KAC-MOODY GROUPS AND CLUSTER ALGEBRAS

CHRISTOF GEISS, BERNARD LECLERC, AND JAN SCHRÖER

Abstract. Let \( Q \) be a finite quiver without oriented cycles, let \( \Lambda \) be the associated preprojective algebra, let \( g \) be the associated Kac-Moody Lie algebra with Weyl group \( W \), and let \( n \) be the positive part of \( g \). For each Weyl group element \( w \), a subcategory \( C_w \) of \( \text{mod}(\Lambda) \) was introduced by Buan, Iyama, Reiten and Scott. It is known that \( C_w \) is a Frobenius category and that its stable category \( C_w^{} \) is a Calabi-Yau category of dimension two. We show that \( C_w \) yields a cluster algebra structure on the coordinate ring \( \mathbb{C}[N(w)] \) of the unipotent group \( N(w) := N \cap (w^{-1} N \cdot w) \). Here \( N \) is the pro-unipotent pro-group with Lie algebra the completion \( \hat{n} \) of \( n \). One can identify \( \mathbb{C}[N(w)] \) with a subalgebra of \( U(n)^* \), the graded dual of the universal enveloping algebra \( U(n) \). Let \( S^* \) be the dual of Lusztig’s semicanonical basis \( S \) of \( U(n) \). We show that all cluster monomials of \( \mathbb{C}[N(w)] \) belong to \( S^* \), and that \( S^* \cap \mathbb{C}[N(w)] \) is a \( C \)-basis of \( \mathbb{C}[N(w)] \). Moreover, we show that the cluster algebra obtained from \( \mathbb{C}[N(w)] \) by formally inverting the generators of the coefficient ring is isomorphic to the algebra \( \mathbb{C}[N^w] \) of regular functions on the unipotent cell \( N^w \) of the Kac-Moody group with Lie algebra \( g \). We obtain a corresponding dual semicanonical basis of \( \mathbb{C}[N^w] \). As one application we obtain a basis for each acyclic cluster algebra, which contains all cluster monomials in a natural way.

1. Introduction

1.1. This is the continuation of an extensive project to obtain a better understanding of the relations between the following topics:

(i) Representation theory of quivers,
(ii) Representation theory of preprojective algebras,
(iii) Lusztig’s (semi)canonical basis of universal enveloping algebras,
(iv) Fomin and Zelevinsky’s theory of cluster algebras,
(v) Frobenius categories and 2-Calabi-Yau categories,
(vi) Cluster algebra structures on coordinate algebras of unipotent groups, Bruhat cells and flag varieties.

The topics (i) and (iii) are closely related. The numerous connections have been studied by many authors. Let us just mention Lusztig’s work on canonical bases of quantum groups, and Ringel’s Hall algebra approach to quantum groups. An important link between (ii) and (iii), due to Lusztig [Lu1, Lu2] and Kashiwara and Saito [KS] is that the elements of the (semi)canonical basis are naturally parametrized by the irreducible components of the varieties of nilpotent representations of a preprojective algebra.

Cluster algebras were invented by Fomin and Zelevinsky [BFZ, FZ2, FZ3], with the aim of providing a new algebraic and combinatorial setting for canonical bases and total positivity. One important breakthrough was the insight that the class of acyclic cluster algebras with a skew-symmetric exchange matrix can be categorified using the so-called cluster categories. Cluster categories were introduced by Buan, Marsh, Reineke, Reiten and Todorov [BMRRT], see also [Ke]. In a series of papers by some of these authors and also by Caldero and Keller [CK1, CK2], it was established that cluster categories have all necessary properties to provide the mentioned categorification. We refer to the nice overview article [BM] for more details on the development of this beautiful theory which established a strong connection between the topics (i), (iv) and (v). More recently, a different and more general type of categorification using representations of quivers with potentials was developed by Derksen, Weyman and Zelevinsky [DWZ1, DWZ2]. This provides another strong link between topics (i) and (iv).

In [GLS5] we showed that the representation theory of preprojective algebras Λ of Dynkin type (i.e. type A, D or E) is also closely related to cluster algebras. We proved that mod(Λ) can be regarded as a categorification of a natural (upper) cluster structure on the polynomial algebra C[N]. Here N is a maximal unipotent subgroup of a complex Lie group of the same type as Λ. Let n be its Lie algebra, and let U(n) be the universal enveloping algebra of n. The graded dual U(n)_{gr} can be identified with the coordinate algebra C[N]. By means of our categorification, we were able to prove that all the cluster monomials of C[N] belong to the dual of Lusztig’s semicanonical basis of U(n). Note that the cluster algebra C[N] is in general not acyclic.

The aim of this article is a vast generalization of these results to the more general setting of symmetric Kac-Moody groups and their unipotent cells. We also provide additional tools for studying the associated categories and cluster structures. For many cluster algebras we construct a basis (called dual semicanonical basis) which contains all cluster monomials in a natural way. In particular, we obtain such a basis for all acyclic cluster algebras. Also, we construct a dual PBW-basis of the cluster algebras involved. This provides another close link between Lie theory and the representation theory of preprojective algebras. We show that the coordinate rings C[N(w)] and C[N^w] are genuine cluster algebras in a natural way, and not just upper cluster algebras in the sense of [BFZ].
Let us give some more details. We consider preprojective algebras $\Lambda = \Lambda_Q$ attached to quivers $Q$ which are not necessarily of Dynkin type. These algebras are therefore infinite-dimensional in general. The category $\text{nil}(\Lambda)$ of all finite-dimensional nilpotent representations of $\Lambda$ is then too large to be related to a cluster algebra of finite rank. Moreover, it does not have projective or injective objects, and it lacks an Auslander-Reiten translation. However, Buan, Iyama, Reiten and Scott [BIRS] have attached to each element $w$ of the Weyl group $W = W_Q$ of $Q$ a subcategory $C_w$ of $\text{nil}(\Lambda)$. They show that the categories $C_w$ are Frobenius categories and the corresponding stable categories $\mathcal{C}_w$ are Calabi-Yau categories of dimension two. (These results were also discovered and proved independently in [GLS7] in the special case when $w$ is an adaptable element of $W$.) Each subcategory $C_w$ contains a distinguished maximal rigid $\Lambda$-module $V_i$ associated to each reduced expression $i = (i_1, \ldots, i_n)$ of $w$. (A module $X$ is called rigid if $\text{Ext}_\Lambda^1(X, X) = 0$.)

Special attention is given to the algebra $B_1 := \text{End}_{\Lambda}(V_i)^{\text{op}}$, which turns out to be quasi-hereditary. There is an equivalence between $\mathcal{C}_w$ and the category of $\Delta$-filtered $B_1$-modules. This allows us to describe mutations of maximal rigid $\Lambda$-modules in $\mathcal{C}_w$ in terms of the $\Delta$-dimension vectors of the corresponding $B_1$-modules.

To the subcategory $\mathcal{C}_w$ we associate a cluster algebra $\mathcal{A}(\mathcal{C}_w)$ which in general is not acyclic, and we show that $\mathcal{C}_w$ can be seen as a categorification of the cluster algebra $\mathcal{A}(\mathcal{C}_w)$. Each of the modules $V_i$ provides an initial seed of this cluster algebra. (As a very special case, we also obtain in this way a new categorification of every acyclic cluster algebra with a skew-symmetric exchange matrix and a certain choice of coefficients.) The proof relies on the fact that the algebra $\mathcal{A}(\mathcal{C}_w)$ has a natural realization as a certain subalgebra of the graded dual $U(n)^{t_gr}$, where $n$ is now the positive part of the symmetric Kac-Moody Lie algebra $\mathfrak{g} = \mathfrak{n}^+ \oplus \mathfrak{h} \oplus \mathfrak{n}$ of the same type as $\Lambda$. We show that again all the cluster monomials belong to the dual of Lusztig’s semicanonical basis of $U(n)$.

Next, we prove that $\mathcal{A}(\mathcal{C}_w)$ has a simple monomial basis coming from the objects of the additive closure $\text{add}(M_i)$, where $M_i = M_1 \oplus \cdots \oplus M_r$ is another $\Lambda$-module in $\mathcal{C}_w$ associated to a reduced expression $i$ of $w$. The modules $M_k$ are rigid, but $M_i$ is not rigid, except in some trivial cases. We call it the dual PBW-basis of $\mathcal{A}(\mathcal{C}_w)$, and regard it as a generalization (in the dual setting) of the bases of $U(n)$ constructed by Ringel in terms of quiver representations, when $\mathfrak{g}$ is finite-dimensional [R11]. We use this to prove that $\mathcal{A}(\mathcal{C}_w)$ is spanned by a subset of the dual semicanonical basis of $U(n)^{t_gr}$. Thus, we obtain a natural basis of $\mathcal{A}(\mathcal{C}_w)$ containing all the cluster monomials. We call it the dual semicanonical basis of $\mathcal{A}(\mathcal{C}_w)$. We prove that $\mathcal{A}(\mathcal{C}_w)$ is isomorphic to the coordinate ring of the finite-dimensional unipotent subgroup $N(w)$ of the symmetric Kac-Moody group attached to $\mathfrak{g}$. Moreover, we show that the cluster algebra obtained from $\mathcal{A}(\mathcal{C}_w)$ by formally inverting the generators of the coefficient ring is isomorphic to the algebra of regular functions on the unipotent cell $N^w$ of the Kac-Moody group. This solves Conjecture IV.3.1 of [BIRS].

Note also that in the Dynkin case the unipotent cells $N^w$ are closely related to the double Bruhat cells of type $(e, w)$, whose coordinate ring is known to be an upper cluster algebra by a result of [BFZ]. However, our proof is different and shows that $\mathcal{C}[N^w]$ is not only an upper cluster algebra but a genuine cluster algebra.

Finally, we explain how the results of this paper are related to those of [GLS6], in which a cluster algebra structure on the coordinate ring of the unipotent radical $N^w$ of a parabolic subgroup of a complex simple algebraic group of type $A, D, E$ was introduced. We give a proof of Conjecture 9.6 of [GLS6].
1.2. **Remark.** Our preprint [GLS7] contains special cases of the main results of this article: When $w$ is an adaptable Weyl group element, we constructed and studied the subcategories $C_w$ independently of [BIRS], using different methods. For this case, [GLS7] contains a proof of [BIRS, Conjecture IV.3.1]. Since [GLS7] is already cited in several published articles, we decided to keep it on the arXiv as a convenient reference, but it will not be published in a journal.

1.3. **Notation.** Throughout let $K$ be an algebraically closed field. For a $K$-algebra $A$ let $\text{mod}(A)$ be the category of finite-dimensional left $A$-modules. By a module we always mean a finite-dimensional left module. Often we do not distinguish between a module and its isomorphism class. Let $D := \text{Hom}_K(-,K): \text{mod}(A) \to \text{mod}(A^{\text{op}})$ be the usual duality.

For a quiver $Q$ let $\text{rep}(Q)$ be the category of finite-dimensional representations of $Q$ over $K$. It is well known that we can identify $\text{rep}(Q)$ and $\text{mod}(KQ)$.

