**Neoansamycins from *Streptomyces* sp. LZ35†**

Mengyujie Liu,a Chunhua Lu,a Ruocong Tang,b Shanren Li,a Haoxin Wangb and Yuemao Shen a,b,c

Previously, activation of the cryptic nam gene cluster led to three new naphthalenic ansamycins with unprecedented n-pentyl and n-butyl side chains from the mutant *Streptomyces* sp. SR201nam1OE strain. In this study, we further characterized the products of the mutant strain and six new neoansamycin congeners, namely neoansamycins D–I (1–6), were elucidated. Among them, compounds 1–3 feature the conserved skeleton of neoansamycins B and C but with n-hexyl side chains, and 4–6 are modified neoansamycins with n-pentyl side chains, illustrating the biosynthetic plasticity and diverse post-PKS modifications of neoansamycins.

**Introduction**

Ansamycins are a family of macrolactam antibiotics with remarkable potential for druggability, including the RNA polymerase inhibitor rifamycin,1 the Hsp90 inhibitor geldanamycin,2 and the potent microtubule inhibitors maytansinoids.3 Over the past ten years, we have focused on discovering ansamycin-producing strains, and obtained twenty-six 3-amino-5-hydroxy benzoic acid (AHBA) synthase gene-positive strains from plant-associated and marine-derived actinomycetes through PCR screening of AHBA synthase genes.4 From these AHBA synthase gene-positive strains, we isolated dozens of ansamycins, including hygrocins,5–7 divergolides,8,9 juanlimycins,9 anansatrienes,10,11 and streptоварcin derivatives ansavarmins A–C.12,13

Recently, *Streptomyces* sp. LZ35 was activated to produce novel naphthalenic ansamycins (neoansamycins A–C) by constitutive overexpression of a LuxR family transcriptional regulatory gene,14 and further ten new benzenic ansamycins (5,10-seco-neoansamycins A–J) were obtained by disrupting the nam7 gene in the SR201nam1OE strain.15 The intriguing structure diversity of the neoansamycins A–C and 5,10-seco-neoansamycins A–J encouraged us to search for more new congeners of neoansamycins. In this study, six new analogues of neoansamycins, namely neoansamycins D–I (1–6), were isolated from the fermentation products of the strain *S*. sp. SR201nam1OE. Their structures were elucidated on the basis of 1D-, 2D-NMR, HRESIMS analysis and X-ray single crystal diffraction. Further, the cytotoxicity and antibacterial activities of compounds 1–6 were also evaluated in this study.

**Results and discussion**

The strain *S*. sp. SR201nam1OE was cultured on ISP3 agar media for 14 days at 28 °C. The 100 L fermented agar was diced and extracted three times with EtOAc/MeOH (80 : 20, v/v) at room temperature. The crude extract was partitioned between ddH2O and EtOAc. The EtOAc extract was further partitioned between petroleum ether (PE) and 95% aqueous MeOH. The MeOH extract (40 g) was subjected to column chromatography over Sephadex LH-20, reversed-phase (RP) C18 silica gel and finally semi-preparative HPLC to yield compounds 1–6 (Fig. 1).

The molecular formula of neoansamycin D (1) was assigned as C_{31}H_{41}NO_{7} on the basis of high resolution ESI MS data (m/z 522.2848 for [M + H]^+ ) (ESI Fig. S1†). Interpretation of the NMR data (Tables 1 and 2) revealed that 1 had similar structure as that of neoansamycin B,16 except for the substitute of a hexyl at C-20 instead of an amyl side chain, and which was further confirmed by the ^1H–^1H COSY and HMBC correlations (ESI Table S1 and Fig. S1†). The NOESY correlations (ESI Table S1†) from H-19 to H-18a and H-20a revealed the relative configurations of 1. Finally, the absolute configurations of neoansamycin D were fully confirmed by the X-ray diffraction analysis (CCDC 1481243†) (Fig. 2).

