POSITIVITY OF DIRECT IMAGES OF FIBERWISE RICCI-FLAT METRICS ON CALABI-YAU FIBRATIONS

YOUNG-JUN CHOI

Abstract. Let $X$ be a Kähler manifold which is fibered over a complex manifold $Y$ such that every fiber is a Calabi-Yau manifold. Let $\omega$ be a fixed Kähler form on $X$. By Calabi and Yau’s theorem, there exists a unique Ricci-flat Kähler form $\rho|_{X_y}$ for each fiber, which is cohomologous to $\omega|_{X_y}$. This family of Ricci-flat Kähler forms $\rho|_{X_y}$ induces a smooth $(1, 1)$-form $\rho$ on $X$ with a normalization condition. In this paper, we prove that the direct image of $\rho^{n+1}$ is positive on the base $Y$ and that there exists a lower bound of $\rho$ which is given by the Green kernel on each fiber and the Weil-Petersson metric on $Y$. We also discuss several byproducts, among them the local triviality of families of Calabi-Yau manifolds.

1. Introduction

Let $p : X \to Y$ be a proper surjective holomorphic mapping between complex manifolds $X$ and $Y$ whose differential has maximal rank everywhere such that every fiber $X_y := p^{-1}(y)$ is a compact Kähler manifold. This is called a smooth family of compact Kähler manifolds or a compact Kähler fibration. If every fiber $X_y$ is a Calabi-Yau manifold, i.e., a compact Kähler manifold whose canonical line bundle $K_{X_y}$ is trivial, then the family is called a smooth family of Calabi-Yau manifolds or a Calabi-Yau fibration.

2010 Mathematics Subject Classification. 32Q25, 32Q20, 32G05, 32W20.

If \((X, \omega)\) is a Kähler manifold, then a celebrated theorem due to Calabi and Yau implies that on each fiber \(X_y\), there exists a unique Ricci-flat metric \(\omega_{KE,y}\) in the cohomology class \([\omega]_{X_y}\). This family of Ricci-flat metrics induces a fiberwise Ricci-flat metric on the total space \(X\).

The main theorem of this paper is the following:

**Theorem 1.1.** Let \(p : X \to Y\) be a smooth family of Calabi-Yau manifolds. Suppose that \(X\) is a Kähler manifold equipped with a Kähler form \(\omega\). Let \(\omega_{KE,y}\) be the unique Ricci-flat form in the cohomology class \([\omega]_{X_y}\). Then there exists a unique smooth function \(\varphi \in C^\infty(X)\) which satisfies the following properties:

(i) \(\int_{X_y} \varphi(\omega_{KE,y})^n = 0\) for every \(y \in Y\),
(ii) \(\omega + dd^c\varphi|_{X_y}\) is a Ricci-flat Kähler form on \(X_y\) for every \(y \in Y\) and
(iii) \(p_*(\omega + dd^c\varphi)^{n+1}\) is a positive \((1,1)\)-form on \(Y\).

Here \(dd^c\) means the real operator defined by
\[
dd = \frac{\sqrt{-1}}{2} (\partial - \bar{\partial}).
\]

Then we have \(dd^c = \sqrt{-1}\partial\bar{\partial}\). We call the \((1,1)\)-form \(\rho := \omega + dd^c\varphi\) which satisfies the property (ii) a fiberwise Ricci-flat metric or a fiberwise Ricci-flat Kähler form on a Calabi-Yau fibration \(p : X \to Y\). Note that a real \((1,1)\)-form on \(X\) satisfying (ii) is not uniquely determined. With the normalization condition (i), the fiberwise Ricci-flat metric is uniquely determined. From now on, the fiberwise Ricci-flat metric on a Calabi-Yau fibration means the real \((1,1)\)-form which satisfies (i) and (ii). It is remarkable to note the following:

- Theorem 1.1 basically deals with a smooth family of polarized Calabi-Yau manifolds in the sense of deformation theory.
- Theorem 1.1 does not assume the compactness of the base \(Y\).

For a family of canonically polarized compact Kähler manifolds, we have a fiberwise Kähler-Einstein metric by the similar way. The positivity of the fiberwise Kähler-Einstein metric on a family of compact Kähler manifolds was first studied by Schumacher. In his paper [30], he has proved that the fiberwise Kähler-Einstein metric on a family of canonically polarized compact Kähler manifolds is semi-positive. Moreover he has also proved that it is strictly positive if the family is effectively parametrized. This is equivalent to the semi-positivity or positivity of the relative canonical line bundle of the family, respectively. Păun have shown that if the relative adjoint line bundle is positive on each fiber, then it is semi-positive on the total space by generalizing the method of Schumacher ([28]). Guenancia also have proved the semi-positivity of the fiberwise conic singular Kähler-Einstein metric ([16]). In case of a family of complete Kähler manifolds, Choi have proved that the fiberwise Kähler-Einstein metric on a family of bounded pseudoconvex domains is semi-positive or positive if the total space is pseudoconvex or strongly pseudoconvex, respectively ([9, 10]).

The proof of Schumacher’s theorem starts with the following identity from [31]:

For a real \((1,1)\)-form \(\tau\) on \(X\),
\[
\tau^{n+1} = c(\tau)\tau^n \sqrt{-1} ds \wedge d\bar{s}
\]
where $\tau^n$ is the $n$-fold exterior power divided by $n!$. Here $c(\tau)$ is called a *geodesic curvature* of $\tau$. (For the detail, see Section 2.1.)

Now suppose that $\tau$ is positive-definite on each fiber $X_y$. Then (1.1) says that $\tau$ is semi-positive or positive if and only if $c(\tau) \geq 0$ or $c(\tau) > 0$, respectively. Schumacher have proved that the geodesic curvature of the fiberwise Kähler-Einstein metric on a family of canonically polarized compact Kähler manifolds satisfies a certain second order linear elliptic partial differential equation. This PDE gives a lower bound of the geodesic curvature by the maximum principle or an lower bound estimate on the heat kernel.

However, in case of a Calabi-Yau fibration, the PDE which the geodesic curvature of fiberwise Ricci-flat metric satisfies is of a different type from the previous one. (See Section 4.) In particular, it does not give a lower bound of the geodesic curvature.

This is why Schumacher’s method does not give positivity or semi-positivity of the fiberwise Ricci-flat metric. But the approximation procedure of complex Monge-Ampère equations, it is possible to obtain a lower bound of the direct image of the fiberwise Ricci-flat metric (see Section 5). This is the main contribution of this paper.

This difference of the PDEs, which the fiberwise Kähler-Einstein metric on a family of canonically polarized manifolds and the fiberwise Ricci-flat metric on a family of Calabi-Yau manifold satisfy, arises from the difference of complex Monge-Ampère equations which give the Kähler-Einstein metrics. More precisely, the complex Monge-Ampère equation of type:

\begin{equation}
(\omega + dd^c \varphi)^n = e^{\lambda \varphi + f} \omega^n,
\end{equation}

for some constant $\lambda > 0$ and some suitable smooth function $f$, gives the Kähler-Einstein metric on a canonically polarized compact Kähler manifold. On the other hand, the complex Monge-Ampère equation of type:

\begin{equation}
(\omega + dd^c \varphi)^n = e^{\bar{f}} \omega^n
\end{equation}

for some suitable smooth function $\bar{f}$, gives the Kähler-Einstein (in this case Ricci-flat) metric on a Calabi-Yau manifold. It is remarkable to note that if $f$ and $\bar{f}$ coincide, then (1.2) converges to (1.3) as $\lambda \to 0$. Then by the a priori estimate for complex Monge-Ampère equation, it is well known that the solutions $\varphi_\lambda$ of (1.2) converges to the solution of (1.3) (see Section 3). This is the key observation of the proof of approximation procedures which we already mentioned.

Although we cannot obtain the positivity of the fiberwise Ricci-flat metric $\rho$ on $X$, Theorem 1.1 gives a lower bound of $\rho$ which is given by the Green kernel of each fiber and the Weil-Petersson metric on the base $Y$.

**Theorem 1.2.** Let $G_y(z, w)$ be the Green kernel of $-\Delta_{\omega_{KE,y}}$ on $X_y$ which is normalized by

$$\int_{X_y} G_y(z, w) dV_{\omega_{KE,y}}(z) = 0.$$

Let $-K(y)$ with $K(y) \geq 0$ be the lower bound of the Green kernel, i.e.,

$$\inf_{(z, w) \in X_y \times X_y} G_y(z, w) = -K(y).$$

Then $\rho + K(y) \omega^{WP}$ is positive on $X$, where $\omega^{WP}$ is the Weil-Petersson metric on $Y$. (About the Green kernel, see [2].)
It is remarkable to note that the lower bound of the Green kernel of a compact Kähler manifold is bounded from below by a constant which depends only on the geometry of the compact Kähler manifold, more precisely, the Ricci curvature, the diameter and the volume (Theorem 3.2 in [3]). Since the Ricci curvature of every fiber vanishes and the volume of every fiber is same (see Subsection 3.2), the fiberwise constant $K(y)$ is uniformly bounded from below if the diameter of every fiber is bounded.

In the meantime, the second order elliptic PDE for the geodesic curvature $c(\rho)$ of the fiberwise Ricci-flat metric of a Calabi-Yau fibration gives several informations about Calabi-Yau fibrations. Among them, there is a result about the local triviality of Calabi-Yau fibrations.

**Theorem 1.3.** Let $p : X \rightarrow Y$ be a smooth family of Calabi-Yau manifolds. Let $E := p_\ast(K_{X/Y})$ be the direct image bundle of the relative canonical line bundle $K_{X/Y}$. We denote by $\Theta(E)$ the curvature of the natural $L^2$ metric of $E$. If $\Theta(E)$ vanishes along a complex curve, then the family is trivial along the complex curve. A similar result was obtained by Tosatti in [37] (cf. see also [14]). Jolany informed the author that he also proved Theorem 1.3 and some estimates of this paper ([24]).

**Acknowledgement.** The author happily acknowledges his thanks to Mihai Păun who suggested this problem, shared his ideas and Dano Kim for very helpful discussions. He is also indebted to Hoang Lu Chinh for teaching him the approximation process of complex Monge-Ampère equations, Bo Berndtsson for enlightening discussions about many topics, including the direct image bundles and Griffiths theorem, Henri Guenancia for helpful comments about Proposition 3.7, Long Li for many helpful comments about Green kernels, Philippe Eyssidieux for many helpful comments and discussions and Jean-Pierre Demailly for enlightening comments including the natural hermitian metric on a family of Calabi-Yau manifolds. Finally, he would like to thank Yuxin Ge for informing him the error of the previous version.

**2. Preliminaries**

Let $p : X^{n+d} \rightarrow Y^d$ be a smooth family of Kähler manifolds. Taking a local coordinate $(s^1, \ldots, s^d)$ of $Y$ and a local coordinate $(z^1, \ldots, z^n)$ of a fiber of $p$, $(z^1, \ldots, z^n, s^1, \ldots, s^d)$ forms a local coordinate of $X$ such that under this coordinate, the holomorphic mapping $p$ is locally given by

$$p(z^1, \ldots, z^n, s^1, \ldots, s^d) = (s^1, \ldots, s^d).$$

We call this an *admissible coordinate of $p$.*

Throughout this paper we use small Greek letters, $\alpha, \beta, \cdots = 1, \ldots, n$ for indices on $z = (z^1, \ldots, z^n)$ and small roman letters, $i, j, \cdots = 1, \ldots, d$ for indices on $s = (s^1, \ldots, s^d)$ unless otherwise specified. For a properly differentiable function $f$ on $X$, we denote by

$$f_\alpha = \frac{\partial f}{\partial z^\alpha}, \quad f_\bar{\beta} = \frac{\partial f}{\partial \bar{z}^\beta}, \quad \text{and} \quad f_i = \frac{\partial f}{\partial s^i}, \quad f_j = \frac{\partial f}{\partial \bar{s}^j},$$

where $z^\bar{\beta}$ and $s^\bar{j}$ mean $\overline{z^\beta}$ and $\overline{s^j}$, respectively. In case $d = 1$, we denote by $f_s = \frac{\partial f}{\partial s}$ and $f_\bar{s} = \frac{\partial f}{\partial \bar{s}}$. 

If there is no confusion, we always use the Einstein convention. For simplicity we denote by \( v_i := \partial / \partial s^i \). If \( d = 1 \), then we denote by \( v := \partial / \partial s \).

2.1. **Horizontal lifts and geodesic curvatures.** For a complex manifold \( M \), we denote by \( T^*M \) the complex tangent bundle of type \((1,0)\).

**Definition 2.1.** Let \( V \in T^*Y \) and \( \tau \) be a real \((1,1)\)-form on \( X \). Suppose that \( \tau \) is positive definite on each fiber \( X_y \).

1. A vector field \( V_\tau \) of type \((1,0)\) is called a *horizontal lift* of \( V \) if \( V_\tau \) satisfies the following:
   (i) \( \langle V_\tau, W \rangle_\tau = 0 \) for all \( W \in T^*X_y \),
   (ii) \( d\pi(V_\tau) = V \).

2. The *geodesic curvature* \( c(\tau)(V) \) of \( \tau \) along \( V \) is defined by the norm of \( V_\tau \) with respect to the sesquilinear form \( \langle \cdot , \cdot \rangle_\tau \) induced by \( \tau \), namely,

\[
c(\tau)(V) = \langle V_\tau, V_\tau \rangle_\tau.
\]

**Remark 2.2.** Let \((z^1, \ldots, z^n, s^1, \ldots, s^d)\) be an admissible coordinate of \( p \). Then we can write \( \tau \) as follows:

\[
\tau = \sqrt{-1} \left( \tau_{\beta \bar{\alpha}} ds^\beta \wedge ds^\bar{\alpha} + \tau_{\alpha \bar{\beta}} dz^\alpha \wedge d\bar{z}^\beta + \tau_{\alpha \bar{\beta}} dz^\alpha \wedge d\bar{z}^\beta \right).
\]

Since \( \tau \) is positive-definite on each fiber \( X_y \), the matrix \((\tau_{\alpha \bar{\beta}})\) is invertible. We denote by \((\tau^{\alpha \bar{\beta}})\) the inverse matrix. Then it is easy to see that the horizontal lift of \( \partial / \partial s^i \) is given as follows.

\[
\left( \frac{\partial}{\partial s^i} \right)_\tau = \frac{\partial}{\partial s^i} - \tau_{\bar{\alpha} \beta} \tau^{\beta \bar{\alpha}},
\]

in particular, any horizontal lift with respect to \( \tau \) is uniquely determined.