By a subcategory we always mean a full subcategory. For an $A$-module $M$ let $\text{add}(M)$ be the subcategory of all $A$-modules which are isomorphic to finite direct sums of direct summands of $M$. A subcategory $\mathcal{U}$ of $\text{mod}(A)$ is an additive subcategory if any finite direct sum of modules in $\mathcal{U}$ is again in $\mathcal{U}$. By $\text{Fac}(M)$ (resp. $\text{Sub}(M)$) we denote the subcategory of all $A$-modules $X$ such that there exists some $t \geq 1$ and some epimorphism $M^t \to X$ (resp. monomorphism $X \to M^t$).

For an $A$-module $M$ let $\Sigma(M)$ be the number of isomorphism classes of indecomposable direct summands of $M$. An $A$-module is called basic if it can be written as a direct sum of pairwise non-isomorphic indecomposable modules.

For an $A$-module $M$ and a simple $A$-module $S$ let $[M:S]$ be the Jordan-Hölder multiplicity of $S$ in a composition series of $M$. Let $\dim(M) := \dim_A(M) := ([M:S])_S$ be the dimension vector of $M$, where $S$ runs through all isomorphism classes of simple $A$-modules.

For a set $U$ we denote its cardinality by $|U|$. If $f: X \to Y$ and $g: Y \to Z$ are maps, then the composition is denoted by $gf = g \circ f: X \to Z$.

If $U$ is a subset of a $K$-vector space $V$, then let $\text{Span}_K(U)$ be the subspace of $V$ generated by $U$.

By $K(X_1, \ldots, X_r)$ (resp. $K[X_1, \ldots, X_r]$) we denote the field of rational functions (resp. the polynomial ring) in the variables $X_1, \ldots, X_r$ with coefficients in $K$.

Let $\mathbb{C}$ be the field of complex numbers, and let $\mathbb{N} = \{0, 1, 2, \ldots\}$ be the natural numbers, including 0. Set $\mathbb{N}_1 := \mathbb{N} \setminus \{0\}$.

Recommended introductions to representation theory of finite-dimensional algebras and Auslander-Reiten theory are the books [ARS, ASS, GR, RG].

2. **Definitions and known results**

2.1. **Preprojective algebras and nilpotent varieties.** Let $Q = (Q_0, Q_1, s, t)$ be a finite quiver without oriented cycles. (As usual, $Q_0$ is the set of vertices, $Q_1$ is the set of arrows, an arrow $a \in Q_1$ starts in a vertex $s(a)$ and terminates in $t(a)$.) Let

$$\Lambda = \Lambda_Q = K\overline{Q}/(c)$$
be the associated preprojective algebra. We assume that $Q$ is connected and has vertices $Q_0 = \{1, \ldots, n\}$. Here $K$ is an algebraically closed field, $KQ$ is the path algebra of the double quiver $\bar{Q}$ of $Q$ which is obtained from $Q$ by adding to each arrow $a: i \to j$ in $Q$ an arrow $a^*: j \to i$ pointing in the opposite direction, and (c) is the ideal generated by the element

$$c = \sum_{a \in Q_1} (a^* a - aa^*).$$

Clearly, the path algebra $KQ$ is a subalgebra of $\Lambda$. Let $\pi_Q: \mod(\Lambda) \to \mod(KQ)$ be the corresponding restriction functor.

A $\Lambda$-module $M$ is called nilpotent if a composition series of $M$ contains only the simple modules $S_1, \ldots, S_n$ associated to the vertices of $Q$. Let $\nil(\Lambda)$ be the abelian category of finite-dimensional nilpotent $\Lambda$-modules.

Let $d = (d_1, \ldots, d_n) \in \mathbb{N}^n$. By

$$\text{rep}(Q, d) = \prod_{a \in Q_1} \Hom_K(K^{d_i(a)}, K^{d_i(a)})$$

we denote the affine space of representations of $Q$ with dimension vector $d$. Furthermore, let $\mod(\Lambda, d)$ be the affine variety of elements

$$(f_a, f_a^*)_{a \in Q_1} \in \prod_{a \in Q_1} \left( \Hom_K(K^{d_i(a)}, K^{d_i(a)}) \times \Hom_K(K^{d_i(a)}, K^{d_i(a)}) \right)$$

such that the following holds:

(i) For all $i \in Q_0$ we have

$$\sum_{a \in Q_1, s(a) = i} f_a^* f_a = \sum_{a \in Q_1, t(a) = i} f_a f_a^*.$$

By $\Lambda_d$ we denote the variety of all $(f_a, f_a^*)_{a \in Q_1} \in \mod(\Lambda, d)$ such that the following condition holds:

(ii) There exists some $N$ such that for each path $a_1 a_2 \cdots a_N$ of length $N$ in the double quiver $\bar{Q}$ of $Q$ we have $f_{a_1} f_{a_2} \cdots f_{a_N} = 0$.

(It is not difficult to check that $\Lambda_d$ is indeed an affine variety, namely for a fixed $d$ we can choose $N = d_1 + \cdots + d_n$ in condition (ii) above.) If $Q$ is a Dynkin quiver, then (ii) follows already from condition (i). One can regard (ii) as a nilpotency condition, which explains why the varieties $\Lambda_d$ are often called nilpotent varieties. Note that $\text{rep}(Q, d)$ can be considered as a subvariety of $\Lambda_d$. In fact $\text{rep}(Q, d)$ forms an irreducible component of $\Lambda_d$. Lusztig [Lu1, Section 12] proved that all irreducible components of $\Lambda_d$ have the same dimension, namely

$$\dim \text{rep}(Q, d) = \sum_{a \in Q_1} d_{s(a)} d_{t(a)}.$$

One can interpret $\Lambda_d$ as the variety of nilpotent $\Lambda$-modules with dimension vector $d$. The group

$$\GL_d = \prod_{i=1}^n \GL_{d_i}(K)$$

acts on $\mod(\Lambda, d), \Lambda_d$ and $\text{rep}(Q, d)$ by conjugation. Namely, for $g = (g_1, \ldots, g_n) \in \GL_d$ and $x = (f_a, f_a^*)_{a \in Q_1} \in \mod(\Lambda, d)$ define

$$g.x := (g_{t(a)} f_a g_{s(a)}^{-1}, g_{s(a)} f_a^* g_{t(a)}^{-1})_{a \in Q_1}.$$
The action on $\Lambda_d$ and $\text{rep}(Q, d)$ is obtained via restriction. The isomorphism classes of $\Lambda$-modules in $\text{mod}(\Lambda, d)$ and $\Lambda_d$, and $KQ$-modules in $\text{rep}(Q, d)$, respectively, correspond to the orbits of these actions. For a module $M$ in $\text{mod}(\Lambda, d)$, (resp. in $\Lambda_d$ or in $\text{rep}(Q, d)$), let $\text{GL}_d \cdot M$ denote its $\text{GL}_d$-orbit.

There is a bilinear form $\langle -, - \rangle = \langle -, - \rangle_Q : \mathbb{Z}^n \times \mathbb{Z}^n \to \mathbb{Z}$ associated to $Q$ defined by

$$\langle d, e \rangle := \langle d, e \rangle_Q := \sum_{i \in Q_0} d_i e_i - \sum_{a \in Q_1} d_{s(a)} e_{t(a)}.$$ 

The dimension vector of a $KQ$-module $M$ is denoted by $\dim (M) = \dim_Q (M)$. (Note that $\dim_Q (M) = \dim_{\Lambda} (M)$, since we can consider $M$ also as a $\Lambda$-module.) For $KQ$-modules $M$ and $N$ set

$$\langle M, N \rangle := \langle M, N \rangle_Q := \dim \text{Hom}_{KQ} (M, N) - \dim \text{Ext}^1_{KQ} (M, N).$$

It is known that $\langle M, N \rangle = \langle \dim (M), \dim (N) \rangle$. Let $(-, -) : \mathbb{Z}^n \times \mathbb{Z}^n \to \mathbb{Z}$ be the symmetrization of the bilinear form $\langle -, - \rangle$, i.e. $\langle d, e \rangle := \langle d, e \rangle + \langle e, d \rangle$. For $\Lambda$-modules $X$ and $Y$ set

$$\langle X, Y \rangle_Q := \langle \pi_Q (X), \pi_Q (Y) \rangle_Q + \langle \pi_Q (Y), \pi_Q (X) \rangle_Q.$$ 

**Lemma 2.1** ([CB, Lemma 1]). For any $\Lambda$-modules $X$ and $Y$ we have

$$\dim \text{Ext}^1_{\Lambda} (X, Y) = \dim \text{Hom}_{\Lambda} (X, Y) + \dim \text{Hom}_{\Lambda} (Y, X) - \langle X, Y \rangle_Q.$$ 

In particular, $\dim \text{Ext}^1_{\Lambda} (X, X)$ is even, and $\dim \text{Ext}^1_{\Lambda} (Y, X) = \dim \text{Ext}^1_{\Lambda} (Y, X)$.

**Corollary 2.2.** For a nilpotent $\Lambda$-module $X$ with dimension vector $d$ the following are equivalent:

- The closure $\text{GL}_d \cdot X$ of $\text{GL}_d \cdot X$ is an irreducible component of $\Lambda_d$;
- The orbit $\text{GL}_d \cdot X$ is open in $\Lambda_d$;
- $\text{Ext}^1_{\Lambda} (X, X) = 0$.

### 2.2. Semicanonical bases

We recall the definition of the dual semicanonical basis and its multiplicative properties, following [Lu1, Lu2, GLS1, GLS4]. From now on, assume that $K = \mathbb{C}$.

For each dimension vector $d = (d_1, \ldots, d_n)$ we defined the affine variety $\Lambda_d$. A subset $C$ of $\Lambda_d$ is said to be constructible if it is a finite union of locally closed subsets. For a $\mathbb{C}$-vector space $V$, a function

$$f : \Lambda_d \to V$$

is constructible if the image $f(\Lambda_d)$ is finite and $f^{-1}(m)$ is a constructible subset of $\Lambda_d$ for all $m \in V$.

The set of constructible functions $\Lambda_d \to \mathbb{C}$ is denoted by $M(\Lambda_d)$. This is a $\mathbb{C}$-vector space. Recall that the group $\text{GL}_d$ acts on $\Lambda_d$ by conjugation. By $M(\Lambda_d)^{\text{GL}_d}$ we denote the subspace of $M(\Lambda_d)$ consisting of the constructible functions which are constant on the $\text{GL}_d$-orbits in $\Lambda_d$. Set

$$\widehat{\mathcal{M}} := \bigoplus_{d \in \mathbb{N}^n} M(\Lambda_d)^{\text{GL}_d}.$$ 

For $f' \in M(\Lambda_d)^{\text{GL}_d}$, $f'' \in M(\Lambda_{d''})^{\text{GL}_{d''}}$ and $d = d' + d''$ we define a constructible function

$$f := f' \star f'' : \Lambda_d \to \mathbb{C}$$

in $M(\Lambda_d)^{\text{GL}_d}$ by

$$f(X) := \sum_{m \in \mathbb{C}} m \chi_c \left( \{ U \subseteq X \mid f'(U)f''(X/U) = m \} \right)$$

for $X \subseteq \Lambda_d$. For a function $f : \Lambda_d \to \mathbb{C}$ we define $\chi_f : \Lambda_d \to \mathbb{C}$ by $\chi_f(X) := f(X)$ for $X \subseteq \Lambda_d$.

