Keywords: Neonatal Hyperbilirubinemia; Breastfeeding

ABSTRACT
Objectives: Prolonged jaundice is a common condition among neonates. It is defined as persisting hyperbilirubinemia after the 14th day following birth for term babies and after the 21st day for premature babies with serum bilirubin level higher than 5mg/dL. Prolonged unconjugated hyperbilirubinemia may be associated with some pathological conditions. We aimed to evaluate the etiological, clinical and laboratory findings of babies with prolonged jaundice.

Methods: This descriptive cross-sectional study included 90 infants with prolonged jaundice in the pediatric outpatient clinic of Ordu University Training and Research Hospital between 1 January 2015 and 1 October 2020. Demographic characteristics, physical examination and laboratory findings of the babies were collected and analyzed to determine the etiology of neonatal hyperbilirubinemia.

Results: In total 90 infants with prolonged jaundice were presented in this study, including 50 male and 40 female neonates. The most common causes of prolonged neonatal jaundice were breastfeeding, Rh or ABO incompatibility, and urinary tract infection 73%, 13% and 8% of neonates, respectively.

Conclusion: Breast milk jaundice is the most common cause of prolonged jaundice in infants. Although there are some explanations for breast milk jaundice, the exact mechanism leading to breast milk jaundice is not clear. Other reasons that may affect the infants later in life should be investigated in a short time.

Introduction
Prolonged jaundice is defined as persisting hyperbilirubinemia after the 14th day following birth for term babies and after the 21st day for premature babies with serum bilirubin level higher than 5mg/dL [1,2]. It can occur in 2-15% of all newborns and up to 40% in breastfed infants [3]. It is essential to determine the etiology of jaundice caused by unconjugated (indirect) or conjugated (direct) hyperbilirubinemia. Prolonged unconjugated hyperbilirubinemia may be associated with some pathological conditions such as breastfeeding, hemolytic diseases (Rh or ABO incompatibility or glucose-6-phosphate dehydrogenase (G6PD) deficiency), congenital hypothyroidism, urinary infection, Crigler-Najjar or Gilbert syndromes [4,5]. However, the etiology of prolonged jaundice in infants mostly remained unidentified and reported in association with breastfeeding in the literature [6,7]. After excluding the known etiologies, the majority of prolonged jaundice is defined as breast milk jaundice [1]. Tests performed to determine the underlying cause and failure to determine the etiology cause anxiety for both families and physicians. Therefore, we aimed to evaluate the etiological, clinical and laboratory findings of babies with prolonged jaundice.
Materials and Methods

Study Design

This descriptive cross-sectional study included 90 infants with prolonged jaundice in the pediatric outpatient clinic of Ordu University Training and Research Hospital between 1 January 2015 and 1 October 2020. Serum bilirubin level higher than 5mg/dl after the 14th day following birth for term babies and after the 21st day for premature babies was defined as prolonged jaundice [1]. The exclusion criteria were the following: Gestational age <35 weeks, acute-life threatening event, need for neonatal intensive care unit, chromosomal or congenital anomalies, direct bilirubin level >20% of total bilirubin or >2 mg/dL. Prenatal, natal, and postnatal characteristics of the infants were investigated. In prenatal history, preeclampsia, eclampsia, hypertension, and hypothyroidism were evaluated in the mother. Date of birth, birth-weight, gestational age, gender, type of delivery, premature rupture of membranes, and history of birth with meconium were recorded in natal history. Parental consanguinity, sibling numbers, and jaundice history in previous siblings were asked. The time of onset of jaundice, history of previous phototherapy, presence of cephalohematoma in the physical exam, hospitalization history, and feeding status were recorded in postnatal history. Problems encountered during clinical follow-up and treatments applied were determined.

Laboratory evaluations were included the mother-baby blood group, direct Coombs test, reticulocyte count, total bilirubin level at the time of diagnosis with prolonged jaundice, complete blood count, reducing substance in urine, G6PD enzyme level, and Thyroid Function Tests (TSH, fT4). Among the biochemical parameters, serum Aspartate Aminotransferase (AST), Alanine Aminotransferase (ALT), and Gamma-Glutamyl Transferase (GGT) levels were evaluated. After microscopic evaluation, urine culture results were obtained with bladder catheter for those with suspected infection in the bag urine culture. In cases where leukocytes were seen in five or more in each area on microscopic examination of urine, and the growth of ≥ 10,000 CFU/mL microorganisms in urine culture was accepted as UTI, and appropriate antibiotic therapy was administered. In patients with positive urine culture and reducing substance in urine, urine sugar chromatography was performed. Abdominal Ultrasonography (USG) was performed to evaluate the liver and bile ducts.