On the other hand, the geodesic curvature \( c(\tau)(v_i) \) is computed as follows:

\[
c(\tau)(v_i) = \langle (v_i)_\tau, (v_i)_\tau \rangle_\tau
\]

\[
= \left\langle \frac{\partial}{\partial s^i} - \tau_{\bar{\alpha} \beta} \tau^{\beta \bar{\alpha}}, \frac{\partial}{\partial s^i} - \tau_{\bar{\alpha} \beta} \tau^{\beta \bar{\alpha}} \right\rangle_\tau
\]

\[
= \tau_{i\bar{i}} - \tau_{i\bar{\alpha}} \tau^{\bar{\alpha} \beta} \tau_{\bar{\beta} \gamma} - \tau_{i\bar{\alpha}} \tau^{\bar{\alpha} \beta} \tau_{\bar{\beta} \gamma} + \tau_{i\bar{\alpha}} \tau^{\bar{\alpha} \beta} \tau_{\bar{\beta} \gamma} - \tau_{i\bar{\alpha}} \tau^{\bar{\alpha} \beta} \tau_{\bar{\beta} \gamma}
\]

\[
= \tau_{i\bar{i}} - \tau_{i\bar{\alpha}} \tau^{\bar{\alpha} \beta} \tau_{\bar{\beta} \gamma},
\]

because \( \tau \) is a real \((1,1)\)-form.

**Remark 2.3.** The real \((1,1)\)-form \( \tau \) in Definition 2.1 induces a hermitian metric on the relative canonical line bundle \( K_{X/Y} \) as follows:

Let \((z^1, \ldots, z^n, s^1, \ldots, s^d)\) be an admissible coordinate in \( X \). Since \( \tau \) is positive-definite on each fiber, \((\tau_{\alpha \bar{\beta}})\) is positive-definite. Hence

\[
\sum \tau_{\alpha \bar{\beta}}(z, s) dz^\alpha \wedge d\bar{z}^\beta
\]

gives a Kähler metric on each fiber \( X_s \). It follows that

\[
(2.2) \quad \det(\tau_{\alpha \bar{\beta}}(z, s))^{-1}
\]

gives a hermitian metric on the relative line bundle \( K_{X/Y} \). We denote this metric by \( h^\tau_{X/Y} \). The curvature form \( \Theta_{h^\tau_{X/Y}}(K_{X/Y}) \) of \( h^\tau_{X/Y} \) is given by

\[
\Theta_{h^\tau_{X/Y}}(K_{X/Y}) = dd^c \log(\tau_{\alpha \bar{\beta}}(z, s)).
\]
It is obvious that the curvature is also written as follows:
\[
\Theta_{h_{X/Y}}(K_{X/Y}) = dd^c \log \det (\tau^n \wedge dV_s),
\]
where we denote by \( \tau^n \) the \( n \)-fold exterior power divided by \( n! \).

Suppose that \( Y \) is 1-dimensional. Then it is well known (cf, see [31]) that
\[
\tau^{n+1} = c(\tau) \cdot \tau^n \wedge \sqrt{-1} ds \wedge d\bar{s}.
\]
It follows that if \( c(\tau) > 0 \geq 0 \), then \( \tau \) is a positive (semi-positive) real \((1,1)\)-form as \( \tau \) is positive definite when restricted to \( X_y \). On the other hand, (2.3) says that
\[
p_\ast \tau^{n+1} = \int_{X_y} \tau^{n+1} = \int_{X_y} c(\tau) \cdot \tau^n \wedge \sqrt{-1} ds \wedge d\bar{s}.
\]
Hence \( p_\ast \tau^{n+1} \) is positive or semi-positive if and only if \( \int_{X_y} c(\tau) \tau^n \) is positive or nonnegative, respectively. For later use, we introduce the following lemma.

**Lemma 2.4.** The following identity holds:
\[
i_v \tau = \sqrt{-1} c(\tau) d\bar{s}.
\]

**Proof.** The computation is quite straightforward.
\[
i_v \tau = \sqrt{-1} \left( \tau_{\alpha \beta} d\bar{s} \tau_{\alpha \beta} \partial \partial_{\bar{z}} \alpha \right) = \sqrt{-1} \left( \tau_{\alpha \beta} d\bar{s} - \tau_{\alpha \beta} \partial \partial_{\bar{z}} \alpha \right) = \sqrt{-1} c(\tau) d\bar{s}.
\]
This completes the proof. \( \Box \)

2.2. **Kodaira-Spencer classes and Direct image bundles.** Let \( p : X \to Y \) be a smooth family of compact Kähler manifolds. We denote the Kodaira-Spencer map for the family \( p : X \to Y \) at a given point \( y \in Y \) by
\[
K_y : T'_y Y \to H^1(X_y, T'_X y).
\]
The Kodaira-Spencer map is induced by the edge homomorphism for the short exact sequence
\[
0 \to T'_X Y \to T'X \to p^\ast T'Y \to 0.
\]
If \( V \in T'_y Y \) is a tangent vector, and if
\[
V + b^\alpha \frac{\partial}{\partial z^\alpha}
\]
is any smooth lifting of \( V \) along \( X_y \), then
\[
\bar{\partial} \left( V + b^\alpha \frac{\partial}{\partial z^\alpha} \right) = \frac{\partial b^\alpha}{\partial z^\beta} \frac{\partial}{\partial z^\alpha} \otimes dz^\beta
\]
is a \( \bar{\partial} \)-closed form on \( X \), which represents \( K_y(V) \), i.e.,
\[
K_y(V) = \left[ \frac{\partial b^\alpha}{\partial z^\beta} \frac{\partial}{\partial z^\alpha} \otimes dz^\beta \right] \in H^{0,1}(X_y, T'_X y).
\]
This cohomology class \( K_y(V) \) is called the **Kodaira-Spencer class** of \( V \). The celebrated theorem of Kodaira and Spencer says that if the Kodaira-Spencer class vanishes locally, then the family is locally trivial ([20], see also [19]).
The direct image sheaf $E := p_* (K_{X/Y})$ of $K_{X/Y}$ is defined by the sheaf over $Y$ whose fiber $E_y$ is given by

$$E_y = H^0(X_y, K_{X_y}).$$

It is remarkable to note that this sheaf is indeed a holomorphic vector bundle by the Ohsawa-Takegoshi extension theorem (for more details, see Section 4 in \[4\]). $E$ is a hermitian vector bundle with $L^2$ metric defined by following: For $u_y, v_y \in E_y$, define $\langle u_y, v_y \rangle$ by

$$\langle u_y, v_y \rangle^2_y = \int_{X_y} c_n u_y \wedge \overline{v_y}$$

where $c_n = (\sqrt{-1})^n$ chosen to make the form positive. The Kodaira-Spencer class acts on $u_y \in E_y$ as follows: Let $k_y(V)$ be any representative of $K_y(V)$, i.e., $T'X_y$-valued $(0, 1)$-form in $K_y(V)$, which locally decomposes as

$$k_y = \zeta \otimes w$$

where $\zeta$ is a $(0, 1)$-form and $w$ is a vector field of type $(1, 0)$. Then $k_y(V)$ acts on $u_y$ by

$$k_y(V) \cdot u_y = \zeta \wedge (iw(u_y)),$$

where $iw$ is the contraction. This gives a globally defined $\bar{\partial}$-closed form of type $(n−1, 1)$ and

$$K_y(V) \cdot u_y := [k_y(V) \cdot u_y] \in H^{n−1,1}(X_y).$$

The following theorem due to Griffiths says the curvature of $E$ is computed in terms of Kodaira-Spencer classes (\[15\], see also \[5\]).

**Theorem 2.5.** Let $\Theta(E)$ be the curvature of $E$ with $L^2$-metric. Then for $V \in T'_y Y$,

$$\langle \Theta_{V \bar{\partial}}(E)u, u \rangle = \|K_y(V) \cdot u\|^2,$$

where $\|K_y(V) \cdot u\|$ is the norm of its unique harmonic representative. It does not depend on the choice of Kähler metric.

3. **Approximations of complex Monge-Ampère equations**

In this section, we discuss approximations of a solution of complex Monge-Ampère equation (1.3) in terms of the solutions of (1.2). First we consider the approximation on a single compact Kähler manifold. After that, we apply the approximation procedure to a family of complex Monge-Ampère equations. First, we recall the existence and uniqueness theorem of complex Monge-Ampère equations due to Aubin and Yau.

Let $(X, \omega)$ be a compact Kähler manifold. Let $f$ be a smooth function on $X$. The complex Monge-Ampère equation is given by the following:

$$(\omega + dd^c \varphi)^n = e^{\lambda \varphi + f} \omega^n,$$

$$(\omega + dd^c \varphi) > 0.$$
1. (Aubin/Yau) If $\lambda > 0$, then there exists a unique smooth function $\varphi$ satisfying (3.1) for every smooth function $f \in C^\infty(X)$.

2. (Yau) If $\lambda = 0$, then there exists a smooth function $\varphi$ satisfying (3.1) for $f \in C^\infty(X)$ such that $\int_X e^f \omega^n = \int_X \omega^n$. Moreover, the solution is unique up to the addition of constants.

3.1. Approximation on a compact Kähler manifold. Let $(M,\omega)$ be a compact Kähler manifold and $f$ be a smooth function on $M$ satisfying

$$\int_M e^f \omega^n = \int_M \omega^n.$$ 

Consider the following complex Monge-Ampère equation:

$$\left(\omega + dd^c \varphi\right)^n = e^f \omega^n,$$

$$\omega + dd^c \varphi > 0.$$ 

By Theorem 3.1, we already know that there exists a solution which is unique up to addition of constants.

Let $\{f_\varepsilon\}$ be a sequence of smooth functions in $M$ which converges to $f$ as $\varepsilon$ goes to 0 in $C^{k,\alpha}(M)$-topology for any $k \in \mathbb{N}$ and $\alpha \in (0,1)$. We want to approximate a solution of (3.6) by the solutions $\varphi_\varepsilon$ of the following complex Monge-Ampère equations:

$$\left(\omega + dd^c \varphi_\varepsilon\right)^n = e^{\varepsilon \varphi_\varepsilon + f_\varepsilon} \omega^n$$

$$\omega + dd^c \varphi_\varepsilon > 0,$$

as $\varepsilon \to 0$. Note that if $\varepsilon \to 0$, then Equation (3.3) converges to Equation (3.6).

The convention all over this paper is that we will use the same letter “$C$” to denote a generic constant, which may change from one line to another, but it is independent of the pertinent parameters involved (especially $\varepsilon$).

**Proposition 3.2.** For each $\varepsilon$ with $0 < \varepsilon \leq 1$, let $\varphi_\varepsilon$ be the solution of (3.3). Then for any $k \in \mathbb{N}$ and $\alpha \in (0,1)$, there exists a constant $C > 0$ which depend only on $k$, $\alpha$, the geometry of $(M,\omega)$ and the function $f$ such that

$$\|\varphi_\varepsilon\|_{C^{k,\alpha}(M)} < C.$$

In particular, $\{\varphi_\varepsilon\}$ is a relatively compact subset of $C^{k,\alpha}(M)$ for any positive integer $k$ and $\alpha \in (0,1)$.

**Proof.** We may assume that

$$\text{Vol}(M) = \int_X \omega^n = 1.$$

The first step is obtaining a uniform upper bound for $\varphi_\varepsilon$. For each $\varepsilon > 0$, the solution $\varphi_\varepsilon$ of (3.3) satisfies that

$$1 = \int_M \left(\omega + dd^c \varphi_\varepsilon\right)^n = \int_M e^{\varepsilon \varphi_\varepsilon + f_\varepsilon} \omega^n$$

Then Jensen inequality implies that

$$1 \geq \exp \left(\int_M \varepsilon \varphi_\varepsilon e^{f_\varepsilon} \omega^n\right),$$
it is equivalent to
\[ \int_M \varphi e^{\int \omega} \leq 0. \]
Note that \( f_\varepsilon \) converges to \( f \) as \( \varepsilon \to 0 \). The Hartogs lemma for quasi-plurisubharmonic functions implies that
\[ \sup_M \varphi_\varepsilon < C, \]
where \( C \) is a constant which depends only on the geometry of \((M, \omega)\) and \( f \) ([15]).
Here we recall the simple version of Kołodziej’s uniform estimates (for the general theorem, see [21, 22]).

**Theorem 3.3.** Let \((M, \omega)\) be a compact Kähler manifold. Assume that \( \varphi \) satisfies the following complex Monge-Ampère equation:
\[ (\omega + dd^c \varphi)^n = F \omega^n, \]
\[ \omega + dd^c \varphi > 0. \]
Then
\[ \|\varphi\|_{C^0(M)} \leq C \]
where \( C > 0 \) depends only on \((M, \omega)\) and on an upper bound for \( \|F\|_p \) for some \( 1 < p \leq \infty \).

If we set \( F = e^{\varepsilon \varphi + f_\varepsilon} \), then \( |F| < C \) for some \( C > 0 \) by (3.4). Then it follows from Theorem 3.3 that
\[ \|\varphi_\varepsilon\|_{C^0(M)} < C \]
for some \( C > 0 \) which depends only on \( M \) and the function \( f \).

