApoE−/− mice.

1 MATERIALS AND METHODS

1.1 Affymetrix Microarray Data and Data Analysis

Microarray data of GSE77287 were obtained from the Gene Expression Omnibus (GEO; https://www.ncbi.nlm.nih.gov/geo/) database. Calcific aortic valve tissues were extracted from patients with calcific aortic valve disease (CAVD) who underwent aortic valve replacement, and normal controls were obtained from non-CAVD cardiac transplant recipient hearts[16]. Gene expression profiles of three samples of calcific aortic valves and three age-matched normal controls were performed using Affymetrix Gene Chip microarrays[16]. The raw data and annotation files were downloaded for subsequent analysis, based on Affymetrix Human Gene 2.0 ST Array. The original data were pre-processed with background correction, normalization and calculating expression using the ‘affy’ package in R (version 3.4.2). Heatmap and PPI network were applied as indicated[17].

1.2 Animals

Eight-week (wk)-aged male ApoE−/− mice were purchased from the local experimental animal center (Wuhan, China). Mice were housed in a controlled environment (20±2°C, 12 h/12 h light/dark cycle) and had free access to water and diet. The experiments were randomly assigned into four groups: (1) normal group, 8-wk-aged ApoE−/− mice receiving normal diet (ND) for 12 weeks; (2) HFD group, 8-wk-aged ApoE−/− mice receiving 0.25% HFD for 12 weeks; (3) IL17A mAb-treated group, 8-wk-aged ApoE−/− mice receiving anti-mouse IL17A mAb (100 μg; R&D Systems, USA) intraperitoneally (i.p.) once a week and 0.25% HFD for 12 weeks; (4) irrelevant IgG-treated group (control group), 8-wk-aged ApoE−/− mice receiving irrelevant IgG (100 μg; R&D Systems, USA) i.p. once a week and 0.25% HFD for 12 weeks.

All the mice were sacrificed at 20th week, and aortic valves were collected and stored at −80°C until cutting. All the animal procedures were performed according to the Helsinki Declaration and institutional guidelines at the laboratory animal center of Huazhong University of Science and Technology.

1.3 Immunohistochemistry

The extent of aortic valve was assessed by immunohistochemistry. Lipid depositions were assessed following Oil Red O staining and nuclei were stained with hematoxylin. CD4+ T cells, valvular interstitial cells (VICs) and macrophages were stained in aortic valves. Briefly, after blocking by horse serum (Sigma Aldrich, USA), samples were reacted with rabbit anti-mouse CD4 (1:500 dilution, Abcam, ab183685, UK), FITC-conjugated mouse anti-mouse smooth muscle cell α-actin (αSMA, 1:500, Sigma Aldrich, F3777, USA), rat anti-mouse CD68 (1:100 dilution, Serotec, MCA1957, UK), rat anti-mouse IL17A (1:100 dilution, R&D, MAB721, USA), goat anti-mouse IL17RA (1:100 dilution, R&D, AF448, USA) and rabbit anti-mouse NF-κB (p65) (1:100 dilution, Santa Cruz, sc-372, USA) antibodies at 4°C overnight in the dark, respectively. After incubation with secondary antibody for 1 h at room temperature in the dark, nuclei were counterstained with DAPI (Vector Laboratories, USA). Images were recorded and analyzed with Image J software.

1.4 Quantitative Assessment of Colocalization

Intensity correlation analysis (ICA)[18] was performed on immunofluorescent images to assess the percentage of labelled IL17A+ CD4+ T cells (Th17 cells), IL17RA− CD4+ T cells, IL17RA+ VICs and IL17RA+ macrophages in aortic valves. Briefly, WCIF Image J software was used to determine colocalized red and green pixel areas. We obtained intensity correlation quotient (ICQ), \( \Sigma (A-a)(B-b) \) value, with dependent staining 0<ICQ≤+0.5. The percentage of colocalization was calculated relative to total aortic valve area for that field. Online manual for correlation analysis is referred to http://www.facilities. uhnresearch.ca/wcif/imagej/colour_analysis.htm.

1.5 Plasma Lipid and ELISA Analysis

Total plasma cholesterol and triglycerides were enzymatically measured using the Cholesterol/Triglyceride Assay Kit (Roche-Hitachi, Switzerland) according to the manufacturer’s instructions. Serum IL17A and other cytokines levels were measured with IL17A, IL6 and TNF-α ELISA (Elabscience, China) according to the manufacturer’s protocols.