The group $\text{GL}_d$ acts on the set $\text{GL}_d \cdot \mathcal{M}$ by

$$g \cdot f(x) := f(g^{-1}x)$$

for $g \in \text{GL}_d$, $f \in \mathcal{M}$ and $x \in \Lambda_d$.
for all $X \in \Lambda_d$, where $U$ runs over the points of the Grassmannian of all submodules of $X$ with $\dim(U) = d'$. Here, for a constructible subset $V$ of a complex variety we denote by $\chi_c(V)$ its (topological) Euler characteristic with respect to cohomology with compact support. This turns $\tilde{M}$ into an associative $\mathbb{C}$-algebra.

Remark 2.3. Note that the product $\star$ defined here is opposite to the convolution product we have used in [GLS1, GLS3, GLS4]. This new convention turns out to be better adapted to our choice of categorifying $\mathbb{C}[N(w)]$ and $\mathbb{C}[N^w]$ by categories closed under factor modules. It is also compatible with our choice in [GLS6] of categorifying coordinate rings of partial flag varieties by categories closed under submodules.

For the canonical basis vector $e_i := \dim(S_i)$ we know that $\Lambda_{e_i}$ is just a point, which (as a $\Lambda$-module) is isomorphic to the simple module $S_i$. Define $1_i : \Lambda_{e_i} \to \mathbb{C}$ by $1_i(S_i) := 1$.

By $M$ we denote the subalgebra of $\tilde{M}$ generated by the functions $1_i$ where $1 \leq i \leq n$. Set $M_d := M \cap M(\Lambda_d)^{GL_d}$. It follows that

$$M = \bigoplus_{d \in \mathbb{N}^n} M_d$$

is an $\mathbb{N}^n$-graded $\mathbb{C}$-algebra. Let $U(n)$ be the enveloping algebra of the positive part $n$ of the Kac-Moody Lie algebra $\mathfrak{g}$ associated to $Q$, see Sections 4.1 and 4.2.

Theorem 2.4 (Lusztig [Lu2]). There is an isomorphism of $\mathbb{N}^n$-graded $\mathbb{C}$-algebras

$$U(n) \to M$$

defined by $E_i \mapsto 1_i$ for $1 \leq i \leq n$.

Let $\text{Irr}(\Lambda_d)$ be the set of irreducible components of $\Lambda_d$.

Theorem 2.5 (Lusztig [Lu2]). For each $Z \in \text{Irr}(\Lambda_d)$ there is a unique $f_Z : \Lambda_d \to \mathbb{C}$ in $M_d$ such that $f_Z$ takes value 1 on some dense open subset of $Z$ and value 0 on some dense open subset of any other irreducible component $Z'$ of $\Lambda_d$. Furthermore, the set

$$S := \{f_Z \mid Z \in \text{Irr}(\Lambda_d), d \in \mathbb{N}^n\}$$

is a $\mathbb{C}$-basis of $M$.

The basis $S$ is called the semicanonical basis of $M$. By Theorem 2.4 we just identify $M$ and $U(n)$ and consider $S$ also as a basis of $U(n)$. Since $U(n)$ is a cocommutative Hopf algebra, its graded dual

$$U(n)^*_{\text{gr}} = \bigoplus_{d \in \mathbb{N}^n} U^*_d$$

is a commutative $\mathbb{C}$-algebra. Let $M^*_d$ be the dual space of $M_d$, and set

$$M^* := \bigoplus_{d \in \mathbb{N}^n} M^*_d.$$  

Again we identify $M^*$ and $U(n)^*_{\text{gr}}$.

For $X \in \Lambda_d$ define an evaluation function

$$\delta_X : M_d \to \mathbb{C}$$

by $\delta_X(f) := f(X)$.

It is not difficult to show that the map $X \mapsto \delta_X$ from $\Lambda_d$ to $M^*_d$ is constructible in the above sense. So on every irreducible component $Z \in \text{Irr}(\Lambda_d)$ there is a Zariski open set
on which this map is constant. Define $\rho_Z := \delta_X$ for any $X$ in this open set. The $\mathbb{C}$-vector space $M_d^*$ is spanned by the functions $\delta_X$ with $X \in \Lambda_d$. Then by construction

$$S^* := \{\rho_Z \mid Z \in \text{Irr}(\Lambda_d), d \in \mathbb{N}^n\}$$

is the basis of $\mathcal{M}^* \equiv U(n)_{gr}^*$ dual to Lusztig’s semicanonical basis $\mathcal{S}$ of $U(n)$.

In case $X$ is a rigid $\Lambda$-module, the orbit of $X$ in $\Lambda_d$ is open, its closure is an irreducible component $Z$, and $\delta_X = \rho_Z$ belongs to $S^*$.

For a module $X \in \Lambda_d$ and an $m$-tuple $i = (i_1, \ldots, i_m)$ with $1 \leq i_j \leq n$ for all $j$, let $F_{i,X}$ denote the projective variety of composition series of type $i$ of $X$. Thus an element in $F_{i,X}$ is a flag

$$(0 = X_0 \subset X_1 \subset \cdots \subset X_m = X)$$

of submodules $X_j$ of $X$ such that for all $1 \leq j \leq m$ the subfactor $X_j/X_{j-1}$ is isomorphic to the simple $\Lambda$-module $S_{i_j}$ associated to the vertex $i_j$ of $Q$. Let

$$d_i : \Lambda_d \to \mathbb{C}$$

be the map which sends $X \in \Lambda_d$ to $\chi_c(F_{i,X})$. It follows from the definition of $\star$ that $d_i = 1_{i_1} \star \cdots \star 1_{i_m}$. The $\mathbb{C}$-vector space $\mathcal{M}_d$ is spanned by the maps $d_i$. We have $\delta_X(d_i) = \chi_c(F_{i,X}).$

**Theorem 2.6 (GLS1).** For $X, Y \in \text{nil}(\Lambda)$ we have $\delta_X \delta_Y = \delta_{X \oplus Y}$.

In [GLS1] a more complicated formula than the one in Theorem 2.6 is given, expressing $\delta_X \delta_Y$ as a linear combination of $\delta_Z$ where $Z$ runs over all possible middle terms of non-split short exact sequences with end terms $X$ and $Y$. The formula is especially useful when $\dim \text{Ext}^1_\Lambda(X, Y) = 1$. In this case, the following hold:

**Theorem 2.7 (GLS1 Theorem 2]).** Let $X, Y \in \text{nil}(\Lambda)$. If $\dim \text{Ext}^1_\Lambda(X, Y) = 1$ with

$$0 \to X \to E' \to Y \to 0 \quad \text{and} \quad 0 \to Y \to E'' \to X \to 0$$

the corresponding non-split short exact sequences, then

$$\delta_X \delta_Y = \delta_{E'} + \delta_{E''}.$$

2.3. Frobenius categories. Let $A$ be a $K$-algebra. Let $\mathcal{C}$ be a subcategory of a module category $\mathcal{M}(A)$ which is closed under extensions. Clearly, we have

$$\text{Ext}^2_A(X, Y) = \text{Ext}^3_\Lambda(X, Y)$$

for all modules $X$ and $Y$ in $\mathcal{C}$. An $A$-module $C$ in $\mathcal{C}$ is called $\mathcal{C}$-projective (resp. $\mathcal{C}$-injective) if $\text{Ext}^1_A(C, X) = 0$ (resp. $\text{Ext}^1_\Lambda(X, C) = 0$) for all $X \in \mathcal{C}$. If $C$ is $\mathcal{C}$-projective and $\mathcal{C}$-injective, then $C$ is also called $\mathcal{C}$-projective-injective. We say that $\mathcal{C}$ has enough projectives (resp. enough injectives) if for each $X \in \mathcal{C}$ there exists a short exact sequence $0 \to Y \to C \to X \to 0$ (resp. $0 \to X \to C \to Y \to 0$) where $C$ is $\mathcal{C}$-projective (resp. $\mathcal{C}$-injective) and $Y \in \mathcal{C}$. If $\mathcal{C}$ has enough projectives and enough injectives, and if these coincide (i.e., an object is $\mathcal{C}$-projective if and only if it is $\mathcal{C}$-injective), then $\mathcal{C}$ is called a Frobenius subcategory of $\text{mod}(A)$. In particular, $\mathcal{C}$ is a Frobenius category in the sense of Happel [Ha1]. Of course, for $A = \Lambda$, an $A$-module $C$ in $\mathcal{C}$ is $\mathcal{C}$-projective if and only if it is $\mathcal{C}$-injective, see Lemma 2.1.

By definition the objects in the stable category $\underline{\mathcal{C}}$ are the same as the objects in $\mathcal{C}$, and the morphism spaces $\text{Hom}_\mathcal{C}(X, Y)$ are the morphism spaces in $\mathcal{C}$ modulo morphisms factoring through $\mathcal{C}$-projective-injective objects. The category $\underline{\mathcal{C}}$ is a triangulated category in a natural way $[\text{H}a1]$, where the shift is given by the relative inverse syzygy functor

$$\Omega^{-1} : \mathcal{C} \to \underline{\mathcal{C}}.$$
For all $X$ and $Y$ in $\mathcal{C}$ there is a functorial isomorphism 
\[ \text{Hom}_\mathcal{C}(X, \Omega^{-1}(Y)) \cong \text{Ext}_\mathcal{C}^1(X, Y). \]

The category $\mathcal{C}$ is a 2-Calabi-Yau category, if for all $X, Y \in \mathcal{C}$ there is a functorial isomorphism 
\[ \text{Ext}_\mathcal{C}^1(X, Y) \cong D\text{Ext}_\mathcal{C}^1(Y, X). \]

2.4. Frobenius categories associated to Weyl group elements. By $\hat{I}_1, \ldots, \hat{I}_n$ we denote the indecomposable injective $\Lambda$-modules with socle $S_1, \ldots, S_n$, respectively. Here $S_1, \ldots, S_n$ are the 1-dimensional simple $\Lambda$-modules corresponding to the vertices of the quiver $Q$. (The modules $\hat{I}_i$ are infinite-dimensional if $Q$ is not a Dynkin quiver.)

For a $\Lambda$-module $X$ and a simple module $S_j$ let $\text{soc}_{(j_1)}(X) := \text{soc}_{S_j}(X)$ be the sum of all submodules $U$ of $X$ with $U \cong S_j$. (In this definition, we do not assume that $X$ is finite-dimensional.) For a sequence $(j_1, \ldots, j_t)$ of indices with $1 \leq j_p \leq n$ for all $p$, there is a unique chain 
\[ 0 = X_0 \subseteq X_1 \subseteq \cdots \subseteq X_t \subseteq X \]
of submodules of $X$ such that $X_{p}/X_{p-1} = \text{soc}_{(j_p)}(X/X_{p-1})$. Define $\text{soc}_{(j_1, \ldots, j_t)}(X) := X_t$.