The second step is obtaining the Laplacian estimates. We recall the following theorem in [12], which is essentially due to M. Păun ([27], cf. see [32]).

**Theorem 3.4.** Let \( \psi^+ \) and \( \psi^- \) be smooth quasi-plurisubharmonic functions on \( M \). Let \( \varphi \in C^\infty(M) \) be such that \( \sup_M \varphi = 0 \) and
\[ (\omega + dd^c \varphi)^n = e^{\psi^+-\psi^-} \omega^n. \]
Assume given a constant \( C > 0 \) such that
\[ dd^c \psi^+ \geq -C \omega, \quad \sup_M \psi^+ \leq C. \]
Assume also that the holomorphic bisectional curvature of \( \omega \) is bounded from below by \(-C\). Then there exists \( A > 0 \) depending on \( C \) and \( \int_M e^{-2(4C+1)^2n} \omega^n \) such that
\[ 0 \leq n + \Delta \omega \varphi \leq Ae^{-2\psi^-}. \]
We take \( \psi^+ = \varepsilon \varphi + f_\varepsilon \) and \( \psi^- = 0 \). Since \( f_\varepsilon \) converges to \( f \) as \( \varepsilon \to 0 \) and every \( \varphi_\varepsilon \) satisfies that
\[ dd^c \varphi_\varepsilon > -\omega, \]
it follows from (3.5) that \( \psi^+ \) satisfies the hypothesis of Theorem 3.4. Note that \( \{\varphi_\varepsilon\}_{0 < \varepsilon \leq 1} \) is a relatively compact subset of \( L^1(X, \omega) \). This implies the Laplacian estimates for \( \varphi_\varepsilon \):
\[ |\Delta \omega \varphi_\varepsilon| < C \]
for some constant \( C > 0 \) which depends only on the geometry of \((M, \omega)\) and the function \( f \) by the Uniform Skoda Integrability Theorem due to Zeriahi ([33]).
The final step is $C^{2,\alpha}(M)$-estimate. For $k \geq 2$ and $\alpha \in (0,1)$, the standard Evans-Krylov method ([13, 23]) and Schauder estimates (cf, see [2, 17]) imply

$$\|\varphi_\varepsilon\|_{C^{k,\alpha}(X)} \leq C,$$

where $C$ is a positive constant which depends only on $k, \alpha$, the geometry of $(M, \omega)$ and the function $f$. This completes the proof. $\square$

Proposition 3.2 implies that there exists a $\hat{\varphi} \in C^\infty(M)$ such that $\varphi_\varepsilon \to \hat{\varphi}$ as $\varepsilon \to 0$ by passing through a subsequence. However, $\varphi_\varepsilon$ converges without choosing a subsequence.

**Corollary 3.5.** The solution $\varphi_\varepsilon$ converges to $\varphi$ which satisfies the following normalization condition

$$\int_M \varphi e^f \omega^n = 0.$$

**Proof.** Consider the following complex Monge-Ampère equation:

$$(\omega + dd^c \varphi)^n = e^f \omega^n,$$

$$\omega + dd^c \varphi > 0.$$  \hspace{1cm} (3.6)

By Theorem 3.1 we already know that there exists a solution which is unique up to addition of constants. Let $\varphi_0$ be the unique solution which satisfies that

$$\int_M \varphi_0 e^f \omega^n = 1.$$

For $0 < \varepsilon \leq 1$, we consider the following equation:

$$(\omega + dd^c \varphi_\varepsilon)^n = e^{\varepsilon \varphi_\varepsilon + f} \omega^n,$$

$$\omega + dd^c \varphi_\varepsilon > 0.$$ \hspace{1cm} (3.7)

Now we want to show that $\varphi_\varepsilon \to \varphi_0$ in $C^{k,\alpha}(X)$-topology. It is enough to show that

$$\lim_{\varepsilon \to 0} \int_M \varphi_\varepsilon e^f \omega^n = 0.$$

By Kolodziej’s estimate, there exists a uniform constant $C > 0$ such that

$$\|\varphi_\varepsilon\|_{C^{k,\alpha}(M)} < C.$$

It follows that

$$e^{\varepsilon \varphi_\varepsilon} = 1 + \varepsilon \varphi_\varepsilon + o(\varepsilon).$$

On the other hand, we have

$$1 = \int_M \omega^n = \int_M (\omega + dd^c \varphi_\varepsilon)^n = \int_M e^{\varepsilon \varphi_\varepsilon} e^f \omega^n = \int_M (1 + \varepsilon \varphi_\varepsilon + o(\varepsilon)) e^f \omega^n,$$

so we have

$$\varepsilon \int_M \varphi_\varepsilon e^f \omega^n = o(\varepsilon) \int_X e^f \omega^n.$$

This implies the conclusion. $\square$
3.2. **Approximation on a family of complex Monge-Ampère equations.** Let $p : X^{n+d} \rightarrow Y^d$ be a smooth family of compact Kähler manifolds and $\omega$ be a fixed Kähler form on $X$. Let $\xi$ be a differential form of degree $2n + r$ on $X$. Then the fiber integral is a differential form of degree $r$ on $Y$, which is defined as follows: Fix a point $y \in Y$ and let $(U, s = (s^1, \ldots, s^d))$ be a coordinate centered at $y$ such that there exists a $C^\infty$ trivialization of the family:

$$
\Phi : X_0 \times U \rightarrow p^{-1}(U).
$$

In an admissible coordinate $(z, s)$, the pull-back $\Phi^* \xi$ is of the form

$$
\sum \xi_k(z, s) dV_z \wedge d\sigma^1 \wedge \cdots \wedge d\sigma^r,
$$

where the $\sigma^k$ run through the real and imaginary parts of $s^j$ and $dV_z$ denotes the relative Euclidean volume form. Now the fiber integral is defined by

$$
\int_{X/Y} \xi = \int_{X_0 \times Y/Y} \Phi^* \xi = \sum \left( \int_{X_s} \xi_k(z, s) dV_z \right) d\sigma^1 \wedge \cdots \wedge d\sigma^r.
$$

Note that this definition is independent of the choice of coordinates and differentiable trivializations. The fiber integral coincides with the push-forward of the corresponding current. Hence, if $\xi$ is a differentiable form of type $(n + r, n + s)$, then the fiber integral is of type $(r, s)$. In particular, if $\xi$ be a differentiable form of type $(n, n)$ on $X$, then $\int_{X_s} \xi$ is a smooth function on $Y$. Moreover, we have the following properties (for the details, see [30]):

(i) Fiber integration coincides with the push forward of a form, which is defined as follows: For a form $\xi$ on $X$, $p_* \xi$ is defined by the form on $Y$ which satisfies

$$
\int_Y (p_* \xi) \wedge \zeta = \int_X \xi \wedge (p^* \zeta)
$$

for any form $\zeta$ on $Y$.

(ii) Fiber integration commutes with taking exterior derivatives:

$$
d \int_X \xi = \int_X d\xi
$$

(iii) For a smooth form $\xi$ of type $(n, n)$,

$$
\frac{\partial}{\partial s^i} \int_X \xi = \int_X L_V(\xi)
$$

for any smooth lifting $V$ of $\partial/\partial s^i$ on $X$.

Note that the volume of a fiber does not change, namely, (ii) implies that

$$
d \operatorname{Vol}_{\omega|X_s}(X_s) = d \int_{X_s} \omega^n = \int_{X_s} d\omega^n = 0.
$$

Hence we may assume that $\operatorname{Vol}_{\omega|X_y}(X_y) = 1$ for every $y \in Y$. The third property (iii) will be used in Section 6.

From now on, we consider a smooth family $p : X \rightarrow D$ of compact Kähler manifolds over the unit disc $D$ in $\mathbb{C}$. Let $\omega$ be a Kähler form on $X$. Under an admissible coordinate $(z^1, \ldots, z^n, s)$ in $X$, $\omega$ is written as follows:

$$
\omega = \sqrt{-1} \left( g_{s\bar{s}} ds \wedge d\bar{s} + g_{s\bar{\beta}} d\bar{s} \wedge dz^\beta + g_{\alpha s} dz^\alpha \wedge d\bar{s} + g_{\alpha \bar{\beta}} dz^\alpha \wedge dz^\beta \right).
$$
For $0 < \varepsilon \leq 1$, let $\{f_\varepsilon\}$ be a sequence of smooth functions on $X$. We consider the following fiberwise complex Monge-Ampère equations:

$$
(\omega_y + dd^c \varphi_y)^n = e^{\varepsilon \varphi_y + f_\varepsilon |_{X_y}} (\omega_y)^n, \\
\omega_y + dd^c \varphi_y > 0
$$
on $X_y$ for $y \in D$. Theorem 3.1 implies that for each $y$, there exists a unique solution of (3.9), call it $\varphi_{y,\varepsilon} \in C^\infty(X_y)$. It is remarkable to note that the function $\varphi_\varepsilon$ defined by

$$
\varphi_\varepsilon(x) = \varphi_{y,\varepsilon}(x),
$$
where $y = p(x)$, is a smooth function on $X$. This follows from the openness analysis of the continuity method for complex Monge-Ampère equations and the implicit function theorem ([38]). By Section 3.1, there exists a constant $C_y > 0$ such that

$$
\|\varphi_\varepsilon\|_{C^{k,\alpha}(X_y)} \leq C_y
$$
where $C_y$ does not depend on $\varepsilon$. Since we are now considering a local property on $y$, we may assume that $C = C_y$ does not depend on $y$.

In this section, we consider the $C^{k,\alpha}$-estimates for $V \varphi_\varepsilon$ and $\bar{V} V \varphi_\varepsilon$ on a fixed fiber $X_y$, where $V$ is any smooth lifting of $\partial/\partial s$ written as follows:

$$
V = \frac{\partial}{\partial s} + a_s \gamma \frac{\partial}{\partial z^\gamma}.
$$
Before going further, we introduce the following proposition.

**Proposition 3.6.** Let $(X, \omega)$ be a compact Kähler manifold. Let $\{\rho_\varepsilon\}_{\varepsilon \in I}$ be a family of Kähler metrics on $X$ which are uniformly equivalent to $\omega$, i.e., there exists a constant $C_1 > 0$ such that

$$
\frac{1}{C_1} \omega < \rho_\varepsilon < C_1 \omega \quad \text{for all} \quad \varepsilon \in I.
$$
Let $u_\varepsilon$ be a solution of the following PDE:

$$
-\Delta_{\rho_\varepsilon} u_\varepsilon + \varepsilon u_\varepsilon = R_\varepsilon,
$$
where $R_\varepsilon$ is a smooth function on $X$ with

$$
\|R_\varepsilon\|_{C^{k,\alpha}(X)} < C_2.
$$
Suppose that

$$
\left| \int_X u_\varepsilon \omega^n \right| < C_3.
$$
Then there exists a uniform constant $C > 0$ which depends only on $C_1$, $C_2$, $C_3$ and the geometry of $(X, \omega)$ such that

$$
\|u_\varepsilon\|_{C^{k,\alpha}(X)} < C.
$$

**Proof.** In this proof, we shall use the Schauder estimate, Poincaré inequality and Sobolev inequality with respect to the Kähler metric $\rho_\varepsilon$ (cf, see [17][2]). It is remarkable to note that the constants in those inequalities do not depend on $\varepsilon \in I$ since all $\rho_\varepsilon$ are uniformly equivalent to $\omega$. If we have the uniform estimate, i.e., $C^0$-estimates of $u$, then Schauder estimate completes the proof.
The Poincaré inequality says that there exists a constant $C$ which depends only on $C_1$ and the geometry of $(M, \omega)$ such that
\[
\left\| u_\varepsilon - \int_X u_\varepsilon \rho_\varepsilon^n \right\|_{L^2_{\rho_\varepsilon}(X)} < C \| Du_\varepsilon \|_{L^2_{\rho_\varepsilon}(X)},
\]
where $D$ is a total derivative. It follows from the assumption that
\[
\| u_\varepsilon \|_{L^2_{\rho_\varepsilon}(X)} < C \| Du_\varepsilon \|_{L^2_{\rho_\varepsilon}(X)} + C_1 C_3.
\]
On the other hand, multiplying $u_\varepsilon$ to (3.11) and integrating it with respect to $(\rho_\varepsilon)^n$, we have
\[
\| Du_\varepsilon \|_{L^2_{\rho_\varepsilon}(X)}^2 + \varepsilon \| u_\varepsilon \|_{L^2_{\rho_\varepsilon}(X)}^2 = \int_X R_\varepsilon u_\varepsilon \rho_\varepsilon^n.
\]
The Hölder inequality says that
\[
\| Du_\varepsilon \|_{L^2_{\rho_\varepsilon}(X)}^2 \leq \| R_\varepsilon \|_{L^2_{\rho_\varepsilon}(X)} \| u_\varepsilon \|_{L^2_{\rho_\varepsilon}(X)}
\]
Combining the two equations, there exists a uniform constant $C$ which depends only on $C_1, C_2, C_3$ and the geometry of $(X, \omega)$ such that
\[
\| u_\varepsilon \|_{L^2_{\rho_\varepsilon}(X)} < C.
\]
Now we follow the Moser iteration. Multiplying (3.16) by $|u_\varepsilon|^{2p-1} u_\varepsilon / |u_\varepsilon|$ and integrating it, we have
\[
\frac{2p-1}{p} \int_X |D|u_\varepsilon|p|^{2} \omega^n + \varepsilon \int_X |u_\varepsilon|^{2p} \omega^n = \int_X R_\varepsilon u_\varepsilon \omega^n.
\]
The Sobolev inequality says that
\[
\| |u_\varepsilon|^{p} \|_{L^{2p/(n-1)}_{\rho_\varepsilon}(X)} \leq C \left( \| u_\varepsilon \|_{L^2_{\rho_\varepsilon}(X)} + \| D|u_\varepsilon|^{p} \|_{L^2_{\rho_\varepsilon}(X)} \right)
\]
for $p \geq 1$ ([2]). Combining two equations, we have
\[
\| u_\varepsilon \|_{L^p_{\rho_\varepsilon}(X)} \leq (Cp)^{1/p} \| u_\varepsilon \|_{L^p_{\rho_\varepsilon}(X)}
\]
for $p \geq 1$. The uniform estimate is obtained by the Moser iteration method (cf, see [17]). Indeed, set
\[
p_1 = 1, \quad p_k = \left( \frac{n}{n-1} \right)^k.
\]
Then it follows that
\[
\| u \|_{L^\infty(X)} = \lim_{k \to \infty} \| u_\varepsilon \|_{L^{2p_k}_{\rho_\varepsilon}(X)} \leq \prod_{k=1}^{n} (Cp_k)^{1/p_k} \| u_\varepsilon \|_{L^2_{\rho_\varepsilon}(X)}.
\]
This completes the proof. \hfill \Box

**Proposition 3.7.** Suppose that there exist constants $C_1 > 0$ and $C_2 > 0$ such that
\[
\left| \int_X (V \varphi_\varepsilon)(\omega_\eta)^n \right| < C_1
\]
and
\[
\| Vf_\varepsilon \|_{C^{k, \alpha}(X, \eta)} < C_2.
\]
Then there exists a constant $C$ which depends only on the constants $C_1$, $C_2$, the lift $V$ and the geometry of $(X_y, \omega_y)$ such that

$$\|V \varphi_\varepsilon\|_{C^{k,\alpha}(X_y)} < C$$

for $0 < \varepsilon \leq 1$. In particular, $\{V \varphi_\varepsilon\}_{0 < \varepsilon \leq 1}$ is a relatively compact subset in $C^{k,\alpha}(X_y)$ for any $k \in \mathbb{N}$ and $\alpha \in (0,1)$.