Data Analysis

Statistical analysis was performed using IBM SPSS 21.0. Shapiro-Wilk test was used to assess if the variables were normally distributed. The results of descriptive statistics were presented for the normally distributed variables as mean ± SD (Standard Deviation) and for non-normally distributed variables as median. Chi-square test was used for categorical data in the comparison between groups. p < 0.05 was considered as statistically significant.

Results

The demographic characteristics of 90 infants with prolonged jaundice were presented in Table 1. In antenatal history, five mothers (5.5%) had hypertension, two (2.2%) had preeclampsia, seven (7.7%) had gestational diabetes, and six (6.6%) had urinary tract infection. Anti-D immunoglobulin (Rhogam®) was administered to two mothers after giving birth. Term, early term, and late preterm infants made up 40%, 50%, and 10% of the infants, respectively, and all infants were appropriate gestational age. There was no difference between these infants except their birth weights and gestational ages (p>0.05). One infant had cephalohematoma. There was no infant taking phenobarbital. Ten infants’ (9%) urine were tested for reducing substances, and one had a positive result. Urine from the infant with a positive result was examined for urine sugar by chromatography, and the result was normal. Serum vitamin B12 levels were examined in 20 infants with a lack of head-lifting, neurological symptoms such as poor smiling and eye-tracking, and maternal vitamin B12 deficiency.

Table 1: Demographic characteristics of infants with prolonged jaundice.

| Characteristic | Result |
|---------------|--------|
| Birth weight (g) (mean± SD) | 3100±480 (2400-4050) |
| Gestational age (weeks) | 38±1.6 (35-41) |
| Term, n (%) | 36 (40%) |
| Early term, n (%) | 45 (50%) |
| Late preterm, n (%) | 9 (10%) |
| Gender, n (%) | 40 (44.44%) |
| Girl | 50 (55.55%) |
| Boy | 42 (46.66%) |
| Route of delivery, n (%) | 48 (53.33%) |
| Vaginal | 77 (85.55%) |
| Cesarean | 10 (11.11%) |
| Feeding mode, n (%) | 3 (3.33%) |
| Breastfeed | 77 (85.55%) |
| Breastfeed+Formula | 10 (11.11%) |
| Formula | 19 (14.58) |
| Age at diagnosis (days) (median) | 38 (42.22%) |
| Sibling, n (%) | 52 (57.77%) |
| Present | 28 (31.11%) |
| Absent | 62 (68.88%) |

| Yes | 10 (11.11%) |
| No | 46 (51.11%) |
| History of Phototherapy for Jaundice | 77 (85.55%) |
| Yes | 28 (31.11%) |
| No | 62 (68.88%) |

Eighteen infants out of 20 had low vitamin B12 levels. Rh and ABO incompatibility between mother and baby was 3.33% (n: 3) and 10% (n: 9), respectively. Subgroup incompatibility could not be...
evaluated. Three infants with Rh incompatibility who had a positive direct Coombs test were received phototherapy, but exchange transfusion was not done. The results of five babies screened for TORCH were negative. None of the 50 cases evaluated by abdominal USG had pathology in the liver or bile ducts. Five patients had unilateral minimal pelvicaliectasis, one had hydrenephrosis, and one had adrenal hemorrhage. None of our cases needed repeat phototherapy. The etiologic distribution of infants with prolonged jaundice was shown in Table 2. Laboratory results of infants were given in Table 3. The etiologic distribution of prolonged jaundice in infants with and without phototherapy history was shown in Table 4. The history of phototherapy was significantly higher in infants diagnosed with isoimmunization (Rh or ABO Incompatibility) (p<0.001).

Table 2: Etiologic distribution of infants with prolonged jaundice.

| Isoimmunization (Rh or ABO Incompatibility) | 12 (13.33%) |
|-------------------------------------------|------------|
| Congenital Hypothyroidy                    | 1 (1.11%) |
| Glucose-6-Phosphate Dehydrogenase Deficiency | 1 (1.11%) |
| Hereditary Spherocytosis                    | 1 (1.11%) |
| Urinary Tract Infection                    | 8 (8.88%) |
| Cephalohematoma                            | 1 (1.1%)  |
| Adrenal Hemorrhage                         | 1 (1.1%)  |
| No etiologic factor determined (breastfeeding) | 66 (73.33%) |