The high-resolution of neoansamycin E (2) gave a quasi-molecular ion at m/z 540.2952 [M + H]^+ (ESI Fig. B19†) consistent with the molecular formula C_{31}H_{42}NO_{7}. After careful comparison the NMR data of 1 and 2, we found compound 2 is as an analogue of 1. The chemical shifts of C-11 (δ_C 150.3 s) and C-12 (δ_C 118.7 s) in 1 moved to downfield of C-11 (δ_C 209.5 s) and upfield of C-12 (δ_C 2.19; δ_C 49.6 d) in 2, which suggest a keto-enol tautomerization of C-11 and C-12 in 1 and 2 incurred by the ketalization between C-4 hydroxyl and C-12 keto group. The
molecular weight of 2 was more 18 D than that of 1, which further demonstrated the hydrolytic cleavage of the ether bond between C-4 and C-11 in 2. The relative configurations of 2 at C-12, C-16 and C-20 were assigned to be identical to that of 5,10-seco-neoansamycin H\textsuperscript{4} on the basis of the same biosynthetic origin. Likewise, the relative configurations of 2 at C-18 and C-19 were assigned identical to those of neoansamycin D (1) and B\textsuperscript{15} on the basis of the same biosynthetic origin.

Neoansamycin F (3) with a quasi-molecular ion at m/z of 554.2748 [M + H]\textsuperscript{+} was determined to have the molecular formula C\textsubscript{30}H\textsubscript{37}NO\textsubscript{7}. The \textsuperscript{1}H and \textsuperscript{13}C NMR spectra revealed 31 signals, corresponding to four CH\textsubscript{3}, nine CH\textsubscript{2}, six CH and twelve quaternary C-atoms. The HSQC, \textsuperscript{1}H--\textsuperscript{1}H COSY and HMBC experiments revealed that the structure of 3 was similar to that of 1. After careful comparison, we found apparent differences including the chemical shifts at C-3 ([\(\delta_{c} = 91.2\) t] in 3 and [\(\delta_{h} = 2.46\) d, 2.72 d, \(\delta_{c} = 49.9\) t] in 1), which demonstrated the location of hydroxyl at C-3 instead of methine in 1. The NOESY correlations (ESI Table S3\textsuperscript{+}) from H-18a to H-19 and H-20a revealed the relative configurations at C-18, C-19 and C-20 of compound 3. Considering the identical biosynthetic origin, rest of the configurations of 3 were suggested to be identical to those of neoansamycin D (1).

Neoansamycin G (4) was determined to have molecular formula C\textsubscript{17}H\textsubscript{16}NO\textsubscript{12}, on the basis of HRESIMS (m/z 698.3172 [M + H]\textsuperscript{+}) (ESI Fig. S3\textsuperscript{3+}). The \textsuperscript{1}H and \textsuperscript{13}C NMR data with the aid of HSQC, \textsuperscript{1}H--\textsuperscript{1}H COSY and HMBC experiments revealed that 4 was partially identical to neoansamycin B.\textsuperscript{15} The presence of a \(\beta\)-glucuronic acid moiety was revealed by the \textsuperscript{1}H NMR signals at \(\delta_{h} = 5.42\) (d, \(J = 7.6\) Hz), 3.63 (m), 3.55 (m), 3.67 (m) and 4.18 (d, \(J = 9.6\) Hz) (Table 1), and the \textsuperscript{13}C NMR signals at \(\delta_{c} = 101.0\) d, 74.3 d, 77.8 d, 72.7 d, 76.9 d and 170.7 s (Table 2). These assignments were further confirmed by \textsuperscript{1}H--\textsuperscript{1}H COSY and HMBC correlations. The HMBC correlation from H-6\textsuperscript{a} (\(\delta = 3.77, s, 3H\)) to C-6\textsuperscript{-} revealed the presence of 6-O-methyl \(\beta\)-glucuronic acid, which was located at C-9 based on the HMBC correlation from the anomic proton H-1\textsuperscript{t} to C-9. Thus, the structure of 4 was established to be neoansamycin B-9-O-\(\beta\)-glucuronic 6\textsuperscript{-}methyl ester. The relative configurations of 4 were determined identical to those of 1 on the basis of the same biosynthetic origin.