**Proof.** We denote by $\rho_\varepsilon = \omega + dd^c \varphi_\varepsilon$. Note that Proposition 3.2 implies that there exists a uniform constant $C > 0$ such that

$$\frac{1}{C} \omega_y < \rho_\varepsilon|_{X_y} < C \omega_y,$$

for $0 < \varepsilon \leq 1$. Under an admissible coordinate $(z^1, \ldots, z^n, s)$, the first equation of (3.14) is written as follows:

$$\det(g_{\alpha \beta} + (\varphi_\varepsilon)_{\alpha \beta}) = e^{\varepsilon \varphi_\varepsilon + f_\varepsilon} \det(g_{\alpha \beta})$$

on each $X_y$. Taking logarithm of (3.14) and differentiating it with respect to $V$, we have

$$(\rho_\varepsilon)^{\alpha \beta} V(g_{\alpha \beta} + (\varphi_\varepsilon)_{\alpha \beta}) = \varepsilon V \varphi_\varepsilon + V f_\varepsilon + g^{\alpha \beta} V(g_{\alpha \beta}).$$

For a smooth function $\xi$, we denote by

$$[V, \xi]_{\alpha \beta} = V(\xi_{\alpha \beta}) - (V \xi)_{\alpha \beta}$$

$$= -a_s^{\gamma} g_{\alpha \beta} \xi_\gamma - a_s^{\gamma} \xi_{\alpha \beta} - a_s^{\gamma} \xi_\beta \xi_\alpha.$$

It is remarkable to note that $[V, \xi]_{\alpha \beta}$ does not include $s$-derivative of $\xi$. Then it follows that

$$-\Delta_{\rho_\varepsilon|_{X_y}} (V \varphi_\varepsilon) + \varepsilon (V \varphi_\varepsilon) = - V f_\varepsilon - g^{\alpha \beta} V(g_{\alpha \beta})$$

$$+ (\rho_\varepsilon)^{\alpha \beta} (V(g_{\alpha \beta}) + [V, \varphi_\varepsilon]_{\alpha \beta})$$

on each fiber $X_y$, where $\Delta_{\rho_\varepsilon|_{X_y}}$ is the Laplace-Beltrami operator on $X_y$ with respect to $\rho_\varepsilon|_{X_y}$. Here $(V \varphi_\varepsilon)$ and $(V f_\varepsilon)$ mean that

$$V \varphi_\varepsilon = (V \varphi_\varepsilon)|_{X_y} \quad \text{and} \quad V f_\varepsilon = (V f_\varepsilon)|_{X_y}.$$

From now on, when we think about a family of PDEs, we omit the subscript $X_y$ in the Laplace-Beltrami operator, i.e., we write as follows:

$$\Delta_{\rho_\varepsilon} = \Delta_{\rho_\varepsilon|_{X_y}}.$$

Equation (3.15) says that the right hand side of (3.13) is a globally defined function on $X_y$, call it $R_\varepsilon$. Then we have

$$-\Delta_{\rho_\varepsilon} (V \varphi_\varepsilon) + \varepsilon (V \varphi_\varepsilon) = R_\varepsilon.$$ 

This is a second order elliptic partial differential equation with the hypotheses in Proposition 3.6. This completes the proof. \qed

**Proposition 3.8.** Under the assumption in Proposition 3.7, suppose that there exists a constant $C_3 > 0$ and $C_4$ such that

$$\left| \int_{X_y} \left(\bar{V} (V \varphi_\varepsilon) (\omega_y)^n \right) \right| < C_3$$

and

$$\left\| \bar{V} f_\varepsilon \right\|_{C^{k,\alpha}(X_y)} < C_4.$$
Then there exists a constant $C$ which depends only on constants $C_1, C_2, C_3, C_4$, the lift $V$ and the geometry of $(X_y, \omega_y)$ such that

$$\|\bar{\nabla}V\varphi_\epsilon\|_{C^{k,\alpha}(X_y)} < C$$

for $0 < \epsilon \leq 1$. In particular, $\{\bar{\nabla}V\varphi_\epsilon\}_{0<\epsilon\leq1}$ is a relatively compact subset in $C^{k,\alpha}(X_y)$ for any $k \in \mathbb{N}$ and $\alpha \in (0, 1)$.

**Proof.** Differentiating (3.16) with respect to $\bar{\nabla}$ for $0<\epsilon\leq1$, and several applications of this PDE.

By the first discussion of a partial differential equation which the geodesic curvature $c(\rho)$ satisfies and several applications of this PDE.

$$-\Delta_{\rho_x} (\bar{\nabla}V\varphi_\epsilon) + \epsilon (\bar{\nabla}V\varphi_\epsilon) = \bar{\nabla} \left( (\rho_x)^{\beta\alpha} \cdot (\bar{\nabla}V\varphi_\epsilon)_{\beta\alpha} + (\rho_x)^{\beta\alpha} [\bar{\nabla}, \bar{\nabla}V\varphi_\epsilon]_{\alpha\beta} + \bar{\nabla}(R_\epsilon) \right).$$

Since $\|\varphi_\epsilon\|_{C^{k,\alpha}(X_y)}$ and $\|\bar{\nabla}\varphi_\epsilon\|_{C^{k,\alpha}(X_y)}$ are bounded, the same argument in the proof of Proposition 3.7 says this PDE satisfies the hypotheses in Proposition 3.6. This completes the proof. \(\square\)

### 4. Fiberwise Ricci-flat metrics on Calabi-Yau fibrations

In this section, we discuss the properties of the fiberwise Ricci-flat metric $\rho$. We first discuss a partial differential equation which the geodesic curvature $c(\rho)$ satisfies and several applications of this PDE.

Let $p : X \to Y$ be a smooth family of Calabi-Yau manifolds and $\omega$ be a Kähler form on $X$. We write $\omega$ like as (3.8). Since every fiber $X_y$ is a Calabi-Yau manifold, the first Chern class $c_1(X_y)$ vanishes for each fiber $X_y$. Since $c_1(X_y)$ is represented by the Ricci form of $\omega_y$, we know that

$$[-dd^c \log \det(g_{\alpha\beta}(\cdot, y))] = 0.$$ 

By the $dd^c$-lemma, there exists a unique function $\eta_y \in C^{\infty}(X_y)$ such that

- $dd^c \eta_y = dd^c \log \det(g_{\alpha\beta})$ and
- $\int_{X_y} e^{\eta_y}(\omega_y)^n = \int_{X_y}(\omega_y)^n$.

For each $y \in Y$, there exists a unique solution $\varphi_y \in C^{\infty}(X_y)$ of the following complex Monge-Ampère equation on each fiber $X_y$:

$$(\omega_y + dd^c \varphi_y)^n = e^{\eta_y}(\omega_y)^n,$$

(4.1)

which is normalized by

$$\int_{X_y} \varphi_y e^{\eta_y}(\omega_y)^n = 0.$$

Then it is easy to see that $\omega_y + dd^c \varphi_y$ is the Ricci-flat Kähler metric on $X_y$. As we already mentioned, we can consider $\varphi$ as a smooth function on $X$ by letting $\varphi(x) = \varphi_y(x)$ where $y = p(x)$. Define a real $(1, 1)$-form $\rho$ on $X$ by

$$\rho = \omega + dd^c \varphi.$$

Since $e^{\eta_y}(\omega_y)^n = (\omega_{KE,y})^n$, this is the fiberwise Ricci-flat metric in Theorem 1.1.

Since every fiber $X_y$ is Calabi-Yau, $K_{X_y}$ is a trivial line bundle for every $y \in Y$. Hence the direct image bundle $E = p_* (K_{X/Y})$ is a line bundle over $Y$. Take an admissible coordinate system $(z^1, \ldots, z^n, s^1, \ldots, s^d)$ in $X$. Let $u$ be a local holomorphic section of $E$ over an open set $U \subset Y$. (Shrinking $U$ if necessary, $s = (s^1, \ldots, s^d)$ can
be considered as a local coordinate in $U$.) Since $E$ is a line bundle, the curvature of $(E, \|\cdot\|)$ is given by

$$\Theta(E) = -dd^c \log \|u\|_s.$$  

We say that $u$ is a representative of $u$ if $u$ is an $(n,0)$-form on $p^{-1}(U)$, such that $u$ restricts to $u_s$ on fibers $X_s$, i.e.,

$$\iota^*(u) = u_s$$  

where $\iota_s$ is the natural inclusion map from $X_s$ to $X$ (for more details, see [4, 5]). The representative is not uniquely determined, but any two representatives are differ from $ds \wedge v$ for some $(n-1,0)$-form $v$. Hence if we denote by $u \wedge \overline{u} \wedge dV_s := u \wedge \overline{u} \wedge dV_s$, where $dV_s = c_d \omega_s \wedge d\tilde{s}$, then it does not depend on the choice of the representative. Moreover, it also follows that

$$\|u\|^2_s = c_n \int_{X_s} u \wedge \overline{u} = c_n \int_{X_s} u \wedge \overline{u}$$  

for any representative $u$ of $u$. In terms of $u$, the function $\eta$ is written explicitly:

**Proposition 4.1.** On $p^{-1}(U)$, $\eta$ is written as follows:

$$\eta(z,s) = -\log \frac{\omega^n \wedge dV_s}{c_n u \wedge \overline{u} \wedge dV_s} - \log \|u\|^2_s.$$  

In particular, we have the following:

$$dd^c\eta = -\Theta_{K_{X/Y}} (K_{X/Y}) + \Theta(E).$$  

**Proof.** Let $u$ be a representative of $u$. Denote the right hand side of (1.2) by $\tilde{\eta}$. It is easy to show the following:

1. $\int_{X_s} e^{\tilde{\eta}}(\omega_s)^n = 1$.
2. $dd^c\tilde{\eta}|_{X_s} = -dd^c \log \det(g_{\alpha\beta})|_{X_s}$.

First we compute

$$\int_{X_s} e^{\tilde{\eta}}(\omega_s)^n = \int_{X_s} \left[ \exp \left( -\log \frac{\omega^n \wedge dV_s}{c_n u \wedge \overline{u} \wedge dV_s} - \log \|u\|^2_s \right) \right] (\omega_s)^n$$  

If we write $dz = dz^1 \wedge \cdots \wedge dz^n$, then

$$(\omega_s)^n = \det(g_{\alpha\beta}) c_n dz \wedge d\overline{z}$$ and $u|_{X_s} = \hat{u}(z,s)dz$  

for some local holomorphic function $\hat{u}(z,s)$. It follows that

$$\int_{X_s} e^{\tilde{\eta}}(\omega_s)^n = \int_{X_s} \exp \left( -\log \frac{\det(g_{\alpha\beta})}{c_n |\hat{u}(z,s)|^2} - \log \|u\|^2_s \right) (\omega_s)^n$$  

$$= \frac{1}{\|u\|^2_s} \int_{X_s} \frac{c_n |\hat{u}(z,s)|^2}{\det(g_{\alpha\beta})} \det(g_{\alpha\beta}) dz \wedge d\overline{z}$$  

$$= \frac{1}{\|u\|^2_s} c_n \int_{X_s} |\hat{u}(z,s)|^2 \det(g_{\alpha\beta}) dz \wedge d\overline{z}$$  

$$= \frac{1}{\|u\|^2_s} c_n \int_{X_s} \hat{u}(z,s) dz \wedge \overline{\hat{u}(z,s)}$$  

$$= \frac{1}{\|u\|^2_s} c_n \int_{X_s} u \wedge \overline{u} = 1.$$
This yields the first assertion. For the second assertion,
\[ dd^c \eta|_{X_s} = -dd^c \left( \log \frac{\omega^n \wedge dV_s}{c_n u \wedge \bar{u} \wedge dV_s} + \log \|u_s\|^2 \right) \bigg|_{X_s} \]
\[ = -dd^c \left( \log \det(g_{a\bar{b}}) + \log |\hat{u}(z, s)|^2 \right) \bigg|_{X_s} \]
\[ = -dd^c \log \det(g_{a\bar{b}})|_{X_s}. \]
For the second assertion,
\[ dd^c \eta = -dd^c \log \frac{\omega^n \wedge dV_s}{c_n u \wedge \bar{u} \wedge dV_s} - dd^c \log \|u_s\|^2 \]
\[ = -dd^c \log \frac{\det(g_{a\bar{b}}(c_n dz \wedge d\bar{z} \wedge dV_s)}{|\hat{u}(z, s)|^2} - dd^c \log \|u_s\|^2 \]
\[ = -dd^c \log \det (g_{a\bar{b}}(z, s)) + dd^c \log |\hat{u}(z, s)| - dd^c \log \|u_s\|^2 \]
\[ = -\Theta_{h^{e}_{X/Y}}(K_{X/Y}) + dd^c \log |\hat{u}(z, s)|^2 + \Theta(E) \]
\[ = -\Theta_{h^{e}_{X/Y}}(K_{X/Y}) + \Theta(E). \]
This completes the proof. \[ \square \]