For the rest of this section, let $i = (i_r, \ldots, i_1)$ be a reduced expression of an element $w$ of the Weyl group $W = W_Q$ of $Q$. (By definition, this is the Weyl group of the Kac-Moody Lie algebra $\mathfrak{g}$ associated to $Q$, see Section [H]) For $1 \leq k \leq r$ let 
\[ V_k := V_{i_k} := \text{soc}_{(i_k, \ldots, i_1)}(\hat{I}_{i_k}), \]
and set $V_i := V_1 \oplus \cdots \oplus V_p$. (The module $V_i$ is dual to the cluster-tilting object constructed in [BIRS] Section III.2.) Define 
\[ \mathcal{C}_i := \text{Fac}(V_i) \subseteq \text{nil}(\Lambda). \]

For $1 \leq j \leq n$ let $k_j := \max\{1 \leq k \leq r \mid i_k = j\}$. Define $I_{i,j} := V_{i,k_j}$ and set 
\[ I_i := I_{i,1} \oplus \cdots \oplus I_{i,n}. \]
The category $\mathcal{C}_i$ and the module $I_i$ depend only on $w$, and not on the chosen reduced expression $i$ of $w$. Therefore, we define 
\[ \mathcal{C}_w := \mathcal{C}_i \text{ and } I_w := I_i. \]

(If $Q$ is a Dynkin quiver, and $w = w_0$ is the longest Weyl group element, then $\mathcal{C}_w = \text{nil}(\Lambda) = \text{mod}(\Lambda)$.) Without loss of generality, we assume that for each $1 \leq j \leq n$ there is some $1 \leq k \leq r$ with $i_k = j$. Otherwise, we could just replace $Q$ by a quiver with fewer vertices. Note also that $\mathcal{C}_w = \text{add}(I_w)$ if and only if $i_k \neq i_s$ for all $k \neq s$. In this case, most of our theory becomes trivial.

The following three theorems are proved in [BIRS]. They were also obtained independently and by different methods in [GLS] in the case when $w$ is adaptable.

**Theorem 2.8.** For any Weyl group element $w$ the following hold:

(i) $\mathcal{C}_w$ is a Frobenius category;
(ii) The stable category $\mathcal{C}_w$ is a 2-Calabi-Yau category;
(iii) $\mathcal{C}_w$ has $n$ indecomposable $\mathcal{C}_w$-projective-injective modules, namely the indecomposable direct summands of $I_w$;
(iv) $\mathcal{C}_w = \text{Fac}(I_w)$. 
We denote the relative inverse syzygy functor of $\mathcal{C}_w$ by $\Omega_{w}^{-1}$.

Recall that a $\Lambda$-module $T$ is rigid if $\text{Ext}^1_{\Lambda}(T, T) = 0$. Let $\mathcal{C}$ be a subcategory of $\text{mod}(\Lambda)$, and let $T \in \mathcal{C}$ be rigid. Recall that for all $X, Y \in \text{mod}(\Lambda)$ we have $\dim \text{Ext}^1_{\Lambda}(X, Y) = \dim \text{Ext}^1_{\Lambda}(Y, X)$. We need the following definitions:

- $T$ is $\mathcal{C}$-maximal rigid if $\text{Ext}^1_{\Lambda}(T \oplus X, X) = 0$ with $X \in \mathcal{C}$ implies $X \in \text{add}(T)$;
- $T$ is a $\mathcal{C}$-cluster-tilting module if $\text{Ext}^1_{\Lambda}(T, X) = 0$ with $X \in \mathcal{C}$ implies $X \in \text{add}(T)$.

**Theorem 2.9.** For a rigid $\Lambda$-module $T$ in $\mathcal{C}_w$ the following are equivalent:

- (i) $\Sigma(T) = \text{length}(w)$;
- (ii) $T$ is $\mathcal{C}_w$-maximal rigid;
- (iii) $T$ is a $\mathcal{C}_w$-cluster-tilting module.

For $1 \leq k \leq r$ let

$$k^- := \max \{0, 1 \leq s \leq k - 1 \mid i_s = i_k\},$$

$$k^+ := \min \{k + 1 \leq s \leq r, r + 1 \mid i_s = i_k\}.$$

For $1 \leq i, j \leq n$ let $q_{ij}$ be the number of edges between the vertices $i$ and $j$ of the underlying graph of our quiver $Q$.

Following Berenstein, Fomin and Zelevinsky we define a quiver $\Gamma_1$ as follows: The vertices of $\Gamma_1$ are just the numbers $1, \ldots, r$. For $1 \leq s, t \leq r$ there are $q_{si,ti}$ arrows from $s$ to $t$ provided $t^+ \geq s^+ > t > s$. These are called the ordinary arrows of $\Gamma_1$. Furthermore, for each $1 \leq s \leq r$ there is an arrow $s \to s^-$ provided $s^- > 0$. These are the horizontal arrows of $\Gamma_1$.

On the other hand, let $A$ be a $K$-algebra, and let $X = X_1^{n_1} \oplus \cdots \oplus X_r^{n_r}$ be a finite-dimensional $A$-module, where the $X_i$ are pairwise non-isomorphic indecomposable modules and $n_i \geq 1$. Let $S_i = S_{X_i}$ be the simple $\text{End}_A(X)^{\text{op}}$-module corresponding to $X_i$. Then $\text{Hom}_A(X, X_i)$ is the indecomposable projective $\text{End}_A(X)^{\text{op}}$-module with top $S_i$. The basic facts on the quiver $\Gamma_X$ of the endomorphism algebra $\text{End}_A(X)^{\text{op}}$ are collected in [GLS5 Section 3.2]. In particular, we have a 1-1 correspondence between the vertices of $\Gamma_X$ and the modules $X_1, \ldots, X_r$.

**Theorem 2.10.** The module $V_i$ is $\mathcal{C}_w$-maximal rigid, and we have $\Gamma_{V_i} = \Gamma_1$.

For example, let $Q$ be a quiver with underlying graph $\begin{array}{c} 1 \rightarrow 2 \rightarrow 3. \end{array}$ Then $i := (i_7, \ldots, i_1) := (3, 1, 2, 3, 1, 2, 1)$ is a reduced expression of a Weyl group element $w \in W_Q$. The quiver $\Gamma_1$ looks as follows:

![Quiver diagram](image)

We often try to visualize $\Lambda$-modules. For example, let $Q$ be the quiver

![Second quiver diagram](image)
and let $i := (i_6, \ldots, i_1) := (3, 2, 1, 3, 2, 1)$. Then the $\Lambda$-module $V_i = V_1 \oplus \cdots \oplus V_6$ looks as follows:

\[
\begin{align*}
V_1 &= 1 \\
V_2 &= 2^1 \\
V_3 &= 1^3 2^1 \\
V_4 &= 2^1 3^2 \\
V_5 &= 1^3 2^1 3^2 \\
V_6 &= 2^1 3^2 1^3 2^1
\end{align*}
\]

The numbers can be interpreted as basis vectors or as composition factors. For example, the module $V_5$ is a 9-dimensional $\Lambda$-module with dimension vector $\dim(\Lambda)(V_5) = (d_1, d_2, d_3) = (4, 3, 2)$. More precisely, one could display $V_5$ as follows:

This picture shows how the different arrows of the quiver $Q$ of $\Lambda$ act on the 9 basis vectors of $V_5$. For example, one can see immediately that the socle of $X$ is isomorphic to $S_2$, and the top is isomorphic to $S_1 \oplus S_1 \oplus S_1$.

### 2.5. Relative homology for $C_w$.

We recall some notions from relative homology theory which, for Artin algebras, was developed by Auslander and Solberg [AS1, AS2].

Let $A$ be a $K$-algebra, and let $X, Y, Z, T \in \mod(A)$. Set

\[F_T := \Hom(A, (T, -)) : \mod(A) \to \mod(\End_A(T)^{op}).\]

A short exact sequence

\[0 \to Z \to Y \to X \to 0\]

is $F_T$-exact if $0 \to F_T(Z) \to F_T(Y) \to F_T(X) \to 0$ is exact. By $F_T(X, Z)$ we denote the set of equivalence classes of $F_T$-exact sequences with end terms $X$ and $Z$ as above.

Let $\mathcal{Y}_T$ be the subcategory of all $X \in \mod(A)$ such that there exists an exact sequence

\[\cdots \to T_3 \xrightarrow{f_3} T_2 \xrightarrow{f_2} T_1 \xrightarrow{f_1} T_0 \xrightarrow{f_0} X \to 0\]  \hspace{1cm} (1)

where $T_i \in \add(T)$ for all $i$ and the short exact sequences

\[0 \to \Ker(f_i) \to T_i \to \Im(f_i) \to 0\]

are $F_T$-exact for all $i \geq 0$. We call sequence (1) an $\add(T)$-resolution of $X$. We say that (1) has length at most $d$ if $T_j = 0$ for all $j > d$. Note that

\[\add(T) \subseteq \mathcal{Y}_T.\]

Dually, one defines $\add(T)$-coresolutions

\[0 \to X \xrightarrow{g_0} T_0 \xrightarrow{g_1} T_1 \xrightarrow{g_2} T_2 \xrightarrow{g_3} \cdots\]

where we require now that the sequences

\[0 \to \Im(g_i) \to T_i \to \Coker(g_i) \to 0\]
are $F^T$-exact, where $F^T$ is the contravariant functor $\text{Hom}_A(-,T)$.

For $X \in \mathcal{Y}_T$ and $Z \in \text{mod}(A)$ let $\text{Ext}^i_{F^T}(X,Z)$, $i \geq 0$ be the cohomology groups of the cocomplex obtained by applying the functor $\text{Hom}_A(-,Z)$ to the sequence
$$\cdots \xrightarrow{f_3} T_2 \xrightarrow{f_2} T_1 \xrightarrow{f_1} T_0.$$  

**Lemma 2.11** ([AS1]). For $X \in \mathcal{Y}_T$ and $Z \in \text{mod}(A)$ there is a functorial isomorphism $\text{Ext}^1_{F^T}(X,Z) \cong F^T(X,Z)$.

**Proposition 2.12** ([AS2, Proposition 3.7]). For $X \in \mathcal{Y}_T$ and $Z \in \text{mod}(A)$ there is a functorial isomorphism $\text{Ext}^i_{F^T}(X,Z) \rightarrow \text{Ext}^i_{\text{End}_A(T)^{\text{op}}}(\text{Hom}_A(T,X),\text{Hom}_A(T,Z))$ for all $i \geq 0$.