Discussion

Under the results of this study, the most common causes of prolonged neonatal jaundice are breastfeeding, Rh or ABO incompatibility, and UTI, which is compatible with the findings of previous studies conducted in this regard [3,8]. According to many studies in the literature, since no specific etiologies could be confirmed in most infants diagnosed with prolonged unconjugated hyperbilirubinemia, breast milk jaundice is the main cause of prolonged jaundice. In the present study, the etiologic factor was breast milk jaundice in 73.3% of infants with prolonged jaundice [3,8-10]. Beta-glucuronidase, Pregnan-3a, 20b-diol, free fatty acids, and genetic causes (UGT1A1) were blamed for breast milk jaundice [11]. Due to maternal vitamin B12 deficiency, lack of head-lifting, and neurologic symptoms such as poor smiling and eye-tracking, serum vitamin B12 levels were examined in cases with prolonged jaundice of unidentified etiology. 18 infants out of 20 had low vitamin B12 levels. There is no study in the literature showing whether there is an association between prolonged jaundice and vitamin B12 deficiency.

Vitamin B12 is a crucial factor for DNA synthesis, acting as a cofactor for key enzymatic reactions. The deficiency of Vitamin B12 leads to megaloblastic anemia due to ineffective erythropoiesis. It is suggested that ineffective erythropoiesis may cause immature erythrocyte formation that is lysed within the bone marrow. It results in releases of excess quantities of biliverdin, which is ultimately converted to indirect bilirubin leading to unconjugated hyperbilirubinemia. In our study, we could not make further comments, since the number of cases whose serum vitamin B12 levels were checked was very low and there was no control group. Extensive prospective studies are needed to confirm this.

It should be reminded to the family that although breastfeeding is the most common cause of prolonged jaundice, breastfeeding should not be interrupted. In our study, Urinary Tract Infection (UTI) was detected in 8.8% of infants with prolonged jaundice. UTI increases bilirubin load by causing hemolysis in erythrocytes, and causes hyperbilirubinemia by decreasing conjugation in the liver, and decreasing excretion of bilirubin [11]. In some studies, the prevalence of UTI in prolonged jaundice was as low as 5-10%, while it was found to be higher as 15-36% in other studies [1,8,12-17]. Different incidence of UTI may be related to urine culture techniques. In some studies, false positive results may have been found because...
the diagnosis was made only by bag urine culture. Although the prevalence of UTI was different in the literature, prolonged jaundice may be the only finding in infants with UTI. Thus, the microscopic examination and culture of urine should be requested in these infants. For asymptomatic infants with prolonged jaundice whose bag urine culture was positive, confirmation with urine culture obtained by suprapubic aspiration or bladder catheter is recommended [18]. Early diagnosis and treatment of these infants will reduce the risk of urinary tract infections and its complications in the long-term. In the literature, the prevalence of hemolysis due to blood group incompatibilities with a positive Coombs test was found to be 5-13% in the etiology of prolonged jaundice.

Likely, in our study, it was % 13.33 (n: 12) [8,19]. Persistent hemolysis in blood incompatibilities, which is a major risk factor for jaundice, can be explained as the reason for this. In our study, 48.88% (n: 44) of cases with prolonged jaundice were previously received phototherapy. The history of phototherapy was significantly higher in infants diagnosed with isoimmunization (Rh or ABO Incompatibility). The cause of prolonged jaundice can be explained by bilirubin generated by persistent hemolysis. The prevalence of G6PD enzyme deficiency was reported as 6-13% in studies conducted in Turkey [19-21]. It was 1.1% (n: 1) in our study. This can be explained by regional differences. The prevalence of congenital hypothyroidism in infants with prolonged jaundice was reported as 6-8% in the literature [8,9]. It was found to be 1.1% (n: 1) in our study. This difference can be explained by monitoring maternal thyroid diseases during pregnancy, also checking and monitoring newborns’ TSH levels during newborn screening programs.

Conclusion

Breast milk jaundice is the most common cause of prolonged jaundice in infants. Although there are some explanations for breast milk jaundice, the exact mechanism leading to breast milk jaundice is not clear. Other reasons that may affect the infants later in life should be investigated in a short time.

Conflict of Interests

It is not declared by the authors.

Ethical Approval

Ordu University Ethics Committee on 20 August 2020 approved the study.

Funding

The authors received no financial support for the research and/or authorship of this article.

Informed Consent

Written informed consent was not obtained as the study is retrospective. But the Local Ethics Committee approved the current study (20.08.2020/2020-162).