Since \( \rho \) is positive-definite on each fiber, it induces a hermitian metric \( h^{e}_{X/Y} \) on \( K_{X/Y} \) as in Remark 2.3. The curvature of \( h^{e}_{X/Y} \) is computed by Proposition 4.1 as follows:
\[ \Theta_{h^{e}_{X/Y}}(K_{X/Y}) = dd^c \log (\rho^n \wedge \sqrt{-1} ds \wedge d\bar{s}) \]
\[ = dd^c \log ((\omega + dd^c \varphi)^n \wedge \sqrt{-1} ds \wedge d\bar{s}) \]
\[ = dd^c \log (e^n \omega^n \wedge \sqrt{-1} ds \wedge d\bar{s}) \]
\[ = dd^c \eta + \Theta_{h^{e}_{X/Y}}(K_{X/Y}) - dd^c \log \omega^n \wedge dV_s \]
\[ = -\Theta_{h^{e}_{X/Y}}(K_{X/Y}) + \Theta(E) \]
\[ = \Theta(E). \]

Here \( \Theta(E) \) means \( p^*\Theta(E) \). This formula enables us to compute the Laplacian of \( c(\rho) \) on each fiber \( X_y \):

**Theorem 4.2.** Let \( V \in T_y Y \). Then the following PDE holds on \( X_y \):
\[(4.3) \quad -\Delta p c(\rho)(V) = |\bar{\partial}V|_\rho^2 - \Theta_{\partial V}(E).\]

The computation is quite straight forward. Later, we will prove this for more general situation (See Theorem 5.1).

**Remark 4.3.** To show that \( p_*\rho^{n+1} \) is positive on \( Y \), it is enough to consider a Calabi-Yau fibration over the unit disc by the following:
1. Let \( \sigma_1 \) and \( \sigma_2 \) be real \((1,1)\)-forms on \( Y \). Suppose that
\[ p_*(\sigma_1|_{\mathbb{D}})^{n+1} \geq p_*(\sigma_2|_{\mathbb{D}})^{n+1} \]
for each holomorphic disc \( \gamma^{n+1} : \mathbb{D} \to Y \). Then we have \( p_*(\sigma_1)^{n+1} \geq p_*(\sigma_2)^{n+1} \) on \( X \).
2. Every computation concerning the positivity of \( p_*\rho^{n+1} \) is local in \( s \)-variable, which is a local coordinate in \( Y \).
Therefore we only consider a family of Calabi-Yau manifolds over the unit disc in $\mathbb{C}$ as long as we are interested in positivity properties of $p_\ast \rho^{n+1}$. In this case, (4.3) turns out to be

\begin{equation}
- \Delta \rho c(\rho) = |\bar{\partial}v_\rho|^2 - \Theta_{s\bar{s}}(E),
\end{equation}

where $v = \partial/\partial s$ and $\Theta_{s\bar{s}}(E) = \Theta(E)(v, \bar{v})$. As we mentioned in Section 2.1, the positivity of $p_\ast \rho^{n+1}$ is equivalent to $\int_{X_y} c(\rho) \rho^n > 0$.

**Remark 4.4.** In case of a family of canonically polarized compact complex manifolds $p : X \to D$, Schumacher have proved that the geodesic curvature $c(\tilde{\rho})$ of the form $\tilde{\rho}$, which is induced by the fiberwise Kähler-Einstein metrics of Ricci curvature $-1$, satisfies the following PDE:

\begin{equation}
- \Delta_\rho c(\tilde{\rho}) + c(\tilde{\rho}) = |\bar{\partial}v_{\tilde{\rho}}|^2
\end{equation}

for each fiber $X_y$ (30). This PDE gives a lower bound of $c(\tilde{\rho})$ directly by the maximum principle. (More precise lower bound is also obtained using heat kernel estimates by Schumacher.) Hence the fiberwise Kähler-Einstein form $\tilde{\rho}$ is a semi-positive metric on $X$. However (4.4) does not gives a lower bound by the maximum principle.

It is worthwhile to note that the Weil-Petersson metric on the moduli space of canonically polarized manifolds is expressed by the fiberwise Kähler-Einstein metric $\tilde{\rho}$. More precisely, it follows from (4.5) and (2.3) that the Weil-Petersson metric $\omega_{WP}$ is written by

\begin{equation}
\omega_{WP} = \int_{X_y} \tilde{\rho}^{n+1}.
\end{equation}

In case of the moduli space of polarized Calabi-Yau manifolds, our fiberwise Ricci-flat metric does not give such kind of identity. Recently, Braun proved that there exists a Kähler form $\omega_{SRF}$ on a family of polarized Calabi-Yau manifolds with vanishing first betti number such that the restriction of the Kähler form on each fiber is Ricci-flat metric and it satisfies (4.6) (7).

In the last of this section, we discuss some applications of Theorem 4.2. The Weil-Petersson form $\omega_{WP}$ of a family $p : X \to Y$ is a real $(1, 1)$-form on $Y$ which is induced by the following norm:

\begin{equation}
\|V\|_{WP}^2 = \int_{X_y} \|\bar{\partial}V_\rho\|^2 dV_\rho.
\end{equation}

**Proposition 4.5.** For $V \in T'Y$, the following holds:

\[ \|\bar{\partial}V_\rho\|^2_\rho = \Theta_{V \bar{V}}(E). \]

In particular, $\omega_{WP} = \Theta(E)$.

**Proof.** Integrating (4.3) on $X_y$ gives the conclusion. \qed

**Proposition 4.6.** $\bar{\partial}V_\rho \cdot u_y$ is the harmonic representative of the cohomology class $K_y(V) \cdot u_y$ with respect to $\rho|_{X_y}$.

**Proof.** Since $E$ is a line bundle, Griffiths’ theorem implies that

\[ \Theta_{V \bar{V}}(E) = \frac{\|K_y(V) \cdot u_y\|^2}{\|u_y\|^2}. \]
Note that
\[ \bar{\partial} V_\rho \in K_\omega(V). \]

It follows that
\[ \frac{\|K_\omega(V) \cdot u \|}{\|u \|^2} \leq \frac{\|\bar{\partial} V_\rho \cdot u \|^2}{\|u \|^2}. \]

The following lemma is well known (cf, see [29]).

**Lemma 4.7.** Let \((X, \omega)\) be a Calabi-Yau manifold. Let \(u\) be a non-vanishing holomorphic \(n\)-form on \(X\) such that
\[ \|u\|^2 := \int_X |u|^2 \, dV_\omega = \int_X dV_\omega = 1. \]

Denote by \(A^{(p,q)}(E)\) the space of smooth \((p,q)\)-forms with values in \(E\). Define a map
\[ T_u : A^{(0,1)}(T^*X) \to A^{(n-1,1)}(X) \]
by \(T_u(V) = V \cdot u\). Then \(T_u\) is an isometry with respect to the pointwise scalar product induced by \(\omega\).

Hence Proposition 4.4 implies that
\[ \|\bar{\partial} V_\rho \|^2 = \Theta_{V \bar{V}}(E) \leq \frac{\|K_\omega(V) \cdot u \|^2}{\|u \|^2} \leq \frac{\|\bar{\partial} V_\rho \cdot u \|^2}{\|u \|^2} = \|\bar{\partial} V_\rho \|^2. \]

It follows that \(\bar{\partial} V_\rho \cdot u\) is the harmonic representative with respect to \(\rho|_X\) of \(K_\omega(V) \cdot u\). This completes the proof. \(\square\)

**Proposition 4.8.** Let \(p : X \to Y\) be a Calabi-Yau fibration. If the curvature of the direct image bundle \(p_*(K_X/Y)\) vanishes along a complex curve, then the fibration is trivial along the complex curve.

**Proof.** Denote by \(\gamma\) the complex curve in \(Y\). Then \(p|_\gamma : X_\gamma \to \gamma\) is a Calabi-Yau fibration over a 1-dimensional base. If we take \(s\) be a holomorphic coordinate of \(\gamma\), then we have Equation (4.4) on each fiber \(X_y\) for \(y \in \gamma\). By the Hypothesis, \(\Theta_{s\bar{s}}(E)\) vanishes on \(\gamma\). Proposition 4.7 implies that \(v_\rho\) is a holomorphic vector field on \(X_\gamma\). The flow of \(v_\rho\) makes \(X_\gamma\) a trivial fibration. \(\square\)

5. PROOF OF THEOREM 1.1 AND THEOREM 1.2

In this section we shall prove the main theorem. As we mentioned in Remark 4.8, it is enough to show that \(\int_{X/D} e(\rho) \rho^n \geq 0\) for a family of Calabi-Yau manifolds over the unit disc in \(\mathbb{C}\).

Let \(p : X \to D\) be a smooth family of Calabi-Yau manifolds. For each \(\varepsilon\) with \(0 < \varepsilon \leq 1\), we consider the following fiberwise complex Monge-Ampère equation on each fiber \(X_y\):
\[ (\omega_y + dd^c \varphi_y)^n = e^{\varphi_y} e^{\eta_y} (\omega_y)^n \quad \text{and} \quad \omega_y + dd^c \varphi_y > 0, \]
(5.1)
where \(\eta\) is defined in Section 4. Theorem 3.1 implies that there exists a unique solution \(\varphi_{y,\varepsilon} \in C^\infty(X_y)\) of (5.1). As we mentioned, we can consider \(\varphi_\varepsilon\) as a smooth function on \(X\) by letting \(\varphi_\varepsilon(x) := \varphi_{y,\varepsilon}(x)\), where \(y = p(x)\). We consider next the (1,1)-form
\[ (\rho_\varepsilon := \omega + dd^c \varphi_\varepsilon, \]
(5.2)
on the manifold $X$. Since $\rho_\varepsilon$ is positive definite when restricted to $X_y$, it induces a hermitian metric $h^{\rho_\varepsilon}_{X/Y}$ on the bundle $K_{X/Y}|_{X_0}$. By Proposition 3.1 the curvature is computed as follows:

$$
\Theta_{h^{\rho_\varepsilon}_{X/Y}}(K_{X/Y}) = dd^c \log \left( (\rho_\varepsilon)^n \wedge \sqrt{-1} ds \wedge d\bar{s} \right)
$$

$$
= dd^c \log \left( (\omega + dd^c \varphi_\varepsilon)^n \wedge \sqrt{-1} ds \wedge d\bar{s} \right)
$$

$$
= dd^c \log \left( e^{\varepsilon \varphi_\varepsilon + \varepsilon \omega} \wedge \sqrt{-1} ds \wedge d\bar{s} \right)
$$

$$
= dd^c \eta + \varepsilon dd^c \varphi_\varepsilon + \Theta_{h^{\rho_\varepsilon}_{X/Y}}(K_{X/Y})
$$

$$
= \Theta(E) + \varepsilon dd^c \varphi_\varepsilon.
$$

From (5.2), we have $dd^c \varphi_\varepsilon = \rho_\varepsilon - \omega$, it follows that

$$
(5.3) \quad \Theta_{h^{\rho_\varepsilon}_{X/Y}}(K_{X/Y}) = \varepsilon \rho_\varepsilon - \varepsilon \omega + \Theta(E)
$$

in the other expression,

$$
\varepsilon \rho_\varepsilon = \varepsilon \omega + \Theta_{h^{\rho_\varepsilon}_{X/Y}}(K_{X/Y}) - \Theta(E).
$$

Our next claim is the geodesic curvature $c(\rho_\varepsilon)$ satisfies a certain elliptic partial differential equation of second order on each fiber $X_y$.

Under an admissible coordinate $(z^1, \ldots, z^n, s) \in X$, $\rho_\varepsilon$ is written as follows:

$$
\rho_\varepsilon = \sqrt{-1} \left( (h_\varepsilon)_{ss} ds \wedge d\bar{s} + (h_\varepsilon)_{s\bar{\alpha}} ds \wedge dz^\bar{\alpha} + (h_\varepsilon)_{s\alpha} dz^\alpha \wedge d\bar{s} + (h_\varepsilon)_{\bar{\alpha} \bar{\beta}} dz^{\bar{\alpha}} \wedge dz^{\bar{\beta}} \right).
$$

For each $y \in D$, $(h_\varepsilon)_{\alpha \bar{\beta}}(\cdot, y)$ gives a Kähler metric on $X_y$. (If there is no confusion, we simply write $(h_\varepsilon)_{\alpha \bar{\beta}}$.) Thus we can define contraction and covariant derivative on each $X_y$ with respect to $(h_\varepsilon)_{\alpha \bar{\beta}}$. We use raising and lowering of indices as well as the semi-colon for the contractions and the covariant derivatives with respect to the Kähler metric $(h_\varepsilon)_{\alpha \bar{\beta}}$, respectively, on the fiber $X_y$. We denote by $\Delta_{\rho_\varepsilon} = \Delta_{\rho_\varepsilon|X_y}$ the Laplace-Beltrami operator with negative eigenvalues on the fiber $X_y$ with respect to $\rho_\varepsilon|_{X_y}$.

