Abstract

Using data accumulated with the CLEO detector corresponding to an integrated luminosity of $L = 5.46 \text{ pb}^{-1}$ on the peak of the $\psi(2S)$ and 20.46 pb$^{-1}$ at $\sqrt{s} = 3.67 \text{ GeV}$, we report preliminary branching fraction measurements for seven new decay modes of the $\psi(2S)$ ($\eta 3\pi, \eta' 3\pi, 2(K^+ K^-)$, $p\bar{p}K^+K^-$, $\Lambda \Lambda \pi^+\pi^-$, $\Lambda \bar{p}K^+$, and $\Lambda \bar{p}K^+\pi^+\pi^-$) and more precise measurements of nine previously measured modes ($2(\pi^+\pi^-), 2(\pi^+\pi^-)\pi^0, \omega \pi^+\pi^-, K^+K^-\pi^+\pi^-, K^+K^-\pi^+\pi^-, K^+K^-K^+K^-, K^+K^-K^+K^-$, $p\bar{p}\pi^+\pi^-$, and $\Lambda \Lambda$). We also include a study of $\omega p\bar{p}$ and obtain an improved upper limit for $\phi p\bar{p}$. Results are compared, where possible, with the corresponding $J/\psi$ branching ratios to test the 12% rule.
In perturbative QCD the states $J/\psi$ and $\psi(2S)$ are non-relativistic bound states of a charm and an anti-charm quark. The decays of these states are expected to be dominated by the annihilation of the constituent $c\bar{c}$ into three gluons. The partial width for the decays into an exclusive hadronic state, $h$, is expected to be proportional to the square of the $c\bar{c}$ wave function overlap at the origin, which is well determined from the leptonic width $\Gamma_h$. Since the strong coupling constant, $\alpha_s$, is not very different at the $J/\psi$ and $\psi(2S)$ masses, it is expected that for any state $h$ the $J/\psi$ and $\psi(2S)$ branching ratios are related by 

$$Q_h = \frac{B(\psi(2S) \rightarrow h)}{B(J/\psi \rightarrow h)} \approx \frac{B(\psi(2S) \rightarrow \ell^+\ell^-)}{B(J/\psi \rightarrow \ell^+\ell^-)} = (12.7 \pm 0.5)\%,$$

where $B$ denotes a branching fraction, $h$ is a particular hadronic final state, and the leptonic branching fractions are taken from the PDG [1]. This relation is sometimes called “the 12% rule”. Modest deviations from the rule are expected [3]. Although the rule works well for some specific decay modes of the $\psi(2S)$, it fails spectacularly for $\psi(2S)$ decays to final states consisting of one vector and one pseudoscalar meson, such as $\rho \pi$.

Values of $Q_h$ have been measured for a wide variety of final states [1, 2, 3]. Most recently CLEO has measured additional 1$^-$ states at the $\psi(2S)$ and the continuum [4], including the first observation of $\psi(2S)$ → $\rho \pi$. A recent review [3] of relevant theory and experiment concludes that current theoretical explanations are unsatisfactory. Clearly more experimental results are desirable. This paper presents measurements of the following new decay modes of the $\psi(2S)$: $\eta\beta\pi$, $\eta'3\pi$, $2(K^+K^-)$, $p\bar{p}K^+K^-$, $\Lambda\bar{\Lambda}\pi^+\pi^-$, $\bar{\Lambda}\bar{p}K^+$, $\Lambda\bar{p}K^+\pi^+\pi^-$, and more precise measurements of these previously measured modes: $2(\pi^+\pi^-)$, $2(\pi^+\pi^-)\pi^0$, $\omega\pi^+\pi^-$, $K^+K^-\pi^+\pi^-$, $\phi\pi^+\pi^-$, $\omega K^+K^-$, $\phi K^+K^-$, $p\bar{p}\pi^+\pi^-$, and $\Lambda\bar{\Lambda}$. We also measure $\omega\pi\bar{p}\bar{p}$ and obtain an improved upper limit for $\phi\pi\bar{p}\bar{p}$. Where applicable, the inclusion of charge conjugate modes is implied. Eleven of the modes we study have been previously observed at the $J/\psi$.