**Corollary 2.13.** The functor $\text{Hom}_A(T,-) : \mathcal{Y}_T \rightarrow \text{mod}(\text{End}_A(T)^{\text{op}})$ is fully faithful. In particular, $\text{Hom}_A(T,-)$ has the following properties:

(i) If $X \in \mathcal{Y}_T$ is indecomposable, then $\text{Hom}_A(T,X)$ is indecomposable;
(ii) If $\text{Hom}_A(T,X) \cong \text{Hom}_A(T,Y)$ for some $X,Y \in \mathcal{Y}_T$, then $X \cong Y$.

Note that Corollary 2.13 follows already from [Au, Section 3], see also [APR, Lemma 1.3 (b)].

**Corollary 2.14.** Let $T \in \text{mod}(A)$, and let $C$ be an extension closed subcategory of $\mathcal{Y}_T$. If
$$\psi : 0 \rightarrow \text{Hom}_A(T,X) \xrightarrow{f} \text{Hom}_A(T,Y) \xrightarrow{g} \text{Hom}_A(T,Z) \rightarrow 0$$
is a short exact sequence of $\text{End}_A(T)^{\text{op}}$-modules with $X,Y,Z \in C$, then
$$\eta : 0 \rightarrow X \xrightarrow{f} Y \xrightarrow{g} Z \rightarrow 0$$
is a short exact sequence in $\text{mod}(A)$.

Now we apply the above ideas to the category $\mathcal{C}_w$. The following proposition is proved in [GLS7] for adaptable $w$ and in [BIRS] for arbitrary $w$. In a more general framework it is proved in [KR].

**Proposition 2.15.** Let $T$ be a $\mathcal{C}_w$-maximal rigid module, and let $X \in \mathcal{C}_w$. Then there exists an $\text{add}(T)$-resolution of the form
$$0 \rightarrow T_1 \rightarrow T_0 \rightarrow X \rightarrow 0$$
and an $\text{add}(T)$-coresolution of the form
$$0 \rightarrow X \rightarrow T'_1 \rightarrow T'_0 \rightarrow 0.$$

**Corollary 2.16.** For each $\mathcal{C}_w$-maximal rigid module $T$ we have $\mathcal{C}_w \subseteq \mathcal{Y}_T$.

**Corollary 2.17.** For each $X \in \mathcal{C}_w$ the projective dimension of the $\text{End}_A(T)^{\text{op}}$-module $\text{Hom}_A(T,X)$ is at most one.

**Corollary 2.18** ([Iy, Theorem 5.3.2]). If $T$ and $R$ are $\mathcal{C}_w$-maximal rigid $\Lambda$-modules, then the $\text{End}_A(T)^{\text{op}}$-module $\text{Hom}_A(T,R)$ is a classical tilting module, and
$$\text{End}_{\text{End}_A(T)^{\text{op}}}(\text{Hom}_A(T,R)) \cong \text{End}_A(R).$$
2.6. **The cluster algebra** $\mathcal{A}(C_w, T)$. We refer to [FZ1] for an excellent survey on cluster algebras. Here we only recall the main definitions and introduce a cluster algebra $\mathcal{A}(C_w, T)$ associated to a Weyl group element $w$ and a $C_w$-maximal rigid $\Lambda$-module $T$.

If $\tilde{B} = (b_{ij})$ is any $r \times (r - n)$-matrix with integer entries, then the **principal part** $B$ of $\tilde{B}$ is obtained from $\tilde{B}$ by deleting the last $n$ rows. Given some $1 \leq k \leq r - n$ define a new $r \times (r - n)$-matrix $\mu_k(\tilde{B}) = (b'_{ij})$ by

$$b'_{ij} = \begin{cases} 
-b_{ij} & \text{if } i = k \text{ or } j = k, \\
\frac{|b_{ik}b_{kj} + b_{ik}b_{kj}|}{2} & \text{otherwise},
\end{cases}$$

where $1 \leq i \leq r$ and $1 \leq j \leq r - n$. One calls $\mu_k(\tilde{B})$ a **mutation** of $\tilde{B}$. If $\tilde{B}$ is an integer matrix whose principal part is skew-symmetric, then it is easy to check that $\mu_k(\tilde{B})$ is also an integer matrix with skew-symmetric principal part. In this case, Fomin and Zelevinsky define a cluster algebra $\mathcal{A}(\tilde{B})$ as follows. Let $\mathcal{F} = \mathbb{C}(y_1, \ldots, y_r)$ be the field of rational functions in $r$ commuting variables $y_1, \ldots, y_r$. Define $y := (y_1, \ldots, y_r)$. One calls $(y, \tilde{B})$ the **initial seed** of $\mathcal{A}(\tilde{B})$. For $1 \leq k \leq r - n$ define

$$y^*_k := \prod_{b_{ik} > 0} y_i^{b_{ik}} + \prod_{b_{ik} < 0} y_i^{-b_{ik}} y_k.$$

The pair $(\mu_k(y), \mu_k(\tilde{B}))$, where $\mu_k(y)$ is obtained from $y$ by replacing $y_k$ by $y_k^*$, is the **mutation in direction** $k$ of the seed $(y, \tilde{B})$.

Now one can iterate this process of mutation and obtain inductively a set of seeds. Thus each seed consists of an $r$-tuple of algebraically independent elements of $\mathcal{F}$ called a **cluster** and of a matrix called the **exchange matrix**. The elements of a cluster are its **cluster variables**. Given a cluster $(f_1, \ldots, f_r)$, the monomials $f_1^{m_1}f_2^{m_2}\cdots f_r^{m_r}$ where $m_k \geq 0$ for all $k$ are called **cluster monomials**. A seed has $r - n$ neighbours obtained by mutation in direction $1 \leq k \leq r - n$. One does not mutate the last $n$ elements of a cluster, they serve as "coefficients" and belong to every cluster. The **cluster algebra** $\mathcal{A}(\tilde{B})$ is by definition the subalgebra of $\mathcal{F}$ generated by the set of all cluster variables appearing in all seeds obtained by iterated mutation starting with the initial seed.

It is often convenient to define a cluster algebra using an oriented graph, as follows. Let $\Gamma$ be a quiver without loops or 2-cycles with vertices $\{1, \ldots, r\}$. We can define an $r \times r$-matrix $B(\Gamma) = (b_{ij})$ by setting

$$b_{ij} = (\text{number of arrows } j \to i \text{ in } \Gamma) - (\text{number of arrows } i \to j \text{ in } \Gamma).$$

Let $B(\Gamma)^{\circ}$ be the $r \times (r - n)$-matrix obtained by deleting the last $n$ columns of $B(\Gamma)$. The principal part of $B(\Gamma)^{\circ}$ is skew-symmetric, hence this yields a cluster algebra $\mathcal{A}(B(\Gamma)^{\circ})$.

We apply this procedure to our subcategory $C_w$. Let $T = T_1 \oplus \cdots \oplus T_r$ be a basic $C_w$-maximal rigid $\Lambda$-module with $T_k$ indecomposable for all $k$. Without loss of generality assume that $T_{r - n + 1}, \ldots, T_r$ are $\Lambda$-projective-injective. By $T$ we denote the quiver of the endomorphism algebra $\text{End}_\Lambda(T)^{op}$. We then define the cluster algebra

$$\mathcal{A}(C_w, T) := \mathcal{A}(B(T)^{\circ}).$$

In particular, we denote by $\mathcal{A}(C_w)$ the cluster algebra $\mathcal{A}(C_w, V_1)$ attached to the $C_w$-maximal rigid module $V_1$ of Section 2.3. Thus $\mathcal{A}(C_w) := \mathcal{A}(B(\Gamma_1)^{\circ})$. (Up to isomorphism of cluster algebras, this definition does not depend on the choice of $i$, see Section 3.1)
2.7. Mutation of rigid modules. The results of this section are straightforward generalizations of results in [GLS5], see [GLS7, Sections 12, 13, 14] and [BIRS].

Let $A$ be a $K$-algebra, and $M$ be an $A$-module. A homomorphism $f : X \to M'$ in mod($A$) is a left add($M$)-approximation of $X$ if $M' \in \text{add}(M)$ and the induced map

$$\text{Hom}_A(f, M) : \text{Hom}_A(M', M) \to \text{Hom}_A(X, M)$$

is surjective. A morphism $f : V \to W$ is called left minimal if every morphism $g : W \to W$ with $gf = f$ is an isomorphism. Dually, one defines right add($M$)-approximations and right minimal morphisms. Some well known basic properties of approximations can be found in [GLS5, Section 3.1].

**Proposition 2.19.** Let $T$ be a basic $C_w$-maximal rigid $\Lambda$-module, and let $X$ be an indecomposable direct summand of $T$ which is not $C_w$-projective-injective. Then there are short exact sequences

$$0 \to X \overset{f'}{\to} T' \overset{g'}{\to} Y \to 0$$

and

$$0 \to Y \overset{f''}{\to} T'' \overset{g''}{\to} X \to 0$$

such that the following hold:

(i) $f'$ and $f''$ are minimal left add($T/X$)-approximations, and $g'$ and $g''$ are minimal right add($T/X$)-approximations;

(ii) $Y \oplus T/X$ is a basic $C_w$-maximal rigid $\Lambda$-module (in particular $Y$ is indecomposable), and $X \not\cong Y$;

(iii) $\dim \text{Ext}^1_A(Y, X) = \dim \text{Ext}^1_A(X, Y) = 1$;

(iv) We have $\text{add}(T') \cap \text{add}(T'') = 0$;

(v) The quiver $\Gamma_T$ of $\text{End}_\Lambda(T)^{\text{op}}$ has no loops and no 2-cycles;

(vi) We have

$$\text{gl. dim}(\text{End}_\Lambda(T)^{\text{op}}) = \begin{cases} 3 & C_w \neq \text{add}(I_w), \\ 1 & C_w = \text{add}(I_w) \text{ and } n > 1, \\ 0 & C_w = \text{add}(I_w) \text{ and } n = 1. \end{cases}$$

In the situation of the above proposition, we call $\{X, Y\}$ an exchange pair associated to $T/X$, and we write

$$\mu_X(T) = Y \oplus T/X.$$ 

We say that $Y \oplus T/X$ is the mutation of $T$ in direction $X$. The short exact sequence

$$0 \to X \overset{f'}{\to} T' \overset{g'}{\to} Y \to 0$$

is the exchange sequence starting in $X$ and ending in $Y$. Thus, we have

$$\mu_Y(\mu_X(T)) = T.$$ 

Let $T = T_1 \oplus \cdots \oplus T_r$ be a basic $C_w$-maximal rigid $\Lambda$-module with $T_k$ indecomposable for all $k$. Without loss of generality we assume that $T_{r-n+1}, \ldots, T_r$ are $C_w$-projective-injective. As in Section 2.6, write $B(T) := B(\Gamma_T) = (t_{ij})_{1 \leq i, j \leq r}$, and let $B(T)^{\circ} = (t_{ij})$ be the $r \times (r - n)$-matrix obtained from $B(T)$ by deleting the last $n$ columns.