1.6 Cell Harvest and Western Blotting Analysis

VICs were isolated from murine aortic valve leaflets and cultured as previously described with some modifications[16]. Briefly, aortic valve leaflets were digested in collagenase (2.5 mg/mL in M199 medium) for 30 min at 37°C. After removing immune and endothelial cells by vortex, a milder solution of collagenase medium was used (0.8 mg/mL) for 3 h at 37°C. Cells were collected by centrifugation at 1200 × g for 5 min, and then resuspended and cultured in DMEM containing 4.5 g/L glucose, penicillin G, streptomycin, and 10% fetal bovine serum. Cells were harvested and homogenized in RIPA Lysis and Extraction Buffer with protease and phosphatase inhibitor cocktails (Pierce, USA). Nuclear proteins were prepared using NE-PER Nuclear Extraction Reagents (Pierce, USA). All these procedures were performed according to the manufacturer’s protocols. Equal amounts of protein.
were resolved by SDS-PAGE (10% resolving gel with 4% stacking) and transferred to PVDF membranes. Membranes were blocked with buffer containing 10% non-fat milk and 5% BSA in TBS-T (50 mmol/L Tris–HCl, pH 8.0, 150 mmol/L NaCl, and 0.1 % Tween-20), and then incubated with NF-κB (p65) (1:500 dilution, Bioworld Technology, T429, USA) and β-actin (1:1000 dilution, Santa Cruz, sc-8432, USA). Blots were washed in TBS-T and incubated with appropriate HRP-conjugated secondary antibodies. The immune complexes were then visualized using ECL reagent (Beyotime, China). Image J software was used to analyze the area and density of protein band.

1.7 Quantitative Real-time RT-PCR Validation

The target genes IL17A and IL17RA were validated by quantitative real-time RT-PCR. Total RNA was isolated and cDNA was transcribed using PrimeScript RT Reagent Kit with gDNA Eraser (TaKaRa, Japan) according to the manufacturer’s instructions. Primers were searched from Primerbank (https://pga.mgh.harvard.edu/primerbank/) and listed in table 1. All data were normalized to GAPDH. 2^−ΔΔCt methods were recruited to calculate the relative expression level.

1.8 Statistics

Statistical calculations were performed using GraphPad Prism 7 (GraphPad Software Inc., USA). With unpaired Student’s t-test or sign test of the normal approximation means, data were expressed as mean±SEM. The P value <0.05 was considered significant.

2 RESULTS

2.1 Up-regulation of IL17A-IL17RA Axis in Aortic Valve of HFD ApoE−/− Mice

Firstly, IL17A-IL17RA-related genes from the analysis of GSE77287 were selected based on PPI network. Relative expression of these genes was shown in fig. 1A–1C.

To determine whether IL17A and IL17RA levels are altered in aortic valve inflammation, ApoE−/− mice models were established with HFD and aortic valves were collected from both ND and HFD ApoE−/− mice. Oil Red O staining verified the histomorphology changes. Prominent lipid-rich areas were observed and mostly located in the superficial fibrosa layer (fig. 1D).

Furthermore, we analyzed the composition of aortic valves. Increased VICs myofibroblastic differentiation was companied by enhanced CD4+ T cells and macrophages infiltration in aortic valve (fig. 1G and 1I, for VICs, ND: 8.18%±2.70%, HFD: 17.22%±4.56%, P<0.01; fig. 1F and 1I, for CD4+ T cells, ND: 2.77%±1.06%, HFD: 9.06%±2.60%, P<0.01; fig. 1H and 1I, for macrophages, ND: 3.38%±1.19%, HFD: 7.65%±2.52%, P<0.05), indicating the valves suffered from inflammation. Previous literatures also supported activation of myofibroblastic VICs, CD4+ T cells and macrophages in inflammatory aortic valve[19, 20].

Furtherly, as shown in fig. 1E and table 2, results suggested an increase of IL17A+ CD4+ T cells (Th17 cells) in HFD-induced aortic valve (fig. 1E), as well as serum cytokines concentration, including IL17A, IL6 and TNF-α (table 2). A visual inspection of the staining in aortic valve provided suggestive evidence for colocalization of IL17A with CD4. Moreover, the ICA analysis was consistently in favor of such an association, concerning both the staining amplitude (A-a) (B-b) plots and positive ICQ values (ICQ=+0.15, $P_{\text{sign-test}}<0.001$, fig. 1E).

Double immunofluorescent staining indicated IL17RA colocalized with CD4 (fig. 1F), αSMA (fig. 1G) and CD68 (fig. 1H) in aortic valve. ICA analysis of GSE77287 were selected based on PPI network. Relative expression of these genes was shown in fig. 1A–1C.