The data sample used in this analysis is obtained at the $\psi(2S)$ and the nearby continuum in $e^+e^-$ collisions produced by the Cornell Electron Storage Ring (CESR) and acquired with the CLEO detector. The CLEO III detector [7] features a solid angle coverage for charged and neutral particles of 93%. The charged particle tracking system, operating in a 1.0 T magnetic field along the beam axis, achieves a momentum resolution of $\sim 0.6\%$ at $p = 1$ GeV/c. The calorimeter attains a photon energy resolution of 2.2% at $E_\gamma = 1$ GeV and 5% at 100 MeV. Two particle identification systems, one based on energy loss ($dE/dx$) in the drift chamber and the other a ring-imaging Cherenkov (RICH) detector, are used together to separate $K^\pm$ from $\pi^\pm$. The combined $dE/dx$-RICH particle identification procedure has efficiencies exceeding 90% and misidentification rates below 5% for both $\pi^\pm$ and $K^\pm$.

Half of the $\psi(2S)$ data and all the continuum data were taken after a transition to the CLEO-c [8] detector configuration, in which CLEO III’s silicon-strip vertex detector was replaced with a six-layer all-stereo drift chamber. The two detector configurations also correspond to different accelerator lattices: the former with a single wiggler magnet and a center-of-mass energy spread of 1.5 MeV, the latter (CESR-c [8]) with six wiggler magnets and an energy spread of 2.3 MeV.

The integrated luminosity ($L$) of the datasets was measured using $\gamma\gamma$ events in the calorimeter [9]. Event counts were normalized with a Monte Carlo (MC) simulation based on the Babayaga [10] event generator combined with GEANT-based [11] detector modeling. The datasets consist of $L = 5.46$ pb$^{-1}$ on the peak of the $\psi(2S)$ (2.57 pb$^{-1}$ for CLEO III, 2.89 pb$^{-1}$ for CLEO-c) and 20.46 pb$^{-1}$ at $\sqrt{s} = 3.67$ GeV (all CLEO-c). The nominal scale
factor used to normalize continuum yields to $\psi(2S)$ data is $f_{\text{nom}} = 0.2645 \pm 0.004$, and is determined from the integrated luminosities of the data sets corrected for the $1/s$ dependence of the cross section, where the error is from the relative luminosity uncertainty. The actual $f$ used for each mode also corrects for the small differences in efficiency between the $\psi(2S)$ and continuum data samples.

Standard requirements are used to select charged particles reconstructed in the tracking system and photon candidates in the CsI calorimeter. We require tracks of charged particles to have momenta $p > 100$ MeV and to satisfy $|\cos \theta| < 0.90$, where $\theta$ is the polar angle with respect to the $e^+$ direction. Each photon candidate satisfies $E_\gamma > 30$ MeV and is more than 8 cm away from the projections of tracks into the calorimeter. Particle identification from $dE/dx$ and the RICH is used on all charged particle candidates. Pions, kaons, and protons must be positively and uniquely identified. That is: pions must not satisfy interpretation limits determined from MC studies: $dE/dx$ must not be identified as electrons using criteria based on momentum, calorimeter energy as kaons or protons, and kaons and protons obey similar requirements. Charged particles must be positively and uniquely identified. That is: pions must not satisfy interpretation as kaons or protons, and kaons and protons obey similar requirements. Charged particles must not be identified as electrons using criteria based on momentum, calorimeter energy deposition, and $dE/dx$.

The invariant mass of the decay products from the following particles must lie within limits determined from MC studies: $\pi^0$ ($M_{\gamma\gamma} = 120-150$ MeV), $\eta$ ($M_{\gamma\gamma} = 500-580$ MeV), $\eta$ ($M_{\pi^+\pi^-\pi^0} = 530-565$ MeV), $\omega$ ($M_{\pi^+\pi^-\pi^0} = 740-820$ MeV [$M_{\pi^+\pi^-\pi^0} = 760-800$ MeV for the $\omega p\bar{p}$ final state]), $\phi$ ($M_{K^+K^-} = 1.00 - 1.04$ GeV), and $\Lambda$ ($M_{\pi^+\pi^-\Lambda^0} = 1.1136 - 1.1180$ GeV). For $\pi^0 \to \gamma\gamma$ and $\eta \to \gamma\gamma$ candidates in events with more than two photons, the combination giving a mass closest to the known $\pi^0$ or $\eta$ mass is chosen, and a kinematically constrained fit to the known parent mass is used. Fake $\pi^0$'s and $\eta$'s are suppressed with lateral electromagnetic shower profile restrictions. For $\eta \to \pi^+\pi^-\pi^0$ and $\omega \to \pi^+\pi^-\pi^0$, the $\pi^0$ is selected as described above, and then combined with all possible combinations of two oppositely charged pions choosing the combination that is closest to the $\eta(\omega)$ mass. A kinematically constrained fit is used for neither of these modes, nor for $\phi$'s or for $\Lambda$'s. For $\Lambda \to p\pi^-$, a fit of the $p\pi^-$ trajectories to a common vertex separated from the $e^+e^-$ interaction ellipsoid is made. Contamination from $K_S$ decays is eliminated primarily by the energy and momentum requirements imposed on the event, and by particle identification.