For $1 \leq k \leq r - n$ let

$$0 \to T_k \to T' \to T_k^* \to 0$$

and

$$0 \to T_k^* \to T'' \to T_k \to 0$$
be exchange sequences associated to the direct summand $T_k$ of $T$. It follows that
\[ T' = \bigoplus_{t_{ik} < 0} T_i^{-t_{ik}} \quad \text{and} \quad T'' = \bigoplus_{t_{ik} > 0} T_i^{t_{ik}}. \]

Set
\[ T_* = \mu_{T_k}(T) = T_k^* \oplus T / T_k. \]

The quivers of the endomorphism algebras $\text{End}_\Lambda(T)^{\text{op}}$ and $\text{End}_\Lambda(\mu_{T_k}(T))^{\text{op}}$ are related via Fomin and Zelevinsky’s mutation rule:

**Theorem 2.20.** Let $w$ be a Weyl group element. For a basic $C_w$-maximal rigid $\Lambda$-module $T$ as above and $1 \leq k \leq r - n$ we have
\[ B(\mu_{T_k}(T))^\circ = \mu_k(B(T)^\circ). \]

2.8. **Categorification.** An (additive) categorification of a cluster algebra $A(\tilde{B})$ as in section 2.6 is given by the following:

(A) A $C$-linear, Hom-finite Frobenius category $\mathcal{E}$ with a cluster structure in the sense of [BIRS] II.1 on the basic $\mathcal{E}$-maximal rigid objects.

(B) A basic $\mathcal{E}$-maximal rigid object $T$ such that $B(\Gamma_T)^\circ = \tilde{B}$.

(C) A cluster character $\chi_T : \text{obj}(\mathcal{E}) \to \mathbb{C}(y_1, \ldots, y_r)$ in the sense of Palu [Pa, Definition 1.2], with triangles replaced by short exact sequences.

(D) The cluster character $\chi_T$ induces a bijection between basic, $T$-reachable $\mathcal{E}$-maximal rigid objects and clusters in $A(\tilde{B})$.

**Remark 2.21.** (1) Conditions (A)-(C) imply obviously that each cluster monomial in $A(\tilde{B})$ is of the form $\chi_R$ for some $\mathcal{E}$-rigid object $R$. Thus condition (D) is a kind of injectivity requirement for $\chi_T$.

(2) By the results in Section 2.7 we have a cluster structure on $C_w$. We can take $T = V_i$, for which we know $\Gamma_{V_i}$ by Theorem 2.10. By Theorems 2.6 and 2.7 our $\delta_T$ is a good candidate for a cluster character. In fact, by Theorems 3.1 and 3.2 below, we know that $\delta_X \in A(B(\Gamma_{V_i})^\circ)$ for all $X \in C_w$. (By Theorem 3.1 the algebra $A(B(\Gamma_{V_i})^\circ)$ is up to isomorphism a subalgebra of $\mathcal{M}^\ast$.) Property (D) holds in our situation because of the construction of the dual semicanonical basis. For this reason we call $(C_w, V_i)$ a categorification of $A(B(\Gamma_{V_i})^\circ)$.

3. Main results

In this section, let $K = \mathbb{C}$ be the field of complex numbers.

3.1. **The cluster algebra $A(C_w)$ as a subalgebra of $\mathcal{M}^\ast$.** For a reduced expression $i = (i_r, \ldots, i_1)$ of a Weyl group element $w$ let $\mathcal{T}(C_w)$ be the graph with vertices the isomorphism classes of basic $C_w$-maximal rigid $\Lambda$-modules and with edges given by mutations. Let $T = T_1 \oplus \cdots \oplus T_r$ be a vertex of $\mathcal{T}(C_w)$, and let $\mathcal{T}(C_w, T)$ denote the connected component of $\mathcal{T}(C_w)$ containing $T$. Two modules in $\mathcal{T}(C_w)$ are mutation equivalent if they belong to the same connected component. A $\Lambda$-module $X$ is called $T$-reachable if $X \in \text{add}(R)$ for some vertex $R$ of $\mathcal{T}(C_w, T)$. Denote by $\mathcal{R}(C_w, T)$ the subalgebra of $\mathcal{M}^\ast$ generated by the $\delta_{R_i}$ $(1 \leq i \leq r)$ where $R = R_1 \oplus \cdots \oplus R_r$ runs over all vertices of $\mathcal{T}(C_w, T)$. The following theorem is our first main result. The proof is given in Section 15.3.

**Theorem 3.1.** Let $w$ be a Weyl group element. Then the following hold:
(i) There is a unique isomorphism \( \iota : \mathcal{A}(C_w, T) \to \mathcal{R}(C_w, T) \) such that
\[
\iota(y_i) = \delta_{T_i} \quad (1 \leq i \leq r);
\]
(ii) If we identify the two algebras \( \mathcal{A}(C_w, T) \) and \( \mathcal{R}(C_w, T) \) via \( \iota \), then the clusters of
\( \mathcal{A}(C_w, T) \) are identified with the \( r \)-tuples \( \delta(R) = (\delta_{R_1}, \ldots, \delta_{R_r}) \), where \( R \) runs over the
vertices of the graph \( T(C_w, T) \). In particular, \( \{ \delta_X \mid X \text{ is } T \text{-reachable} \} \) is
the set of cluster monomials in \( \mathcal{R}(C_w, T) \), and all cluster monomials belong to the dual
semicanonical basis \( \mathcal{S}^* \) of \( \mathcal{M}^* \equiv U(n)_gr^* \).

The proof of Theorem 3.1 relies on Theorem 2.1.20 and the multiplication formula in
Theorem 2.7.

Write \( \mathcal{R}(C_w) := \mathcal{R}(C_w, V_1) \). (The algebra \( \mathcal{R}(C_w) \) and its cluster algebra structure do not
depend on \( i \), since all \( C_w \)- maximal rigid modules of the form \( V_i \) are mutation equivalent,
see [BIRS, Proposition III.4.3].) Theorem 3.1 shows that the cluster algebra \( \mathcal{A}(C_w) \) is
canonical isomorphic to the subalgebra \( \mathcal{R}(C_w) \) of \( U(n)_gr^* \).

As an application, our theory provides an algorithm which computes the Euler charac-
teristics \( \chi_i(F_{k, R}) \) for all cluster monomials \( \delta_R \) in \( \mathcal{R}(C_w) \) and all composition series types
\( k = (k_1, \ldots, k_s) \), see Section 13.2. This is quite remarkable, since starting from the defini-
tions this seems to be an impossible task in almost all cases.

3.2. Dual PBW-bases and dual semicanonical bases. Let \( i = (i_r, \ldots, i_1) \) be a re-
duced expression of a Weyl group element \( w \). Let \( V_i = V_1 \oplus \cdots \oplus V_r \) be defined as before.
For each \( 1 \leq k \leq r \) there is a canonical embedding
\[
\iota_k : V_{k-} \to V_k.
\]
Here we set \( V_0 := 0 \). Let \( M_k \) be the cokernel of \( \iota_k \), and define
\[
M_i := M_1 \oplus \cdots \oplus M_r.
\]
These modules play an important role in our theory. (In case \( w \) is adaptable and \( i \) is
\( Q^{op} \)-adapted, the module \( M_i \) is a terminal \( KQ \)-module in the sense of [GLS7].)

In the spirit of Ringel’s construction of PBW-bases for quantum groups [Bi4], we con-
struct dual PBW-bases for our cluster algebras \( \mathcal{A}(C_w) \). The following theorem is our
second main result. The proof will be given in Section 15.

**Theorem 3.2.** Let \( i = (i_r, \ldots, i_1) \) be a reduced expression of a Weyl group element \( w \),
and let \( M_i = M_1 \oplus \cdots \oplus M_r \) be defined as above.

(i) The cluster algebra \( \mathcal{R}(C_w) \) is a polynomial ring in \( r \) variables. More precisely, we have
\[
\mathcal{R}(C_w) = \mathbb{C}[\delta_{M_1}, \ldots, \delta_{M_r}] = \text{Span}_{\mathbb{C}}(\delta_X \mid X \in \mathcal{C}_w);
\]
(ii) The set \( \{ \delta_M \mid M \in \text{add}(M_i) \} \) is a \( \mathbb{C} \)-basis of \( \mathcal{R}(C_w) \);
(iii) The subset \( \mathcal{S}^*_w := \mathcal{S}^* \cap \mathcal{R}(C_w) \) of the dual semicanonical basis is a \( \mathbb{C} \)-basis of \( \mathcal{R}(C_w) \)
containing all cluster monomials.

Let \( \widetilde{\mathcal{R}}(C_w) \) be the algebra obtained from \( \mathcal{R}(C_w) \) by formally inverting the elements \( \delta_P \)
for all \( C_w \)-projective-injectives \( P \). In other words, \( \mathcal{R}(C_w) \) is the cluster algebra obtained
from \( \mathcal{R}(C_w) \) by inverting the generators of its coefficient ring. Similarly, let \( \mathcal{R}(C_w) \) be
the cluster algebra obtained from \( \mathcal{R}(C_w) \) by specializing the elements \( \delta_P \) to 1. For both
cluster algebras \( \mathcal{R}(C_w) \) and \( \mathcal{R}(C_w) \) we get a \( \mathbb{C} \)-basis which is easily obtained from the dual
semicanonical basis \( \mathcal{S}^*_w \) and again contains all cluster monomials, see Sections 15.5 and
15.6.
3.3. The shift functor in $C_w$. As mentioned before, the category $C_w$ is a triangulated category with shift functor $\Omega_w^{-1}$. Recall that $V_1 = V_1 \oplus \cdots \oplus V_r$ is a basic $C_w$-maximal rigid module. Set $T_1 := I_w \oplus \Omega_w^{-1}(V_1)$. In Section 13.3 we construct a sequence of mutations which starts in $V_1$ and ends in $T_1$. This mutation sequence is crucial for the proof of some of our results. (For example, it helps to show that the coordinate rings $\mathbb{C}[N(w)]$ and $\mathbb{C}[N^w]$ are generated by the set of cluster variables.)

Now let $R = R_1 \oplus \cdots \oplus R_r$ be any $C_w$-maximal rigid $\Lambda$-module, which is mutation equivalent to $V_1$. Suppose that we know a sequence of mutations starting in $V_1$ and ending in $R$. Then we can use the mutation sequence from $V_1$ to $T_1$ to obtain a mutation sequence between $R$ and $I_w \oplus \Omega_w^{-1}(R)$, and between $R$ and $I_w \oplus \Omega_w(R)$, see Section 13.3.

3.4. Unipotent subgroups and cells. Let $w$ be a Weyl group element and put $\Delta^+_w := \{\alpha \in \Delta^+ | w(\alpha) < 0\}$. Let

$$n(w) = \bigoplus_{\alpha \in \Delta^+_w} n_{\alpha}$$

be the corresponding sum of root subspaces of $n$, see Section 4.3. This is a finite-dimensional nilpotent Lie algebra. Let $N(w)$ be the corresponding finite-dimensional unipotent group, see Section 5.2.