Table 1 The primers of IL17A-IL17RA-related genes

| Gene      | Forward                          | Reverse                          |

Table 2 Lipid profile and serum levels of cytokines

| Parameters       | ND ApoE-/- (n=7)            | HFD ApoE-/- (n=7) | P value |
|------------------|-------------------------------|-------------------|---------|
| Triglycerides (mg/dL) | 92.64±31.16                  | 143.23±68.32      | n.s.    |
| Total cholesterol (mg/dL) | 387.97±196.60               | 512.73±213.62     | 0.05    |
| IL17A (pg/mL)    | 92.45±36.13                  | 153.59±33.50      | <0.05   |
| IL6 (pg/mL)      | 474.82±5.70                  | 623.21±4.77       | <0.01   |
| TNF-α (pg/mL)    | 445.04±39.12                 | 515.82±13.73      | <0.01   |

On the day of tissue harvesting (20 weeks), serum levels of cytokines (pg/mL) as well as lipid profile in the serum were determined by ELISA. Data are expressed as mean±standard error of the mean. n.s., not significant.
2.2 Blocking IL17A Alleviated Inflammatory State of Aortic Valve of HFD ApoE-/- Mice

Twelve-week HFD increased IL17A expression in aortic valve. As this potential point, we next sought to address the contribution of IL17A to valvular cells by inactivating IL17A with IL17A mAb. IL17A mAb-treated mice were introduced as a validated mouse model[14, 20]. Treatment with IL17A mAb resulted in significantly reduced serum cytokines secretion (e.g., IL17A, IL6, TNF-α) (table 3). Staining with Oil Red O in IL17A mAb-treated mice presented lower amounts of lipid-rich areas (fig. 2A). Furthermore, αSMA+ area in IL17A mAb-treated and control groups was 12.19%±2.37% and 20.65%±3.99% respectively (P<0.01, fig. 2D and 2G). The double immunofluorescent staining revealed a reduced number of IL17A+ T cells (P<0.05, fig. 2B and 2F) and IL17RA+ VICS (P<0.01 (fig. 2D and 2H). However, IL17RA+ CD4+ T cells and macrophages showed no significant difference (fig. 1J and 1L).

Table 3 Lipid profile and serum levels of cytokines

| Parameters          | IL17A mAb-treated (n=8) | Control (n=8) | P value |
|---------------------|-------------------------|---------------|---------|
| Triglycerides (mg/dL) | 147.64±76.16            | 150.30±50.94 | n.s.    |
| Total cholesterol (mg/dL) | 395.39±102.23          | 439.02±130.62 | n.s.    |
| IL17A (pg/mL)       | 48.16±26.82             | 151.20±52.80 | <0.01   |
| IL6 (pg/mL)         | 474.15±12.19            | 571.01±44.16 | <0.01   |
| TNF-α (pg/mL)       | 475.94±9.22             | 569.88±20.61 | <0.01   |

On the day of tissue harvesting (20 weeks), serum levels of cytokines (pg/mL) as well as lipid profile in the serum were determined by ELISA. Data are expressed as mean±SEM. n.s., not significant.
cell particle percentage of IL17RA+ VICs and IL17RA+ macrophages in total aortic valve, we noticed HFD also activated NF-κB nuclear translocation in both IL17RA+ VICs (fig. 3A) and IL17RA+ macrophages (fig. 3B).
IL17RA are the main component of aortic valve and contribute to normal function, HFD ApoE<sup>−/−</sup> mice led to significant NF-κB intranuclear translocation in VICs (fig. 3E) and IL17RA<sup>−/−</sup> macrophages (fig. 3D), although NF-κB<sup>−</sup> cells counting results showed no significant difference in IL17RA<sup>−/−</sup> VICs (P<0.064, fig. 3C).

The results were further confirmed in VICs by Western blotting as shown in fig. 3E and 3F. As VICs are the main component of aortic valve and contribute to normal function, HFD ApoE<sup>−/−</sup> mice led to significant NF-κB intranuclear translocation in VICs (fig. 3E). After IL17A mAb treatment, the NF-κB translocation was depressed (fig. 3F).

### 2.4 Validation of IL17A and IL17RA Expression Data by Real-time RT-PCR

The expression levels of IL17A-IL17RA genes were detected using qRT-PCR. The result showed that...
the expression levels of IL17RA \((P<0.01)\) and IL17A \((P<0.01)\) were significantly increased in HFD ApoE\(^{-/-}\) mice samples (fig. 4A and 4B). As compared with the control group, IL17RA \((P<0.05)\) and IL17A \((P<0.01)\) were noticeably decreased in IL17A mAb-treated group (fig. 4C and 4D).