Neoansamycin H (5) was determined as an analogue of 1 with the molecular formula C\textsubscript{30}H\textsubscript{39}NO\textsubscript{7} (HRESIMS m/z 524.2642 [M + H]\textsuperscript{+}) (ESI Fig. S3\textsuperscript{9+}). The 1D, 2D NMR data (ESI Table S5 and Fig. S5\textsuperscript{+}) revealed that 5 was similarly identical to neoansamycin B.\textsuperscript{15} The chemical shifts of C-11 (\(\delta_{c} = 203.8\) s) and C-12 (\(\delta_{c} = 85.8\) s) in 5 and C-11 (\(\delta_{c} = 148.6\) s) and C-12 (\(\delta_{c} = 116.0\) s) in neoansamycin B suggested thetautomerization of enol-form and keto-form at C-11 and C-12 in neoansamycin B and 5, and the downfield shift of C-12 in 5 demonstrated the oxygenation of C-12 and the formation position of the ether bond in 5 is C-4-O-C-12 instead of C-4-O-C-11. The NOESY correlations (ESI Table S5\textsuperscript{+}) from H-12a to H-18a, H-18a to H-19, and H-20a to H-19 revealed the relative configurations of compound 5 at C-12, C-18, C-19 and C-20. The relative configuration of 5 at C-16 was assigned to be identical to that of 5,10-seco-neoansamycin H\textsuperscript{4} on the basis of the same biosynthetic origin.

The molecular formula of neoansamycin I (6) was determined to be C\textsubscript{30}H\textsubscript{41}NO\textsubscript{13} on the basis of HRESIMS (m/z 526.2798 [M + H]\textsuperscript{+}). The planar structure was deduced by analysis of its HMOC, \textsuperscript{1}H--\textsuperscript{1}H COSY and HMBC correlations (ESI Table S6 and Fig. S6\textsuperscript{+}). The presence of dihydropaphthoquinone ring and the formation of a five membered ring (C-2/3/17/18/19) were confirmed by the changes of chemical shifts of C-3 (\(\delta_{c} = 70.2\) d; \(\delta_{h} = 3.11\) s), C-4 (\(\delta_{c} = 195.1\) s), C-17 (\(\delta_{c} = 88.8\) s) and C-18 (\(\delta_{c} = 40.6\) d; \(\delta_{h} = 2.16\) m) in 6 and C-3 (\(\delta_{c} = 48.6\) t; \(\delta_{h} = 2.31\) d & 2.72-2.69 m), C-4 (\(\delta_{c} = 88.6\) s), C-17 (\(\delta_{c} = 213.5\) s) and C-18 (\(\delta_{c} = 59.9\) s) in neoansamycin B.\textsuperscript{15} The keto-form of C-11 was deduced on the basis of the chemical shift of C-11 (\(\delta_{c} = 207.9\) s) in 6. The relative configurations of 6 were assigned to be identical to those of neoansamycin D (1) on the basis of the same biosynthetic origin.

The antimicrobial activities of 1-6 were measured against Bacillus subtilis 86315, Staphylococcus aureus ATCC 25923, Mycobacterium smegmatis mc\textsuperscript{2} 153, and Candida albicans 5314 by the paper disc diffusion assay (20 µg per disc). Only compounds 1, 5 and 6 exhibited modest activity against B. subtilis 86315 (diameters of inhibitory zones 13, 11, and 9 mm, respectively). In addition, 2 exhibited weak activity against Staphylococcus aureus ATCC.
25923 with inhibitory zone of 10 mm. These activities are similar to those of neoansamycins A–C. The highly diversified structures mostly resulted from diverse post-PKS modifications. In particular, post-PKS modifications are critical in determining their bioactivities. 