The maximal Kac-Moody group attached to $g$ as in [Ku, Chapter 6] comes with a pair of subgroups $N$ and $N_-$ (denoted by $U$ and $U_-$ in [Ku]). Note that later on for the definition of generalized minors in Section 7 we also have to work with the minimal Kac-Moody group (denoted by $G^\text{min}$ in in [Ku, 7.4]). We have

$$N(w) = N \cap (w^{-1}N_-w).$$

We also define the unipotent cell

$$N^w := N \cap (B_-wB_-)$$

where $B_-$ is the standard negative Borel subgroup of the Kac-Moody group.

Every $\Lambda$-module $X$ in $C_w$ gives rise to a linear form $\delta_X \in \mathcal{M}^* \equiv U(n)^{gr*}$ and by means of the identification $U(n)^{gr*} \equiv \mathbb{C}[N]$ to a regular function $\varphi_X$ on $N$.

The following theorem, proved in Section 8 is our third main result.

**Theorem 3.3.** The algebras $\mathbb{C}[N(w)]$ and $\mathbb{C}[N^w]$ of regular functions on $N(w)$ and $N^w$, respectively, have a cluster algebra structure. For each reduced expression $i = (i_r, \ldots, i_1)$ of $w$, the tuple $((\varphi_{V_{i_1}, \ldots}, \varphi_{V_{i_r}}), B(\Gamma_{V_{i_1}}))$ provides an initial seed of these cluster algebra structures. The functions $\varphi_{V_{i_k}} \in \mathbb{C}[N]$ can be interpreted as generalized minors. We obtain natural cluster algebra isomorphisms

$$\mathbb{C}[N(w)] \cong \mathcal{R}(C_w) \quad \text{and} \quad \mathbb{C}[N^w] \cong \mathcal{R}(C_w).$$

As a result, we have obtained a categorification in the sense of [2.8] of the cluster algebra structure on $\mathbb{C}[N(w)]$ and $\mathbb{C}[N^w]$.

3.5. Example. We are going to illustrate some of the previous results on an example. Let $Q$ be a quiver with underlying graph $1 \rightarrow 2 \rightarrow 3 \rightarrow 4$ and let $i := (3, 4, 2, 1, 3, 4, 2, 1)$. This is a reduced expression of the Weyl group element $w := s_3s_4s_3s_1s_3s_4s_2s_1$. The category $C_w$ contains 18 indecomposable modules, and 4 of these are $C_w$-projective-injective. The stable category $\underline{C}_w$ is triangle equivalent to the cluster category $\mathcal{C}_Q$. 

The maximal rigid module \( V_1 \) has 8 indecomposable direct summands, namely

\[
V_1 = 1, \quad V_2 = \begin{pmatrix} 1 & 0 \\ 0 & 2 \end{pmatrix}, \quad V_3 = 4, \quad V_4 = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \end{pmatrix}, \\
V_5 = I_{1,1} = \begin{pmatrix} 2 & 0 \\ 0 & 1 \end{pmatrix}, \quad V_6 = I_{1,2} = \begin{pmatrix} 2 & 3 & 4 \\ 5 & 6 & 7 \end{pmatrix}, \quad V_7 = I_{1,4} = \begin{pmatrix} 2 & 3 & 4 \\ 5 & 6 & 7 \end{pmatrix}, \quad V_8 = I_{1,3} = \begin{pmatrix} 2 & 3 & 4 \\ 5 & 6 & 7 \end{pmatrix}.
\]

Similarly, \( T_1 \) has 4 non-\( \mathcal{O}_w \)-projective-injective indecomposable direct summands, namely

\[
T_1 = 2, \quad T_2 = \begin{pmatrix} 2 & 3 & 4 \\ 5 & 6 & 7 \end{pmatrix}, \quad T_3 = \begin{pmatrix} 2 & 3 \\ 4 & 5 \end{pmatrix}, \quad T_4 = \begin{pmatrix} 2 & 3 \\ 4 & 5 \end{pmatrix}.
\]

Here we set \( T_k := \Omega_w^{-1}(V_k) \) for \( 1 \leq k \leq 4 \).

The group \( N \) can be taken to be the group of upper unitriangular \( 5 \times 5 \) matrices with complex coefficients. Given two subsets \( I \) and \( J \) of \( \{1, 2, \ldots, 5\} \) with \( |I| = |J| \), we denote by \( D_{I,J} \in \mathbb{C}[N] \) the regular function mapping an element \( x \in N \) to its minor \( D_{I,J}(x) \) with row subset \( I \) and column subset \( J \). We get

\[
\varphi_{V_1} = D_{\{1\},\{2\}}, \quad \varphi_{V_2} = D_{\{1\},\{23\}}, \quad \varphi_{V_3} = D_{\{1\},\{234\}}, \quad \varphi_{V_4} = D_{\{1\},\{2345\}}, \\
\varphi_{V_5} = D_{\{1\},\{3\}}, \quad \varphi_{V_6} = D_{\{1\},\{35\}}, \quad \varphi_{V_7} = D_{\{1\},\{345\}}, \quad \varphi_{V_8} = D_{\{1\},\{34\}}, \\
\varphi_{T_1} = D_{\{1\},\{13\}}, \quad \varphi_{T_2} = D_{\{1\},\{135\}}, \quad \varphi_{T_3} = D_{\{1\},\{123\}}, \quad \varphi_{T_4} = D_{\{1\},\{1234\}}.
\]

The unipotent subgroup \( N^w \) is a locally closed subset of \( N \) defined by the following equations and inequalities:

\[
N^w = \{ x \in N \mid D_{\{1\},\{4\}}(x) = D_{\{1\},\{5\}}(x) = D_{\{1\},\{45\}}(x) = 0, \; D_{\{1\},\{3\}}(x) \neq 0, \; D_{\{1\},\{35\}}(x) \neq 0, \; D_{\{1\},\{345\}}(x) \neq 0, \; D_{\{1\},\{123\}}(x) \neq 0, \; D_{\{1\},\{1234\}}(x) \neq 0 \}.
\]

Note that the 4 inequalities are given by the non-vanishing of the 4 regular functions \( \varphi_{I_{1,j}} \), \( 1 \leq j \leq 4 \) attached to the indecomposable \( \mathcal{O}_w \)-projective-injective modules. We have

\[
D_{\{1\},\{4\}} = \varphi_{\begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}}, \quad D_{\{1\},\{5\}} = \varphi_{\begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}}, \quad D_{\{1\},\{45\}} = \varphi_{\begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}}.
\]

Our results show that the polynomial algebra \( \mathbb{C}[N(w)] \) has a cluster algebra structure, of which \( (\varphi_{V_1}, \varphi_{V_2}, \varphi_{V_3}, \varphi_{V_4}, \varphi_{I_{1,1}}, \varphi_{I_{1,2}}, \varphi_{I_{1,3}}, \varphi_{I_{1,4}}) \) is a distinguished cluster. Its coefficient ring is the polynomial ring in the four variables \( (\varphi_{I_{1,1}}, \varphi_{I_{1,2}}, \varphi_{I_{1,3}}, \varphi_{I_{1,4}}) \). The cluster mutations of this algebra come from mutations of the basic \( \mathcal{O}_w \)-maximal rigid \( \Lambda \)-modules. Moreover, if we replace the coefficient ring by the ring of Laurent polynomials in the four variables \( (\varphi_{I_{1,1}}, \varphi_{I_{1,2}}, \varphi_{I_{1,3}}, \varphi_{I_{1,4}}) \), we obtain the coordinate ring \( \mathbb{C}[N^w] \).

4. Kac-Moody Lie algebras

From now on, let \( K = \mathbb{C} \) be the field of complex numbers. In this section we recall known results on Kac-Moody Lie algebras.
4.1. Kac-Moody Lie algebras. Let $\Gamma = (\Gamma_0, \Gamma_1, \gamma)$ be a finite graph (without loops). It has as set of vertices $\Gamma_0$, edges $\Gamma_1$ and $\gamma: \Gamma_1 \to P_2(\Gamma_0)$ determining the adjacency of the edges; here $P_2(\Gamma_0)$ denotes the set of two-element subsets of $\Gamma_0$. If $\Gamma_0 = \{1, 2, \ldots, n\}$ we can assign to $\Gamma$ a symmetric generalized Cartan matrix $C_\Gamma = (c_{ij})_{1 \leq i, j \leq n}$, which is an $n \times n$-matrix with integer entries

$$c_{ij} := \begin{cases} 2 & \text{if } i = j, \\ \gamma^{-1}(|\{i, j\}|) & \text{if } i \neq j. \end{cases}$$

Obviously, the assignment $\Gamma \mapsto C_\Gamma$ induces a bijection between isomorphism classes of graphs with vertex set $\{1, 2, \ldots, n\}$ and symmetric generalized Cartan matrices in $\mathbb{Z}^{n \times n}$ up to simultaneous permutation of rows and columns.

For a quiver $Q = (Q_0, Q_1, s, t)$ as defined in Section 2.1 its underlying graph $|Q| := (Q_0, q)$ is given by $q(a) = \{s(a), t(a)\}$ for all $a \in Q_1$ i.e. it is obtained by “forgetting” the orientation of the edges. We write $C_Q := C_{|Q|} := (c_{ij})_{i,j}.

Let $g := g_Q := g(C_Q)$ be the (symmetric) Kac-Moody Lie algebra (see [Ka]) associated to $Q$, which is defined as follows: Let $h$ be a $\mathbb{C}$-vector space of dimension $2n - \text{rank}(C_Q)$, and let $\Pi := \{\alpha_1, \ldots, \alpha_n\} \subset h^*$ and $\Pi^\vee := \{\alpha_1^\vee, \ldots, \alpha_n^\vee\} \subset h$ be linearly independent subsets of the vector spaces $h^*$ and $h$, respectively, such that

$$\alpha_i(\alpha_j^\vee) = c_{ij}$$

for all $i, j$.

Let $h^* = h_1^* \oplus h_2^*$ be a vector space decomposition, where $h_1^*$ is just the subspace with basis $\Pi$, and $h_2^*$ is any direct complement of $h_1^*$ in $h^*$. Let $(-, -): h^* \times h^* \to \mathbb{C}$ be the standard bilinear form, defined by $(\alpha_j, \alpha_j) := \alpha_i(\alpha_j^\vee)$, $(\alpha_i, x) := (x, \alpha_i) := x(\alpha_i^\vee)$, and $(x, y) := 0$ for all $x, y \in h_2^*$ and $1 \leq i, j \leq n$. Note that $\alpha_i(\alpha_j^\vee) = (\dim(S_i), \dim(S_j))_Q$, where $(-, -)_Q$ is the bilinear form defined in Section 2.1.

Now $g = (g, [-, -])$ is the Lie algebra over $\mathbb{C}$ generated by $h$ and the symbols $e_i$ and $f_i$ ($1 \leq i \leq n$) satisfying the following defining relations:

(L1) $[h, h'] = 0$ for all $h, h' \in h$,

(L2) $[h, e_i] = \alpha_i(h)e_i$, and $[h, f_i] = -\alpha_i(h)f_i$,

(L3) $[e_i, f_i] = \alpha_i^\vee$ and $[e_i, f_j] = 0$ for all $i \neq j$,

(L4) $\text{ad}(e_j)^{1-c_{ij}}(e_j) = 0$ for all $i \neq j$,

(L5) $\text{ad}(f_j)^{1-c_{ij}}(f_j) = 0$ for all $i \neq j$.