By raising of indices, we can write the horizontal lift $v_{\rho_\varepsilon}$ of $v = \partial/\partial s$ with respect to $\rho_\varepsilon$ by

$$
v_{\rho_\varepsilon} = \frac{\partial}{\partial s} - (h_\varepsilon)_{s\bar{\alpha}} \frac{\partial}{\partial z^{\bar{\alpha}}} = \frac{\partial}{\partial s} - (h_\varepsilon)_{s\alpha} \frac{\partial}{\partial z^\alpha}.
$$

Then $\bar{\partial} v_{\rho_\varepsilon}$ is a $T'X_y$-valued $(0, 1)$-form which is defined by

$$
\bar{\partial} v_{\rho_\varepsilon} = \bar{\partial} \left( \frac{\partial}{\partial s} - (h_\varepsilon)^{s\alpha} \frac{\partial}{\partial z^\alpha} \right)
$$

$$
= - (\bar{\partial} (h_\varepsilon)^{s\alpha}) \otimes \frac{\partial}{\partial z^\alpha}
$$

$$
= - (h_\varepsilon)^{s\alpha} \frac{\partial}{\partial z^\beta} \otimes \frac{\partial}{\partial z^{\bar{\alpha}}}.
$$

Since $(h_\varepsilon)_{\alpha \bar{\beta}}$ is a Kähler metric and we use holomorphic coordinates, $\bar{\partial} v_{\rho_\varepsilon}$ is written by

$$
\bar{\partial} v_{\rho_\varepsilon} = -(h_\varepsilon)_{s\alpha} \frac{\partial}{\partial z^{\bar{\alpha}}} \otimes \frac{\partial}{\partial z^\alpha}.
$$
Then Remark 2.2 says that the geodesic curvature \( c(\rho_\varepsilon) : X \to \mathbb{R} \) is given by
\[
c(\rho_\varepsilon)(z, s) = \langle v_{\rho_\varepsilon}, v_{\rho_\varepsilon} \rangle_{\rho_\varepsilon}
= (h_\varepsilon)_{s\bar{s}} - (h_\varepsilon)_{s\bar{\beta}}(h_\varepsilon)_{\bar{\beta}a}(h_\varepsilon)_{a\bar{s}}.
\]
The following theorem is inspired by Schumacher’s method in [30]. Pǎun generalized the computation to the twisted Kähler-Einstein metric case ([28]). (See also [9].)

**Theorem 5.1.** The following partial differential equation holds on each fiber \( X_y \):
\[
-\Delta_{\rho_\varepsilon} c(\rho_\varepsilon) + \varepsilon c(\rho_\varepsilon) = \varepsilon \omega(v_{\rho_\varepsilon}, \overline{v_{\rho_\varepsilon}}) + |\overline{\partial v_{\rho_\varepsilon}}|^2_{\rho_\varepsilon} - \Theta_{ss}(E),
\]
where \( |\overline{\partial v_{\rho_\varepsilon}}|_{\rho_\varepsilon} \) is the pointwise norm of \( \overline{\partial v_{\rho_\varepsilon}} \) with respect to the Kähler metric \( \rho_\varepsilon|_{X_y} \).

**Proof.** We fix a fiber \( X_y \) and \( \varepsilon > 0 \). During this proof, if there is no confusion, we omit the subscript \( \varepsilon \) in the components in \( \rho_\varepsilon \) for simplicity, namely, we write as follows:
\[
h_{s\bar{s}} = (h_\varepsilon)_{s\bar{s}}, \quad h_{s\bar{\beta}} = (h_\varepsilon)_{s\bar{\beta}} \quad \text{and} \quad h_{\alpha\bar{\beta}} = (h_\varepsilon)_{\alpha\bar{\beta}}.
\]
We have to compute the following:
\[
\Delta_{\rho_\varepsilon} c(\rho_\varepsilon) = h^\delta\gamma(c(\rho_\varepsilon))_{\gamma\delta} = h^\delta\gamma \left( h_{s\bar{s}} - h_{s\bar{\beta}}h^{\bar{\beta}a}h_{a\bar{s}} \right)_{\gamma\delta}.
\]
First we consider the term \( h^\delta\gamma h_{s\bar{s}\gamma\delta} \). Since \( \omega \) is a Kähler form on \( X \), \( \rho_\varepsilon \) is locally \( \partial\bar{\partial} \)-exact. So we have that
\[
h_{s\bar{s}\gamma\delta} = \frac{\partial^2 h_{s\bar{s}}}{\partial z^\gamma \partial \bar{z}^\delta} = \frac{\partial^2}{\partial s \partial \bar{s}} h_{\gamma\delta}.
\]
Then it follows that
\[
h^\delta\gamma h_{s\bar{s}\gamma\delta} = h^\delta\gamma \frac{\partial^2}{\partial s \partial \bar{s}} h_{\gamma\delta}
= \frac{\partial}{\partial s} \left( h^\delta\gamma \frac{\partial}{\partial \bar{s}} h_{\gamma\delta} \right) - \frac{\partial h^\delta\gamma}{\partial s} \frac{\partial h_{\gamma\delta}}{\partial \bar{s}}
= \frac{\partial^2}{\partial s \partial \bar{s}} \log \det(h_{\alpha\bar{\beta}}) + h^{\delta\alpha} \frac{\partial h_{\alpha\bar{\beta}}}{\partial s} h^\delta_{\gamma\delta} \frac{\partial h_{\gamma\delta}}{\partial \bar{s}}
\]
By (5.3), we have
\[
\frac{\partial^2}{\partial s \partial \bar{s}} \log \det(h_{\alpha\bar{\beta}}) = \varepsilon \rho_{\varepsilon} \left( \frac{\partial}{\partial s}, \frac{\partial}{\partial \bar{s}} \right) - \varepsilon \omega \left( \frac{\partial}{\partial s}, \frac{\partial}{\partial \bar{s}} \right) + \Theta_{ss}(E).
\]
Hence it follows that
\[
(5.4) \quad h^\delta\gamma h_{s\bar{s}\gamma\delta} = \varepsilon (h_{s\bar{s}} - g_{s\bar{s}}) + \Theta_{ss}(E) + h_{s\bar{\beta}a} h_{s\gamma\beta} h^{\bar{\beta}a} h_{\gamma\delta}.
\]
Next we consider the term \( h^\delta\gamma \left( h_{s\bar{\beta}}h^{\bar{\beta}a}h_{a\bar{s}} \right)_{\gamma\delta} \), which can be written by
\[
h^\delta\gamma \left( h_{s\bar{\beta}}h^{\bar{\beta}a}h_{a\bar{s}} \right)_{\gamma\delta}.
\]
Define a tensor \( \{ A_{s}^{\alpha}_{\beta} \} \) by
\[
A_{s}^{\alpha}_{\beta} = -h_{s\bar{s}}^{\alpha} \delta_{\beta}.
\]
Then it follows that
\[
\overline{\partial v_{\rho_{\varepsilon}}} = A_{s}^{\alpha}_{\beta} \frac{\partial}{\partial \bar{z}^\alpha} \otimes \overline{dz^\beta}.
\]
Hence we have
\[ h^{\delta\gamma}(h_s^{\sigma \delta} h_{\delta})^{\gamma} = h^{\delta\gamma} \left( h_s^{\sigma \gamma} h_{\delta} + A_s^{\sigma \delta} A_{\delta\gamma} + h_{\delta}^{\sigma \gamma} h_{\delta\gamma} + h_s^{\sigma} A_{\delta\gamma}\delta \right) := I_1 + I_2 + I_3 + I_4. \]

First of all, it is obvious that
\[ I_2 = A_s^{\sigma \delta} A_{\delta\gamma} h^{\delta\gamma} = \left| \partial v_{\rho} \right|^2_{\rho_s}. \]
And the term \( I_3 \) is equal to \( h_{\delta\gamma}^{\delta\gamma} h_{\delta\gamma}^{\delta\gamma} h_{\delta\gamma}^{\delta\gamma} \), which is appeared in (5.4). So these terms are cancelled in the last computation.

Before computing \( I_1 \) and \( I_4 \), we introduce some ingredients. Let \( R_{\alpha \beta \gamma}^\delta \) be a Riemann curvature tensor of \( \rho_{\epsilon}|_{X_y} \). Then by the commutation formula for covariants derivatives, we have
\begin{align*}
(5.5) & \quad T^{\alpha}_{\beta \gamma} - T^{\alpha}_{\gamma \beta} = R^{\alpha}_{\delta \beta \gamma} T^{\delta}. \\
\end{align*}
Let \( R_{\alpha \beta} := R^{\gamma}_{\alpha \beta \gamma} \) be the Ricci tensor of \( \rho_{\epsilon}|_{X_y} \). By the definition of \( h^{\rho_{\epsilon}}_{\gamma} \) in Remark 2.3, we have
\[ \Theta_{h^{\rho_{\epsilon}}_{\gamma}}|_{X_y} = -\text{Ric}(\rho_{\epsilon}|_{X_y}). \]
Hence it follows from (5.3) that
\[ R_{\alpha \beta} = \varepsilon h_{\alpha \beta} - \varepsilon g_{\alpha \beta}. \]

Lemma 5.2. Let \( \bar{\partial}^* \) be the adjoint of \( \bar{\partial} \) with respect to the \( L^2 \)-inner product with \( \rho_{\epsilon}|_{X_y} \), which is defined by
\[ \bar{\partial}^* \left( A_s^{\alpha \beta} \frac{\partial}{\partial z^\alpha} \otimes dz^\beta \right) := h^{\beta\gamma} A_s^{\alpha \beta \gamma} \frac{\partial}{\partial z^\alpha}. \]
Then we have the following:
\begin{align*}
(5.6) & \quad \bar{\partial}^* (\bar{\partial} v_{\rho}) = \varepsilon \left( g_{\delta\beta}^{\delta\alpha} - h_{\delta\beta}^{\delta\alpha} \right) \frac{\partial}{\partial z^\alpha}. \\
\end{align*}
In particular, we have
\[ h^{\beta\gamma} A_s^{\alpha \beta \gamma} = \varepsilon \left( g_{\delta\beta}^{\delta\alpha} - h_{\delta\beta}^{\delta\alpha} \right). \]

Proof. Since the Riemannian connection induced by a Kähler metric is torsion-free, we have
\[ h^{\beta\gamma} A_s^{\alpha \beta \gamma} = -h^{\beta\gamma} h^{\delta\alpha} h_{\delta\beta \gamma} = -h^{\beta\gamma} h^{\delta\alpha} h_{\delta\beta \gamma}. \]
By (5.3) and (5.5), it follows that

\[ h^{\beta\gamma} A_{s}^{\alpha} h_{\beta\gamma} = -h^{\beta\gamma} h^{\delta\alpha} \left( h_{s} h_{\gamma\delta} - h_{s} R_{\beta\delta}^{\gamma} \right) \]

\[ = -h^{\delta\alpha} \left[ \left( h^{\beta\gamma} \frac{\partial h_{\beta\gamma}}{\partial s} \right)_{\gamma\delta} - h_{s} R_{\beta\delta}^{\gamma} \right] \]

\[ = -h^{\delta\alpha} \left[ \left( \frac{\partial}{\partial s} \log \det(h_{\alpha\delta}) \right)_{\beta\delta} + h_{s} R_{\delta}^{\gamma} \right] \]

\[ = -h^{\delta\alpha} \left[ (\Theta_{h^{\mu_{e}}}_{X/Y})_{s} + h_{s} h^{\gamma\lambda} R_{\gamma\delta}^{\lambda} \right] \]

\[ = -\varepsilon h^{\delta\alpha} \left[ h_{s} - g_{s} - h_{s} h^{\gamma\lambda} (h_{\gamma\delta} - g_{\gamma\delta}) \right] \]

\[ = \varepsilon \left( g_{s} h^{\delta\alpha} - h_{s} g^{\delta\alpha} \right) \]

This completes the proof. \( \square \)

Next we compute the term \( I_{1} \):

\[ I_{1} = h_{s} h_{s}^{\sigma} h_{\gamma\delta} h^{\delta\gamma} \]

\[ = h_{s} \left( -A_{s}^{\sigma} h_{\gamma\delta}^{\delta\gamma} + h_{s} \lambda R_{\gamma\delta}^{\sigma} h^{\delta\gamma} \right) \]

\[ = h_{s} \left[ -\varepsilon \left( g_{s} h^{\sigma} - h_{s} g^{\sigma} \right) - h_{s} \lambda R_{\sigma}^{\lambda} \right] \]

\[ = h_{s} \left[ -\varepsilon \left( g_{s} h^{\sigma} - h_{s} g^{\sigma} \right) - h_{s} \lambda R_{\sigma}^{\lambda} \right] \]

\[ = \varepsilon \left( g_{s} h^{\sigma} - h_{s} g^{\sigma} \right) \]