Energy and momentum conservation requirements are imposed on the reconstructed final state hadrons, which have momentum $p_i$ and combined measured energy $E_{\text{vis}}$. We require the measured scaled energy $E_{\text{vis}}/E_{\text{cm}}$ be consistent with unity within experimental resolution, which varies by final state. We require $|\Sigma p_i|/E_{\text{cm}} < 0.02$. Together these requirements suppress backgrounds with missing energy or incorrect mass assignments. The experimental resolutions are smaller than 1% in scaled energy and 2% in scaled momentum.

For the final states $2(\pi^+\pi^-)\pi^0$, $\omega\pi^+\pi^-$, and $\omega K^+K^-$, an additional cut is applied to remove a background of radiative events. When the photon is combined with a low-energy photon signal, it can imitate a $\pi^0$. We require $(E_{\text{4tracks}} + E_\gamma)/E_{\text{cm}} < 0.995$, where $E_\gamma$ is the energy of the highest energy photon.

In order to compute $Q_h$ in modes with two or more charged pions, two $\pi^0$'s or an $\eta$, it is necessary to remove the contribution from the transitions $\psi(2S) \to J/\psi X$, where $X = \pi^+\pi^-$, $\pi^0\pi^0$, or $\eta$. Accordingly we reject events in which the mass of any of the following falls within the range $3.05 < m < 3.15$ GeV: the two highest momentum oppositely charged tracks, the recoil mass against the two lowest momentum oppositely charged tracks, or the mass recoiling against the two $\pi^0$'s or $\eta$.

For every final state, a signal selection range in $E_{\text{vis}}/E_{\text{cm}}$ is determined by Monte Carlo simulation, and a sideband selection range is defined to measure background. Final states
with the intermediate $\eta$, $\omega$, or $\phi$ particles must satisfy a scaled energy signal selection range requirement identical to the corresponding mode without the intermediate particle. For example, the scaled energy signal selection range is the same for $\phi K^+ K^-$ and $K^+ K^- K^+ K^-$. For final states with an $\eta$, $\omega$, or $\phi$, the event yield is determined from signal and sideband selection ranges of the intermediate particle mass. The scaled energy and mass signal and sideband selection ranges for $\psi(2S)$ and continuum data are identical, and are listed by mode in Tables I and II.

TABLE I: Signal and sideband selection ranges for the scaled energy, $E_{vis}/E_{cm}$, by mode.

| mode                   | signal (GeV) | sideband (GeV) |
|------------------------|--------------|----------------|
| $2(\pi^+\pi^-)$        | 0.98-1.02    | 0.96-0.98, 1.02-1.04 |
| $2(\pi^+\pi^-)\pi^0$  | 0.98-1.02    | 0.96-0.98, 1.02-1.04 |
| $K^+K^-\pi^+\pi^-$     | 0.99-1.01    | 0.98-0.99, 1.01-1.02 |
| $2(K^+K^-)$             | 0.99-1.01    | 0.98-0.99, 1.01-1.02 |
| $pp\pi^+\pi^-$         | 0.99-1.01    | 0.98-0.99, 1.01-1.02 |
| $ppK^+K^-$              | 0.99-1.01    | 0.98-0.99, 1.01-1.02 |
| $\Lambda\bar{\Lambda}$ | 0.99-1.01    | 0.98-0.99, 1.01-1.02 |
| $\Lambda\Lambda\pi^+\pi^-$ | 0.99-1.01 | 0.98-0.99, 1.01-1.02 |
| $\Lambda\bar{\Lambda}\pi^+$ | 0.99-1.01 | 0.98-0.99, 1.01-1.02 |
| $\Lambda\bar{\Lambda}\pi^+\pi^-$ | 0.99-1.01 | 0.98-0.99, 1.01-1.02 |

TABLE II: The mass signal and sideband selection ranges for modes with an $\eta$, $\omega$, or $\phi$. Modes with these particles must satisfy a scaled energy signal selection requirement identical to the corresponding mode without the intermediate particle.

| mode                   | Variable         | signal (GeV) | sideband (GeV) |

| $\phi pp$             | $m_{K^+K^-}$     | 1.00-1.04    | 1.04-1.08 |
Figures 1 and 2 show the distributions of $E_{vis}/E_{cm}$ and resonance mass, where relevant, for all final states. The $\psi(2S)$ data is represented by the points with error bars, the open histogram is signal Monte Carlo with arbitrary normalization, and the shaded histogram is the scaled continuum. The arrows indicate the scaled energy and resonance mass selection ranges. The requirements of energy and momentum conservation together with particle identification result in small backgrounds. The dominant background in most modes at the $\psi(2S)$ is from the continuum.