**Experimental**

**General experimental procedures**

Optical rotations were carried out using an Anton Paar MCP200 automatic polarimeter. The UV spectra were obtained on a TU-1810 spectrophotometer (Beijing Purkinje General Instrument Co., LTD). NMR spectra were recorded on Bruker DRX-600 NMR spectrometer (Bruker Daltonics Inc., Billerica, MA, USA) with tetramethylsilane (TMS) as an internal standard. HRESIMS were carried out on an LTQ-Orbitrap XL. Sephadex LH-20 was obtained from GE Amersham Biosciences (25–100 μm; Piscataway, New Jersey, USA).
Table 2 $^{13}$C NMR spectroscopic data for compounds 1–6 (recorded at 150 MHz, compounds 1, 2, 4, 5 in CD$_2$OD and 3, 6 in DMSO-d$_6$)

| Pos. | 1     | 2     | 3     | 4     | 5     | 6     |

New Jersey) and LiChroprep RP-18 were used for column chromatography (CC) from Merck (40–63 μm; Darmstadt, Germany). Semi-preparative HPLC were performed on an Agilent 1200 equipped with a ZORBAX Eclipse XDB$_{18}$ 5 μm column (9.4 × 250 mm).

**Fermentation and extraction**

The mutant strain SR201nam1OE was cultured on ISP3 medium (oatmeal 30 g, saline salt 1 mL, agar 20 g, pH 7.2) for 14 days at 28 °C. The culture (a total volume of 100 liters) was chopped, diced and extracted three times overnight with an equal volume of EtOAc/MeOH 80 : 20 (v/v) at room temperature and partitioned between ddH$_2$O and EtOAc until the EtOAc layer was colorless. Then, the EtOAc extract was dried with Na$_2$SO$_4$, and the solvent was removed under vacuum at 38 °C. The EtOAc extract was partitioned with petroleum ether (PE) and MeOH until the PE layer was colorless. The MeOH solution was concentrated under vacuum at 38 °C to obtain MeOH extract (40 g).

**Isolation and purification of compounds 1–7**

The MeOH extract (40 g) was subjected to column chromatography over Sephadex LH-20 (120 g) eluted with MeOH to obtain 5 fractions (Fr. 1–5). Fr. 3 (11 g) was chromatographed over Sephadex LH-20 (120 g) eluted with MeOH to obtain 3 fractions, Fr. 3a–3c. Fr. 3b (6.7 g) was subjected to MPLC over RP-18 silica gel (80 g), and 20 subfractions with 200 mL for each gradient were obtained from the elution with 30, 50, 60, 70, 75, 80 and 100% MeOH, respectively. In accordance with TLC results, 4 fractions, Fr. 3b1–3b4 were obtained. Fr. 3b2 (3.1 g) was subjected to CC over Sephadex LH-20 (120 g) eluted with MeOH to obtain 4 fractions, Fr. 3b2a–3b2d. Fr. 3b2c (984 mg) was further subjected to MPLC over RP-18 silica gel (80 g) eluted with 30%, 40%, 50%, 55%, 60% and 100% CH$_3$CN to obtain Fr. 3b2c1–3b2c4. Fr. 3b2c2 (105.2 mg) were purified by semi-preparative HPLC (eluted with 50% acetonitrile, 4 mL min$^{-1}$, UV 320 nm) to yield 4 (3 mg). Fr. 3b2c3 (213 mg) were purified by semi-preparative HPLC (eluted with 55% acetonitrile in 0.05% formic acid, 4 mL min$^{-1}$, UV 320 nm) to yield 3 (1.7 mg), and 6 (1.2 mg).
Fr. 3b3 (2.93 g) was subjected to CC over Sephadex LH-20 (120 g) eluted with MeOH to obtain 3 fractions, Fr. 3b3a–3b3c. Fr. 3b3b (1.03 g) was further subjected to MPLC over RP-18 silica gel (80 g) eluted with 30%, 40%, 50%, 55%, 60%, 70%, and 100% CH3CN to obtain Fr. 3b3b1–3b3b4. Fr. 3b3b3 (153 mg) were purified by semi-preparative HPLC (eluted with 65% acetonitrile in 0.05% formic acid, 4 mL min⁻¹, UV 320 nm) to yield 7 (6.0 mg), 1 (3.0 mg), 2 (2.3 mg) and 5 (8.2 mg).

**Compound 1.** Yellow light crystal: [α]D⁰₂⁰ = −15.80 (c 0.100, MeOH); UV (MeOH) λ max (log e) 306 (2.23), 277 (2.55) nm; 1H and 13C NMR data, see Tables 1 and 2; HRESIMS: m/z 522.2848 [M + H]+ (calcd for C₃₀H₄₀NO₇ + 522.2850).