Finally we compute the term \( I_{4} \):

\[ I_{4} = h^{\gamma\delta} h_{s}^{\sigma} A_{s}^{\sigma} \]

\[ = h_{s} \left( -h^{\gamma\delta} A_{s}^{\sigma} \right) \]

\[ = h_{s} \left[ -h^{\gamma\delta} A_{s}^{\sigma} \right] \]

\[ = h_{s} \varepsilon \left( g_{s} h^{\delta\sigma} - h_{s} g^{\delta\sigma} \right) \]

\[ = \varepsilon \left( h_{s} h^{\delta\sigma} - h_{s} h^{\delta\sigma} \right) \].
Together with all computations, it follows that
\[
\Delta_{\rho_{\varepsilon}} c(\rho_{\varepsilon}) = \varepsilon(h_{ss} - g_{ss}) + \Theta_{ss}(E) - \left| \partial v_{\rho_{\varepsilon}} \right|_{\rho_{\varepsilon}}^2 \\
- \varepsilon \left( h_{s\bar{s}} h^{\bar{s}a} h_{a\bar{s}} - g_{s\bar{s}} h^{\bar{s}a} h_{a\bar{s}} \right) \\
- \varepsilon \left( h_{s\bar{s}} h^{\bar{s}a} g_{a\bar{s}} - h_{s\bar{s}} g^{\bar{s}a} h_{a\bar{s}} \right) \\
= \Theta_{ss}(E) - \left| \partial v_{\rho_{\varepsilon}} \right|_{\rho_{\varepsilon}}^2 + \varepsilon \left( h_{ss} - h_{s\bar{s}} h^{\bar{s}a} h_{a\bar{s}} \right) \\
+ \varepsilon \left( h_{s\bar{s}} - g_{s\bar{s}} h^{\bar{s}a} h_{a\bar{s}} - h_{s\bar{s}} h^{\bar{s}a} g_{a\bar{s}} + h_{s\bar{s}} g^{\bar{s}a} h_{a\bar{s}} \right).
\]
Since
\[
\omega(v_{\rho_{\varepsilon}}, \overline{v_{\rho_{\varepsilon}}}) = g_{ss} - g_{s\bar{s}} h^{\bar{s}a} h_{a\bar{s}} - h_{s\bar{s}} h^{\bar{s}a} g_{a\bar{s}} + h_{s\bar{s}} g^{\bar{s}a} h_{a\bar{s}},
\]
it follows that
\[
-\Delta_{\rho_{\varepsilon}} c(\rho_{\varepsilon}) + \varepsilon c(\rho_{\varepsilon}) = \varepsilon \omega(v_{\rho_{\varepsilon}}, \overline{v_{\rho_{\varepsilon}}}) + \left| \partial v_{\rho_{\varepsilon}} \right|_{\rho_{\varepsilon}}^2 - \Theta_{ss}(E).
\]
Therefore, we have the conclusion. \(\square\)

**Corollary 5.3.** Let \(\rho\) be the fiberwise Ricci-flat metric in Theorem 5.1. Then the following PDE holds on each fiber \(X_y\):
\[
-\Delta_{\rho} c(\rho) = \left| \partial v_{\rho} \right|_{\rho}^2 - \Theta_{ss}(E).
\]

**Proof.** Recall that the fiberwise Ricci-flat metric \(\rho\) satisfies the following:
\[
\Theta_{\rho X/Y} (K_{X/Y}) = -dd^c \log \|u\|_{s}^2 = \Theta(E)
\]
If we apply the same computation with the proof of Theorem 5.1 to \(\rho\) using the above equation, then we have the conclusion.

On the other hand, it is also an easy consequence of the convergence of the form \(\rho_{\varepsilon}\) to \(\rho\) as \(\varepsilon \to 0\) by passing through a subsequence for each \(y \in Y\). (More precisely, the function \(\varphi_{\varepsilon}\) converges to \(\varphi\) as \(\varepsilon \to 0\).) This will be proved in the next section. \(\square\)

**Remark 5.4.** The computations in Corollary 5.3 do not use the normalization condition of \(\varphi\). Hence it is easy to see that for any \(d\)-closed smooth real \((1, 1)\)-form \(\tau\) whose restriction on each fiber is the Ricci-flat metric we have
\[
-\Delta_{\tau} c(\tau) = \left| \partial v_{\tau} \right|_{\tau}^2 - \Theta_{ss}(E).
\]

Now we are at the position of proving the positivity of the direct image \(p_{*} \rho^{n+1}_{\varepsilon}\). As we mentioned in Subsection 2.1, it is enough to show that the fiber integral \(\int_{X_s} c(\rho) \rho^n\) is positive. It follows from Theorem 5.1 and Proposition 4.6 that
\[
\int_{X_s/D} c(\rho_{\varepsilon}) \rho^n_{\varepsilon} = \int_{X_s} \frac{1}{\varepsilon} \left[ \Delta_{\rho_{\varepsilon}} c(\rho_{\varepsilon}) + \left| \partial v_{\rho_{\varepsilon}} \right|_{\rho_{\varepsilon}}^2 - \Theta_{ss}(E) + \varepsilon \omega(v_{\rho_{\varepsilon}}, \overline{v_{\rho_{\varepsilon}}}) \right] \rho^n_{\varepsilon} \\
= \frac{1}{\varepsilon} \left[ \left\| \partial v_{\rho_{\varepsilon}} \right\|_{L^2_{\rho_{\varepsilon}}(X_s)}^2 - \Theta_{ss}(E) \right] + \int_{X_s} \omega(v_{\rho_{\varepsilon}}, \overline{v_{\rho_{\varepsilon}}}) \rho^n_{\varepsilon} \\
\geq \int_{X_s} \omega(v_{\rho_{\varepsilon}}, \overline{v_{\rho_{\varepsilon}}}) \rho^n_{\varepsilon}.
\]
We already know that on each fiber $X_s$, the $p_x|_{X_s}$ converges to $\rho|_{X_s}$ by Corollary 3.5. Therefore, Proposition 5.5, which will be proved in the next section, says that
\begin{equation}
\int_{X/D} c(\rho)\rho^n \geq \int_{X_s} \omega(v_p, \bar{\nu}_p)\rho^n.
\end{equation}

In particular, $p_x\rho^{n+1}$ is positive.

**Proposition 5.5.** On each fiber $X_y$, there exists a sequence $\{\varepsilon_j\}_{j \in \mathbb{N}}$ converging to 0 as $j \to \infty$ such that
\[
c(\rho_{\varepsilon_j}) \to c(\rho) \quad \text{and} \quad \bar{\partial}\nu_{\rho_{\varepsilon_j}} \to \bar{\partial}\nu_{\rho} \quad \text{as} \quad j \to \infty.
\]

We end this section with the proof of Theorem 1.2.

**Proof of Theorem 1.2.** It is enough to prove when the family is over the unit disc $D$ in $\mathbb{C}$. Let $s \in D$. Recall that $c(\rho)$ satisfies
\[-\Delta_c(\rho) = |\bar{\partial}\nu_{\rho}|^2 - \Theta_{\varepsilon x}(E).\]
It follows from the Green kernel formula that
\[
c(\rho) = \int_{X_s} c(\rho)\rho^n + \int_{X_s} G_s(z, w) \left(|\bar{\partial}\nu_{\rho}|^2 - \Theta_{\varepsilon x}(E)\right)\rho^n.
\]
Since the integral of $G_s(z, w)$ is zero, it follows that
\[
c(\rho) \geq \int_{X_s} c(\rho)\rho^n - \int_{X_s} G_s(z, w) |\bar{\partial}\nu_{\rho}|^2 \rho^n
= \int_{X_s} c(\rho)\rho^n - K(s) \int_{X_s} |\bar{\partial}\nu_{\rho}|^2 \rho^n.
= \int_{X_s} c(\rho)\rho^n - K(s) \omega^{WP}(v, \bar{v}).
\]
Equation (5.7) implies that
\[
c(\rho) + K(s) \omega^{WP}(v, \bar{v}) \geq \int_{X_s} c(\rho)\rho^n \geq \int_{X_s} \omega(v_p, \bar{\nu}_p)\rho^n > 0.
\]
On the other hand, it is easy to see that
\[
c(\rho + K(s) \omega^{WP}) = c(\rho) + K(s) \omega^{WP}(v, \bar{v}).
\]
This concludes that $\rho + K(s) \omega^{WP}$ is positive on $X$. \hfill \square

**6. Approximation of the Geodesic Curvature**

In this section, we shall prove Proposition 5.5.

First we recall the setting: Let $p : X \to D$ be a Calabi-Yau fibration and let $\omega$ be a fixed Kähler form on $X$. For each fiber $X_y$, we have a unique solution $\varphi_{y, \varepsilon}$ of the following complex Monge-Ampère equation:
\[
(\omega_y + dd^c\varphi_{y, \varepsilon})^n = e^{\varepsilon \varphi_{y, \varepsilon}} e^{n\eta_y}(\omega_y)^n \quad \text{and}
\]
\[
\omega_y + dd^c\varphi_{y, \varepsilon} > 0,
\]
where $\eta$ is defined in Section 4. As we mentioned, we can consider $\varphi_{\varepsilon}$ as a smooth function on $X$ by letting
\[
\varphi_{\varepsilon}(x) := \varphi_{y, \varepsilon}(x),
\]
where $y = p(x)$. Denote by $\rho_{\varepsilon} = \omega + dd^c\varphi_{\varepsilon}$.
On the other hand, for each fiber $X_y$, we have the solution $\varphi_y$ of the following complex Monge-Ampère equation:

\[
(\omega_y + dd^c \varphi_y)^n = e^{\eta y} (\omega_y)^n, \quad \omega_y + dd^c \varphi_y > 0,
\]

which is normalized by

\[
\int_{X_y} \varphi_y e^{\eta y} (\omega_y)^n = 0.
\]

Then $\varphi$ is a smooth function on $X$. We denote by $\rho = \omega + dd^c \varphi$. It is remarkable to note that $\rho_\varepsilon$ and $\rho$ are uniformly equivalent on $X_y$ by Proposition 3.2.

In this section, we write the horizontal lifting $v_\rho$ of $\partial/\partial s$ with respect to $\rho$ as follows:

\[
v_\rho = \frac{\partial}{\partial s} + a_\alpha \frac{\partial}{\partial z^\alpha} = \frac{\partial}{\partial s} - h_{\alpha \beta} h^{\beta \alpha} \frac{\partial}{\partial z^\alpha}.
\]

in an admissible coordinate $(z, s)$ in $X$.

**Theorem 6.1.** For a fixed fiber $X_y$, the following holds:

\[
\varphi_\varepsilon \to \varphi, \quad v_\rho \varphi_\varepsilon \to v_\rho \varphi \quad \text{and} \quad \overline{v_\rho} v_\rho \varphi_\varepsilon \to \overline{v_\rho} v_\rho \varphi
\]

as $\varepsilon \to 0$ in $C^{k, \alpha}(X_y)$-topology for any $k \in \mathbb{N}$ and $\alpha \in (0, 1)$ by passing through a subsequence.

It is obvious that this theorem implies Proposition 5.5.

In the proof, we fix a fiber $X_y$ and omit the subscript $y$, if there is no confusion. Every convergence means the convergence by passing through a subsequence in the topology of $C^{k, \alpha}(X_y)$ for any $k \in \mathbb{N}$ and $\alpha \in (0, 1)$.

It is easy to see that Corollary 3.5 yields the first assertion. This also implies that there exists a uniform constant $C > 0$ such that

\[
\frac{1}{C} \omega_y < \rho_\varepsilon |_{X_y} < C \omega_y,
\]

for $0 < \varepsilon \leq 1$.

Before going to the further proof of Theorem 6.1 we introduce the following proposition about the fiber integral.

**Proposition 6.2.** Let $\tau$ be a $d$-closed real $(1, 1)$-form on $X$ whose restriction on each fiber $X_s$ is positive definite. For a smooth function $f$ on $X$, we have

\[
\frac{\partial}{\partial s} \int_{X_s} f \tau^n = \int_{X_s} L_{v_\rho} (f \tau^n) = \int_{X_s} (v_\tau f) \tau^n.
\]

In particular, if $\int_{X_s} f \tau^n = 0$ for $s \in \mathcal{D}$, then

\[
\int_{X_s} (v_\tau f) \tau^n = 0.
\]
Proof. The first equality is mentioned in Section 3.2. Cartan’s magic formula and Stokes’ theorem imply that
\[ \frac{\partial}{\partial s} \int_{X_s} f \tau^n = \int_{X_s} L_{v^s} (f \tau^n) \]
\[ = \int_{X_s} (d \circ i_{v^s} + i_{v^s} \circ d) (f \tau^n) \]
\[ = \int_{X_s} d (i_{v^s} (f \tau^n)) + \int_{X_s} i_{v^s} (df \wedge \tau^n) \]
\[ = \int_{X_s} (v^s f) \tau^n - \int_{X_s} df \wedge i_{v^s} \tau^n. \]

On the other hand, Lemma 2.3 implies that
\[ i_{v^s} \tau^n = i_{v^s} \tau \wedge \tau^{n-1} = \sqrt{-1} c(\tau) \wedge \tau^{n-1} \wedge d\bar{s}. \]
Hence we have
\[ \int_{X_s} df \wedge i_{v^s} \tau^n = \int_{X_s} \sqrt{-1} c(\tau) df \wedge \tau^{n-1} \wedge d\bar{s} = 0. \]
This completes the proof. \(\square\)

Now we go back to the proof of the second assertion. Taking logarithm of (6.1) and differentiating it with respect to \(v_p\), we have
\[ (h_\varepsilon)^{\beta_a} v^p (g_{\alpha\bar{\beta}} + (\varphi_\varepsilon)_{\alpha\bar{\beta}}) = \varepsilon v^p \varphi_\varepsilon + v^p \eta + g^{\alpha\bar{\beta}} v^p (g_{\alpha\bar{\beta}}). \]
As in Section 3, we have
\[- \Delta_{\rho_\varepsilon} (v^p \varphi_\varepsilon) + \varepsilon (v^p \varphi_\varepsilon) = -v^p \eta + (h_\varepsilon)^{\alpha\bar{\beta}} (v^p (g_{\alpha\bar{\beta}}) + [v^p, \varphi_\varepsilon]_{\alpha\bar{\beta}}) - g^{\alpha\bar{\beta}} v^p (g_{\alpha\bar{\beta}}), \]
where \(\Delta_{\rho_\varepsilon}\) is the Laplace-Beltrami operator of \(\rho_\varepsilon\) and
\[- \Delta_{\rho_\varepsilon} (v^p \varphi_\varepsilon) + \varepsilon (v^p \varphi_\varepsilon) = R_\varepsilon. \]
We denote the right hand side by \(R_\varepsilon\). Hence \(v^p \varphi_\varepsilon\) satisfies the following equation:
\[ - \Delta_{\rho_\varepsilon} (v^p \varphi_\varepsilon) + \varepsilon (v^p \varphi_\varepsilon) = R_\varepsilon. \]
Then Proposition 3.6 implies that there exists a uniform constant \(C > 0\) such that
\[ \|v^p \varphi_\varepsilon\|_{C^k,\alpha(X_s)} < C. \]

By the same computation to (6.2), \(v^p \varphi\) satisfies that
\[ - \Delta_{\rho} (v^p \varphi) = R, \]
where
\[ R = -v^p \eta + h^{\alpha\bar{\beta}} (v^p (g_{\alpha\bar{\beta}}) + [v^p, \varphi]_{\alpha\bar{\beta}}) - g^{\alpha\bar{\beta}} v^p (g_{\alpha\bar{\beta}}). \]
Since \(\varphi_\varepsilon\) converges to \(\varphi\) and \([v^p, \varphi]_{\alpha\bar{\beta}}\) does not include \(s\)-derivative of \(\varphi_\varepsilon\), we have
\[ (h_\varepsilon)^{\beta_a} \to h^{\beta_a} \] and \([v^p, \varphi_\varepsilon]_{\alpha\bar{\beta}} \to [v^p, \varphi]_{\alpha\bar{\beta}}\) as \(\varepsilon \to 0.\)
It follows that Equation (6.5) converges to Equation (6.6) as \(\varepsilon \to 0.\) Since Proposition 6.2 says that \(v^p \varphi\) is the unique solution of (6.6) which satisfies that
\[ \int_{X_s} (v^p \varphi) \rho^n = 0, \]
the following Lemma completes the proof.