Event totals are shown for both the $\psi(2S)$ and the continuum in Table III where $S_{\psi(2S)} (S_{co})$ is the number of events in the signal region and $B_{\psi(2S)} (B_{co})$ the number of events in the sideband region in $\psi(2S)$ (continuum) data. Under the assumption that interference between $\psi(2S)$ decay and continuum production of the same final state is absent, the number of events attributable to each $\psi(2S)$ decay mode, $N_S$, is

$$N_S = S_{\psi(2S)} - B_{\psi(2S)} - f(S_{co} - B_{co}),$$  \hspace{1cm} (2)

where $f$ is mode dependent and listed in Table III. We observe a statistically significant signal in all modes except $\phi pp$. The signal with the least statistical significance is $\omega pp$ (4.7σ).

The efficiency, $\epsilon$, for each final state is the average obtained from MC simulations for both detector configurations; the two values are typically within a few percent (relative) to each other. No initial state radiation is included in the Monte Carlo, but final state radiation is accounted for. The efficiencies in Table III include the branching ratios for intermediate states.

We correct $N_S$ for the efficiency and normalize to the number of $\psi(2S) \rightarrow \pi^+\pi^- J/\psi$, $J/\psi \rightarrow \mu^+\mu^-$ decays in the data, which has been determined previously to be $(6.75 \pm 0.12) \times 10^4$, where the error accounts for data and MC statistics (0.7%) and for uncertainties in trigger efficiency (0.5%) and angular distributions (1.5%). Complete details may be found in [1]. The resulting relative branching ratios are listed in Table III. The absolute branching ratios are determined using $B(\psi(2S) \rightarrow \pi^+\pi^- J/\psi) = 0.323 \pm 0.013$ [1] and $B(J/\psi \rightarrow \mu^+\mu^-) = (5.88 \pm 0.10)\%$ [1]. $Q_h$ values are determined using the absolute $\psi(2S)$ branching ratios determined in this analysis and $J/\psi$ branching ratios from [1].

The systematic errors on the ratio of branching fractions share common contributions from the number of $\psi(2S) \rightarrow \pi^+\pi^- J/\psi$, $J/\psi \rightarrow \mu^+\mu^-$ decays (1.7%), uncertainty in $f$ (1.5%), trigger efficiency (1%), electron veto (1%), and Monte Carlo statistics (2%). Other sources vary by channel. We include the following contributions for detector performance modeling quality: charged particle tracking (3% per track), $\pi^0/\eta$ finding (4.4%), $\Lambda$ finding (3%), $\pi/K/p$ identification (1% identified $\pi/K/p$), and scaled energy and mass resolutions (2%). The systematic error associated with the uncertainty in the level of background is obtained by recomputing the branching ratio when the background at the $\psi(2S)$ and the continuum are coherently increased by 1σ. Since the background in many modes is small, the Poisson probability for the observed number of background events to fluctuate up to the 68% C.L. value is calculated and interpreted as the uncertainty in the level of background. The efficiencies were determined using events generated according to phase space. Many of the modes studied may have resonant submodes. A preliminary analysis finds the following prominent examples: $2(\pi^+\pi^-)$ where $\rho\pi\pi$ is dominant, $\omega\pi\pi$ where $b_1\pi$ is dominant and $\omega f_2(1270)$ is significant, $K^+K^-\pi^+\pi^-$ where $K^*(892)K\pi$ and $\rho K^+K^-$ are large and $\phi\pi\pi$ is small, and $\eta\phi\pi$ where $\eta\pi^0\rho$, $\eta\pi^+\pi^-$, and $\eta\rho\pi^+$ dominate. Allowing for the presence of resonant submodes changes the efficiency by less than 5% relative to the non-resonant efficiency for each mode we have studied. To account for this and the possibility of
FIG. 1: Distributions of the scaled visible energy $E_{\text{vis}}/E_{\text{cm}}$ for labeled final states. In each figure, entries are shown for $\psi(2S)$ data (points with error bars), signal Monte Carlo with arbitrary normalization (open histogram), and scaled continuum (shaded histogram). The vertical arrows indicate ends of signal selection ranges.
FIG. 2: Distributions of the intermediate particle mass for labeled final states. In each figure, entries are shown for $\psi(2S)$ data (points with error bars), signal Monte Carlo with arbitrary normalization (open histogram) and scaled continuum (shaded histogram). The vertical arrows indicate ends of signal selection ranges.

resonance polarization, we assign a 10% modeling systematic error to all modes. Systematic uncertainties are significant for all modes and the dominant error for many.