**Fig. 4** qRT-PCR results of IL17A and IL17RA between normal diet and HFD ApoE\(^{-/-}\) mice (A, B), and between IL17A mAb-treated and control mice (C, D). All data were normalized to GAPDH. \(2^{-\Delta\Delta C_t}\) methods were recruited to calculate the relative expression level. \(^*P<0.01, \ ^*P<0.05\)

### 3 DISCUSSION

Aortic valve disease is a significant culprit in cardiovascular disease and results from a complex interaction between hypercholesterolemia state and chronic inflammation. The development of aortic valve disease is characterized by three primary processes: lipid accumulation, inflammation, and ultimate calcification\[^{[23, 24]}\]. Inflammation is the core point to all stages of aortic valve pathology. Previous pathological studies suggested that stenotic aortic valve is rich in inflammatory cells and exhibits myofibroblastic differentiation in VICs—the most prevalent cells in aortic valve and responsible for maintaining normal valve structure and function. In inflammatory conditions, quiescent VICs will be activated into myofibroblasts\[^{[25, 26]}\]. \(\alpha\)SMA, a cytoskeletal isoform of actin, is the phenotypic marker for VICs. The transition from VICs to myofibroblasts is also a critical change in valvular calcified pathology, markedly increasing the \(\alpha\)SMA positive staining area. Overexpression of \(\alpha\)SMA increases the VICs contractility and calcific nodule formation, whereas knockdown of \(\alpha\)SMA with siRNAs reverses these changes\[^{[27]}\]. Myofibroblastic transition is thought to contribute directly to the thickening and stiffening of valve and the subsequent calcification\[^{[28]}\]. CD4\(^+\) T cells and macrophages are the principal infiltrated inflammatory cell types in various valvular heart diseases\[^{[29]}\]. Inflammatory macrophages, as indicated by CD68, promote valvular cells calcification in a cathepsin S-dependent manner in aortic valve inflammatory disease\[^{[30]}\]. Our current study employed HFD ApoE\(^{-/-}\) mice model as a well-established model for aortic valve inflammation, and displayed the increase of cholesterol and IL17A during aortic valve inflammation. At the same time, we observed significantly increased infiltration of inflammatory cells such as macrophages and CD4\(^+\) T cells, and myofibroblastic transition of VICs.

In our study, IL17A/IL17RA contribute to inflammation by mean of cellular infiltration and activation, e.g., T cells and macrophages infiltration suppressing IL17A with IL17A mAb weakened levels of these inflammatory responses.

IL17A, which is primarily secreted by Th17 cells, participates in local tissue inflammation via inducing release of proinflammatory cytokines and neutrophil-mobilizing chemokines in various cell types\[^{[30]}\]. IL17RA is expressed in smooth muscle cells under basal conditions\[^{[31]}\]. In atherosclerotic disease, IL17A/IL17RA are involved in systemic and vascular inflammation in response to HFD and are implicated in the progression of the atherosclerotic plaque\[^{[12]}\]. However, the role of IL17A in different stages of aortic valve inflammation remains unknown. In the current study, our data revealed that IL17A-CD4\(^+\) T cells were increased in HFD aortic valve. Immunofluorescent staining also stated that IL17RA was raised significantly in VICs. Blockade of IL17A reversed the changes. Taken together, these findings indicated that IL17A and IL17RA were involved in VICs myofibroblastic transition, and CD4\(^+\) T cells and macrophages infiltration in aortic valve inflammatory state.

Colocalization analysis is a vital section of co-expression study. Unlike the usual dye-overlap method easily misled by subjectivity, it identifies protein pairs and calculates colocalization area. The same results may also be acquired by using flow cytometry, but it will run out of almost all the treasured tissues. Additionally, we can also inquire a statistically testable, single-value assessment ICQ between the stained protein pairs. We used this co-expression method to assess IL17RA colocalized in the specific cells, not just IL17RA positive area in the whole aortic valve. At last, we obtained the results that IL17RA was significantly activated in myofibroblastic VICs in the HFD aortic valves.

In our study, IL17A/IL17RA contribute to inflammation by mean of cellular infiltration and activation, e.g., T cells and macrophages infiltration suppressing IL17A with IL17A mAb weakened levels of these inflammatory responses.
and VICs myofibroblastic transition. Further, it can be speculated that IL17A activates VICs via IL17RA and subsequently triggers activation of NF-kB, thereby inducing NF-kB-dependent gene transcription, as also reported in some publications for several other cell types. On the other hand, as the number of VICs is various in different experiment groups, in order to avoid the bias, we used (NF-kB+ IL17RA+ VICs)/ (IL17RA+ VICs)% value, instead of NF-kB positive area or cells in the whole aortic valve, to assess NF-kB translocation. At last we illustrated that the NF-kB was responsible for IL17A/IL17RA-related inflammation in VICs on HFD or IL17A mAb treatment mice.

In conclusion, we demonstrated for the first time that IL17A/IL17RA were involved in VICs myofibroblastic transition and inflammatory cells infiltration in the HFD ApoE−/− mice, which is the downstream regulation mediated by NF-kB. Therefore, blocking IL17A could probably provide potential prophylactic and therapeutic potential for different stages of aortic valve diseases in the future.