Lemma 6.3. The following holds:

\[
\lim_{\varepsilon \to 0} \int X_s (v_\rho \varphi_\varepsilon) \rho^n = 0.
\]

Proof. Integrating (6.1), we have

\[
1 = \int X_s e^{\varepsilon \varphi_\varepsilon + \eta} \omega^n.
\]

Differentiating with respect to \( s \), we have

\[
0 = \frac{\partial}{\partial s} \int X_s e^{\varepsilon \varphi_\varepsilon + \eta} \omega^n = \int X_s v_\rho (e^{\varepsilon \varphi_\varepsilon}) \rho^n = \varepsilon \int X_s (v_\rho \varphi_\varepsilon) e^{\varepsilon \varphi_\varepsilon} \rho^n.
\]

Since \( e^{\varepsilon \varphi_\varepsilon} (\rho_\varepsilon)^n = \rho^n \) on each fiber \( X_s \),

\[
\int X_s (v_\rho \varphi_\varepsilon) (\rho_\varepsilon)^n = 0.
\]

Since \( \rho_\varepsilon \) and \( \rho \) is uniformly equivalent on \( X_s \), this completes the proof. \( \square \)

It remains only to prove the last assertion.

Differentiating (6.5) with respect to \( \overline{v_\rho} \), we have

\[
- \Delta_{\rho_\varepsilon} (\overline{v_\rho v_\rho \varphi_\varepsilon}) + \varepsilon (\overline{v_\rho v_\rho \varphi_\varepsilon}) = \overline{v_\rho} \left( (h^{\varepsilon})^{\beta \omega} \right) \cdot (v_\rho (\varphi_\varepsilon))_{\alpha \beta} + \overline{v_\rho} (R_\varepsilon) + (h^{\varepsilon})^{\beta \omega} [\overline{v_\rho}, v_\rho \varphi_\varepsilon]_{\alpha \beta}.
\]

Then Proposition 3.6 implies that there exists a uniform constant \( C > 0 \) such that

\[\| \overline{v_\rho v_\rho \varphi_\varepsilon} \|_{C^{k,\alpha}(X_s)} < C.\]

By the same way, \( \overline{v_\rho v_\rho \varphi} \) satisfies that

\[
- \Delta_{\rho} \overline{v_\rho v_\rho \varphi} = \overline{v_\rho} \left( h^{\beta \omega} \right) \cdot (v_\rho \varphi)_{\alpha \beta} + \overline{v_\rho} R + h^{\beta \omega} [\overline{v_\rho}, v_\rho \varphi]_{\alpha \beta}.
\]

We already know that \( \varphi_\varepsilon \to \varphi \) and \( v_\rho \varphi_\varepsilon \to v_\rho \varphi \) as \( \varepsilon \to 0 \) on \( X_y \). Hence the similar argument says that the RHS of (6.7) converges to the RHS of (6.8) as \( \varepsilon \to 0 \). Since Proposition 6.2 says that \( \overline{v_\rho v_\rho \varphi} \) is the unique solution of (6.8) which satisfies that

\[
\int X_s (\overline{v_\rho v_\rho \varphi}) \rho^n = 0,
\]

As the previous argument, the following lemma completes the proof.

Lemma 6.4. The following holds:

\[
\lim_{\varepsilon \to 0} \int X_s (\overline{v_\rho v_\rho \varphi_\varepsilon}) \rho^n = 0.
\]

Proof. Integrating (6.1), we have

\[
1 = \int X_s e^{\varepsilon \varphi_\varepsilon + \eta} \omega^n.
\]
Differentiating with respect to $s$ and $\bar{s}$, we have
\[
0 = \frac{\partial^2}{\partial \bar{s} \partial s} \int_{X_s} e^{\varepsilon \varphi + \eta} \omega^n = \int_{X_s} (\overline{\nu}_p \nu_p e^{\varepsilon \varphi}) \rho^n
\]
\[
= \varepsilon \int_{X_s} (\overline{\nu}_p \nu_p \varphi_e) e^{\varepsilon \varphi} \rho^n + \varepsilon^2 \int_{X_s} |\nu_p \varphi_e|^2 e^{\varepsilon \varphi} \rho^n.
\]
Since $\varphi_e$ and $\nu_p \varphi_e$ are uniformly bounded, it follows that
\[
\int_{X_s} (\overline{\nu}_p \nu_p \varphi_e) (\rho_e)^n \to 0 \quad \text{as} \quad \varepsilon \to 0.
\]
This completes the proof as in the proof of Lemma 6.3.

7. Some remarks

As we mentioned in Introduction, our method does not show the positivity or semipositivity of the fiberwise Ricci-flat metrics. But in a special case, we have the positivity. In the next section, we will introduce an example which is in this case.

Corollary 7.1. Suppose that $|\overline{\partial} \nu_p|_\rho$ depends only on $s$-variable (i.e., it is a constant on each fiber.) Then $\rho$ is positive on $X$.

Proof. Since $|\overline{\partial} \nu_p|_\rho$ is constant on each fiber $X_s$, Proposition 4.5 says that $|\overline{\partial} \nu_p|^2 = \Theta_{s\bar{s}}(E)$. It follows that
\[
-\Delta \rho c(\rho) = 0,
\]
i.e., $c(\rho)$ is a constant on each fiber. Hence we have
\[
c(\rho) = \int_{X_s} c(\rho) \rho^n.
\]
Then Theorem 1.1 completes the proof.

Now we consider a different type of fiberwise Ricci-flat metric. Let $p : X \to D$ be a Calabi-Yau fibration and let $\omega$ be a fixed Kähler form on $X$. By the same argument, there exists a unique smooth function $\psi$ in $X$ such that
\[
(\omega_y + dd^c \psi_y)^n = e^{\eta_y} (\omega_y)^n,
\]
\[
\omega_y + dd^c \psi_y > 0
\]
on each fiber $X_y$ with the following normalization condition:
\[
\int_{X_y} \psi_y (\omega_y)^n = 0.
\]
Obviously, $\tilde{\rho} := \omega + dd^c \psi$ gives another fiberwise Ricci-flat metric on $X$. This metric is called semi-flat or semi-Ricci-flat metric on the polarized family of Calabi-Yau manifolds (cf, see [33, 37, 34]). By Remark 5.3 we have the same PDE:
\[
-\Delta c(\tilde{\rho}) = |\overline{\partial} v_p|^2 - \Theta_{s\bar{s}}(E).
\]
By the uniqueness of the solution of complex Monge-Ampère equation, it is easy to see that $\psi = \varphi - A(y)$ where
\[
A(y) = \int_{X_y} \varphi \omega^n.
\]
Then Theorem 1.1 and Theorem 1.2 immediately imply the following.
Corollary 7.2. Under the hypothesis of Theorem 1.1 and Theorem 1.2, we have the following:

1. $p_\ast \hat{\rho}^{n+1} + d\bar{c} A$ is positive on $Y$.
2. $\tilde{\rho} + d\bar{c} A + K(y)\omega_{WP}$ is positive on $X$.

Remark 7.3. It is pointed by Demaiily and Eyssidieux that the fiberwise Ricci-flat metric in Theorem 1.1 and the semi-Ricci-flat metric are not uniquely determined in the cohomology class $[\omega]$. More precisely, even if $\omega_1$ and $\omega_2$ are Kähler metrics in $X$ which are in the same cohomology class $[\omega]$, the fiberwise Ricci-flat metrics constructed in Theorem 1.1 (or semi-Ricci-flat metrics above) are different. Hence it is interesting to ask the canonical way to define the fiberwise Ricci-flat metric on Calabi-Yau fibrations, which is uniquely determined in each Kähler class $[\omega]$ in $X$.

8. An example: a family of elliptic curves

In this section, we compute the fiberwise Ricci-flat metric on the well known example which is the family of elliptic curves. The computation in this section is due to Magnusson. For the details, we refer [25, 26].

Let $\mathbb{H}$ be a upper half plane in $\mathbb{C}$. Let $(z, s)$ be a Euclidean coordinate on $\mathbb{C} \times \mathbb{H}$. Define a group $G$ by

$$G = \{g_{n,m} : g_{n,m}(z, s) = (z + n + ms, s)\}.$$  

Then $G$ acts on $\mathbb{C} \times \mathbb{H}$ properly discontinuously. The quotient space $\mathbb{C} \times \mathbb{H}/G$ forms a universal family of elliptic curves, call it $X$.

The $(1, 1)$-form $\sqrt{-1} \frac{1}{2} dz \wedge d\bar{z}$ on $\mathbb{C}$ descends to a Ricci-flat Kähler form on each $X_s$. Note that

$$\text{Vol}(X_s) = \int_{X_s} \sqrt{-1} \frac{1}{2} dz \wedge d\bar{z} = \text{Im } s.$$  

Since $dz$ is a nonvanishing holomorphic section of the direct image of the relative canonical line bundle, the curvature $\Theta(E)$ is

$$\Theta(E) = -d\bar{c} \log \|dz\|^2 = -d\bar{c} \log \int_{X_s} \sqrt{-1} dz \wedge d\bar{z} = -d\bar{c} \log \text{Im } s = \frac{1}{|s - \bar{s}|^2} \sqrt{-1} ds \wedge d\bar{s}.$$  

There exists a Kähler form $\rho$ on $X$ such that $\pi^{-1}(\rho) = \hat{\rho}$ is written by the following:

$$\hat{\rho} = \sqrt{-1} \left( h_{s\bar{s}} ds \wedge d\bar{s} + h_{z\bar{z}} dz \wedge d\bar{z} + h_{\bar{s}z} ds \wedge d\bar{z} + h_{\bar{z}s} ds \wedge dz \right).$$  

where

$$\begin{pmatrix} h_{s\bar{s}} & h_{s\bar{z}} \\ h_{z\bar{s}} & h_{z\bar{z}} \end{pmatrix} = \begin{pmatrix} \frac{1}{(\text{Im } s)^2} + \frac{1}{(\text{Im } s)} \frac{z - \bar{z}}{s - \bar{s}} \cdot \frac{z - \bar{z}}{s - \bar{s}} \cdot \frac{z - \bar{z}}{s - \bar{s}} \cdot \frac{z - \bar{z}}{s - \bar{s}} \\ -\frac{1}{\text{Im } s} \frac{z - \bar{z}}{s - \bar{s}} \cdot \frac{z - \bar{z}}{s - \bar{s}} \cdot \frac{z - \bar{z}}{s - \bar{s}} \cdot \frac{z - \bar{z}}{s - \bar{s}} \end{pmatrix}.$$

It is easy to see that $g^\ast \hat{\rho} = \hat{\rho}$ for all $g \in G$. Denote by $v = \partial / \partial s$. The horizontal lift of $v_\rho$ with respect to $\rho$ is computed by

$$v_\rho = \frac{\partial}{\partial s} - h_{s\bar{s}} h_{z\bar{z}} \frac{\partial}{\partial z} = \frac{\partial}{\partial s} + \frac{z - \bar{z}}{s - \bar{s}} \frac{\partial}{\partial z}.$$
It follows that
\[
\bar{\partial} v_\rho = -\frac{1}{s - \bar{s}} \frac{\partial}{\partial z} \otimes d\bar{z}.
\]
It is easy to see that this is the harmonic representative of \( K_s \). Hence we have
\[
|\bar{\partial} v_\rho|^2 = \frac{1}{|s - \bar{s}|^2}.
\]
In particular, \(|\bar{\partial} v_\rho|\) is a function which depends only on \( s \)-variable. The geodesic curvature \( c(\rho) \) is computed by
\[
c(\rho) = h_{s\bar{s}} - h_{s\bar{z}}h_{\bar{z}s} - \frac{1}{(\text{Im} s)^2} \left( \frac{z - \bar{z}}{s - \bar{s}} \right)^2 - \frac{1}{(\text{Im} s)^2} \cdot \text{Im} s
\]
\[
= \frac{1}{(\text{Im} s)^2} > 0.
\]
Therefore, the fiberwise Ricci-flat metric \( \rho \) is positive on \( X \). The direct image of \( \rho^2 \) is given as follows:
\[
p_*\rho^2 = \int_{X_s} \rho^2 = \int_{X_s} c(\rho) \rho \wedge \sqrt{-1} ds \wedge d\bar{s} = \frac{1}{(\text{Im} s)^2} \sqrt{-1} ds \wedge d\bar{s}.
\]