**Compound 2.** Yellow powder; [α]D⁰₂⁰ = −20.52 (c 0.077, MeOH); UV (MeOH) λ max (log e) 303 (2.28), 277 (2.58) nm; 1H and 13C NMR data, see Tables 1 and 2; HRESIMS: m/z 540.2952 [M + H]+ (calcd for C₃₁H₄₁NO₇ + 540.2956).

**Compound 3.** Yellow light powder; [α]D⁰₂⁰ = −32.10 (c 0.057, MeOH); UV (MeOH) λ max (log e) 306 (2.25), 277 (2.58) nm; 1H and 13C NMR data, see Tables 1 and 2; HRESIMS: m/z 554.2748 [M + H]+ (calcd for C₃₂H₄₂NO₇ + 554.2748).

**Compound 4.** Yellow powder; [α]D⁰₂⁰ = −24.70 (c 0.100, MeOH); UV (MeOH) λ max (log e) 311 (2.16), 280 (2.50) nm; 1H and 13C NMR data, see Tables 1 and 2; HRESIMS: m/z 698.3172 [M + H]+ (calcd for C₃₄H₄₅NO₇ + 698.3170).

**Compound 5.** Red powder; [α]D⁰₂⁰ = −84.22 (c 0.270, MeOH); UV (MeOH) λ max (log e) 304 (2.07), 298 (3.85) nm; 1H and 13C NMR data, see Tables 1 and 2; HRESIMS: m/z 524.2642 [M + H]+ (calcd for C₃₀H₄₄NO₆ + 524.2643).

**Compound 6.** Yellow light powder; [α]D⁰₂⁰ = −46.25 (c 0.040, MeOH); UV (MeOH) λ max (log e) 302 (2.10), 270 (2.43) nm; 1H and 13C NMR data, see Tables 1 and 2; HRESIMS: m/z 526.2798 [M + H]+ (calcd for C₃₀H₄₆NO₆ + 526.2799).

**X-ray crystallographic analysis**

The single-crystal X-ray diffraction intensity data of 1 were collected with a Bruker SMART-1000 diffractometer using graphite-monochromated Mo Kα radiation (λ = 0.71073 Å) by the ω-scan technique [scan width 0–180°, 2θ ≤ 50°] at 293 (2) K. Crystal data of neoansamycin D (1): C₃₁H₄₃NO₆, Mᵣ = 521.67, orthorhombic, a = 8.5601 (9) Å, b = 14.9864 (13) Å, c = 23.2722 (18) Å, α = 90°, β = 90°, γ = 90°, V = 2985.5 (8) Å³, space group P2₁2₁2₁ (1) 2 (1) 2 (1), Z = 4, Dx = 1.232 mg m⁻³, μ (Mo Kα) = 0.698 mm⁻¹, and F(000) = 1192. Crystal dimensions: 0.32 × 0.28 × 0.27 mm³. Independent reflections: 4528 (R int = 0.0495). Theta range for data collection: 3.51 to 66.19°. The final R₁ = 0.0778, wR₂ = 0.1356 (I > 2σ(I)). CCDC number: 1481243.

**Antimicrobial assay**

The antimicrobial activities of compounds 1–6 against *Candida albicans* 5314, *Staphylococcus aureus* ATCC 25923, *Mycobacterium smegmatis* mc² 155, *Pseudomonas aeruginosa* PA01, *Bacillus subtilis* 86315 or *Salmonella enterica* serovar Typhimurium UK-1 χ8956 were measured with a paper disc diffusion assay. Kanamycin and amphotericin were used as positive control.

**Conclusions**

In summary, we isolated and characterized six neoansamycin congeners, namely neoansamycins D–I (1–6), with unusual extender units and diverse post-PKS modifications from the *Streptomyces* sp. SR201nam1OE strain. In particular, although various unusual extender units have been found in other polyketide-derived structures, this study is the first example that n-hexylmalonyl-CoA was used in the biosynthesis of ansamycins. The promptness of neoansamycin PKS could facilitate the bioengineering of novel ansamycins.