Figure 3 shows the branching ratios measured in this analysis and a comparison to previous measurements [1]. In Table IV, the values of $Q_h$ for those final states with measured branching ratios at the $J/\psi$ [1] are given. Figure 4 shows the $Q_h$ values from Table IV and a comparison to previous measurements. This is the first measurement of $Q_{\Lambda\bar{p}K}$. The values of $Q_h$ appear to be independent of the final state with no significant differences between
TABLE III: For each final state $h$: the number of events in the signal region, $S_{co}$, and background from sidebands, $B_{co}$, in continuum data; the scale factor, $f$; the number of events in the signal region, $S_{\psi(2S)}$, and background from sidebands, $B_{\psi(2S)}$, in $\psi(2S)$ data; the number of events attributable to $\psi(2S)$ decay, $N_S$, computed according to Equation (2); the average efficiency, $\varepsilon$; the ratio $B(\psi(2S) \to h)/B(\psi(2S) \to \pi^+\pi^- J/\psi, J/\psi \to \mu^+\mu^-)$ and the absolute branching fraction with statistical (68% C.L.) and systematic errors. For $\eta\bar{\psi}\pi$, the two decay modes $\eta \to \gamma\gamma$ and $\eta \to 3\pi$ are combined on line $\eta\bar{\psi}3\pi$. The branching ratios reported here explicitly exclude contributions from $\psi(2S) \to J/\psi X$, where $X = \pi^+\pi^-, \pi^0\pi^0, \text{or } \eta$.

mesonic and baryonic modes. The data indicates that $Q_h$ values are in general lower than the current leptonic ratio.

In summary, we have presented preliminary branching fractions for seven new decay modes of the $\psi(2S)$, namely $\eta\bar{\psi}\pi$, $\eta'\bar{\psi}\pi$, $2(K^+K^-)$, $p\bar{p}K^+K^-$, $\Lambda\bar{\Lambda}\pi^+\pi^-$, $\Lambda pK^+$, $\Lambda pK^+\pi^+\pi^-$, and more precise measurements of nine previously measured modes, which are $2(\pi^+\pi^-)$, $2(\pi^+\pi^-)\pi^0$, $\omega\pi^+\pi^-$, $K^+K^-\pi^+\pi^-$, $\phi\pi^+\pi^-$, $\omega K^+K^-$, $\phi K^+K^-$, $p\bar{p}\pi^+\pi^-$, and $\Lambda\Lambda$. We also measure $\omega p\bar{p}$ and obtain an improved upper limit for $\phi p\bar{p}$. Results are compared, where possible, with the corresponding $J/\psi$ branching ratios to test the 12% rule. This analysis is part of a comprehensive study of $\psi(2S)$ multi-body hadronic decays and their resonant substructure and is closely related to searches for non-$D\bar{D}$ decay modes of the $\psi(3770)$. Further results will be presented in the near future.
FIG. 3: A comparison of the measurements of the $\psi(2S)$ branching ratios for the labeled final states from this work (circles) and, when available, from the PDG [1] (triangles). The error bars are the quadrature sum of the statistical and systematic errors.

We gratefully acknowledge the effort of the CESR staff in providing us with excellent luminosity and running conditions. This work was supported by the National Science Foundation, the U.S. Department of Energy, the Research Corporation, and the Texas Advanced Research Program.
FIG. 4: A comparison of $Q_h$ values for the labeled final states determined from the $\psi(2S)$ branching ratios measured in this work (circles) and $J/\psi$ branching ratios from the PDG [1] to $Q_h$ values determined from the PDG [1] (triangles). The error bars are the quadrature sum of the statistical and systematic errors. The current value of $Q_l = (12.7 \pm 0.5)\%$ [1] is displayed as the vertical solid line. The vertical dashed lines are the $\pm 1\sigma$ uncertainty in $Q_l$. 

11
TABLE IV: For each final state $h$: the branching ratio from Table III, the corresponding branching ratio at the $J/\psi$ from [1], and $Q_h$ from Equation (1). The $\psi(2S)$ branching ratios and $Q_h$ explicitly exclude contributions from $\psi(2S) \to J/\psi X$ where $X = \pi^+\pi^-$, $\pi^0\pi^0$, or $\eta$.

[12] We do not veto $J/\psi$ from $\psi(2S) \to J/\psi\pi^0$ since it is a very small contribution as $B(\psi(2S) \to J/\psi\pi^0) = (9.6 \pm 2.1) \times 10^{-4}$.