(For $x, y \in g$ and $m \geq 1$ we set $\text{ad}(x)(y) := \text{ad}(x)(y) := [x, y]$ and $\text{ad}(x)^m(y) := \text{ad}(x)^m([x, y])$.)

The Lie algebra $g$ is finite-dimensional if and only if $Q$ is a Dynkin quiver. In this case, this is the usual Serre presentation of the simple Lie algebra associated to $Q$.

Conversely, if $g = g(C)$ is a Kac-Moody Lie algebra defined by a symmetric generalized Cartan matrix $C$, we say that $g$ is of type $\Gamma$ if $C = C_\Gamma$. This is well defined for symmetric Kac-Moody Lie algebras. We call $\Gamma$ the Dynkin graph of $g$.

For $\alpha \in h^*$ let

$$g_\alpha := \{x \in g \mid [h, x] = \alpha(h)x \text{ for all } h \in h\}.$$ 

One can show that $\dim g_\alpha < \infty$ for all $\alpha$. By

$$R := \sum_{i=1}^{n} \mathbb{Z} \alpha_i$$
we denote the root lattice of $\mathfrak{g}$. Define $R^+ := \mathbb{N}\alpha_1 \oplus \cdots \oplus \mathbb{N}\alpha_n$. The roots of $\mathfrak{g}$ are defined as the elements in

$$\Delta := \{ \alpha \in R \setminus \{0\} \mid \mathfrak{g}_\alpha \neq 0 \}.$$  

Set $\Delta^+ := \Delta \cap R^+$ and $\Delta^- := \Delta \cap (-R^+)$. One can show that $\Delta = \Delta^+ \cup \Delta^-$. The elements in $\Delta^+$ and $\Delta^-$ are the positive roots and the negative roots, respectively. The elements in $\{\alpha_1, \ldots, \alpha_n\}$ are positive roots of $\mathfrak{g}$ and are called simple roots.

One has the triangular decomposition $\mathfrak{g} = \mathfrak{n}_- \oplus \mathfrak{h} \oplus \mathfrak{n}$ with

$$\mathfrak{n}_- = \bigoplus_{\alpha \in \Delta^+} \mathfrak{g}_\alpha \quad \text{and} \quad \mathfrak{n} = \bigoplus_{\alpha \in \Delta^+} \mathfrak{g}_\alpha.$$  

The Lie algebra $\mathfrak{n}$ is generated by $e_1, \ldots, e_n$ with defining relations (L4). Set $\mathfrak{n}_\alpha := \mathfrak{g}_\alpha$ if $\alpha \in R^+ \setminus \{0\}$.

For $1 \leq i \leq n$ define an element $s_i$ in the automorphism group $\text{Aut}(\mathfrak{h}^*)$ of $\mathfrak{h}^*$ by

$$s_i(\alpha) := \alpha - \alpha(\alpha_i^\vee)\alpha_i$$

for all $\alpha \in \mathfrak{h}^*$. The subgroup $W \subset \text{Aut}(\mathfrak{h}^*)$ generated by $s_1, \ldots, s_n$ is the Weyl group of $\mathfrak{g}$. The elements $s_i$ are called Coxeter generators of $W$. The identity element of $W$ is denoted by $1$. The length $l(w)$ of some $w \neq 1$ in $W$ is the smallest number $t \geq 1$ such that $w = s_{i_1} \cdots s_{i_t} s_{i_1}$ for some $1 \leq i_j \leq n$. In this case $(i_t, \ldots, i_2, i_1)$ is a reduced expression for $w$. Let $R(w)$ be the set of all reduced expressions for $w$. We set $l(1) = 0$.

A root $\alpha \in \Delta$ is a real root if $\alpha = w(\alpha_i)$ for some $w \in W$ and some $i$. It is well known that $\dim \mathfrak{g}_\alpha = 1$ if $\alpha$ is a real root. By $\Delta_{\text{re}}$ we denote the set of real roots of $\mathfrak{g}$. Define $\Delta_{\text{re}}^+ := \Delta_{\text{re}} \cap \Delta^+$.

Finally, let us fix a basis $\{\varpi_j \mid 1 \leq j \leq 2n - \text{rank}(C_Q)\}$ of $\mathfrak{h}^*$ such that

$$\varpi_j(\alpha_i^\vee) = \delta_{ij}, \quad (1 \leq i \leq n, \ 1 \leq j \leq 2n - \text{rank}(C_Q)).$$

The $\varpi_j$ are the fundamental weights. We denote by

$$P := \{ \nu \in \mathfrak{h}^* \mid \nu(\alpha_i^\vee) \in \mathbb{Z} \text{ for all } 1 \leq i \leq n \}$$

the integral weight lattice, and we set

$$P^+ := \{ \nu \in P \mid \nu(\alpha_i^\vee) \geq 0 \text{ for all } 1 \leq i \leq n \}.$$  

The elements in $P^+$ are called integral dominant weights. We have

$$P = \bigoplus_{j=1}^n \mathbb{Z}\varpi_j \oplus \bigoplus_{j=n+1}^{2n-\text{rank}(C_Q)} \mathbb{C}\varpi_j \quad \text{and} \quad P^+ = \bigoplus_{j=1}^n \mathbb{N}\varpi_j \oplus \bigoplus_{j=n+1}^{2n-\text{rank}(C_Q)} \mathbb{C}\varpi_j.$$  

Define

$$\mathfrak{P} := \bigoplus_{j=1}^n \mathbb{Z}\varpi_j \quad \text{and} \quad \mathfrak{P}^+ := \bigoplus_{j=1}^n \mathbb{N}\varpi_j.$$  

The lattice $\mathfrak{P}$ can be naturally identified with the weight lattice of the derived subalgebra $\mathfrak{g}' := [\mathfrak{g}, \mathfrak{g}]$ of $\mathfrak{g}$. 

4.2. The universal enveloping algebra $U(n)$. The universal enveloping algebra $U(n)$ of the Lie algebra $n$ is the associative $\mathbb{C}$-algebra defined by generators $E_1, \ldots, E_n$ and relations

$$
\sum_{k=0}^{1-c_{ij}} (-1)^k E_i^{(k)} E_j^{(1-c_{ij} - k)} = 0
$$

for all $i \neq j$, where the $c_{ij}$ are the entries of the generalized Cartan matrix $C_Q$, and let

$$
E_i^{(k)} := E_i^k / k!.
$$

We have a canonical embedding $\iota: n \to U(n)$ which maps $e_i$ to $E_i$ for all $1 \leq i \leq n$. We consider $n$ as a subspace of $U(n)$, and we also identify $e_i$ and $E_i$.

Let

$$
J = \begin{cases} 
\mathbb{N}_1 & \text{if } \dim(n) = \infty, \\
\{1, 2, \ldots, d\} & \text{if } \dim(n) = d.
\end{cases}
$$

Let $P := \{p_i \mid i \in J\}$ be a $\mathbb{C}$-basis of $n$ such that $P \cap n_\alpha$ is a basis of $n_\alpha$ for all positive roots $\alpha$. We assume that $\{e_1, \ldots, e_n\} \subset P$. Thus $e_i$ is a basis vector of the (1-dimensional) space $n_\alpha_i$. For $k \geq 0$ define

$$
p_i^{(k)} := p_i^k / k!.
$$

Let $\mathbb{N}^{(J)}$ be the set of tuples $(m_i)_{i \in J}$ of natural numbers $m_i$ such that $m_i = 0$ for all but finitely many $m_i$. For $m = (m_i)_{i \geq 1} \in \mathbb{N}^{(J)}$ define

$$
p_m := p_1^{(m_1)} p_2^{(m_2)} \cdots p_s^{(m_s)}
$$

where $s$ is chosen such that $m_j = 0$ for all $j > s$.

**Theorem 4.1** (Poincaré-Birkhoff-Witt). The set

$$
\mathcal{P} := \left\{ p_m \mid m \in \mathbb{N}^{(J)} \right\}
$$

is a $\mathbb{C}$-basis of $U(n)$.

The basis $\mathcal{P}$ is called a PBW-basis of $U(n)$. For $d = (d_1, \ldots, d_n) \in \mathbb{N}^n$ let $U_d$ be the subspace of $U(n)$ spanned by the elements of the form $e_{i_1} e_{i_2} \cdots e_{i_m}$, where for each $1 \leq i \leq n$ the set $\{k \mid i_k = i, 1 \leq k \leq m\}$ contains exactly $d_i$ elements. It follows that

$$
U(n) = \bigoplus_{d \in \mathbb{N}^n} U_d.
$$

This turns $U(n)$ into an $\mathbb{N}^n$-graded algebra.

Furthermore, $U(n)$ is a cocommutative Hopf algebra with comultiplication

$$
\Delta: U(n) \to U(n) \otimes U(n)
$$

defined by $\Delta(x) := 1 \otimes x + x \otimes 1$ for all $x \in n$. It is easy to check that

$$
\Delta(p_m) = \sum_k p_k \otimes p_{m-k},
$$

where the sum is over all tuples $k = (k_i)_{i \geq 1}$ with $0 \leq k_i \leq m_i$ for every $i$.

By $U_d^*$ we denote the vector space dual of $U_d$. Define the graded dual of $U(n)$ by

$$
U(n)^*_\text{gr} := \bigoplus_{d \in \mathbb{N}^n} U_d^*.
$$
It follows that \( U(n)_{gr}^* \) is a commutative associative \( \mathbb{C} \)-algebra with multiplication defined via the comultiplication \( \Delta \) of \( U(n) \): For \( f', f'' \in U(n)_{gr}^* \) and \( x \in U(n) \), we have
\[
(f' \cdot f'')(x) = \sum_{(x)} f'(x(1)) f''(x(2)),
\]
where (using the Sweedler notation) we write
\[
\Delta(x) = \sum_{(x)} x(1) \otimes x(2).
\]

Let \( P := \{n \} \). The next lemma is also well known.

The set \( \Delta^+ \)

expression (\( \Delta^+ \) n variables \( p \). The Lie algebra

\[ \Theta \text{ is bracket closed, } \hat{\Theta} \text{ is bracket closed} \]

that is, each element \( p^*_m \) in \( P^* \) is equal to a monomial in the \( p^*_i \)’s. Hence, the graded dual \( U(n)_{gr}^* \) can be identified with the polynomial algebra \( \mathbb{C}[p^*_1, p^*_2, \ldots] \) (with countably many variables \( p^*_i \)).

4.3. The Lie algebra \( n(w) \). Let

\[
\hat{n} := \prod_{\alpha \in \Delta^+} n_\alpha
\]

be the completion of \( n \). A subset \( \Theta \subseteq \Delta^+ \) is bracket closed if for all \( \alpha, \beta \in \Theta \) with \( \alpha + \beta \in \Delta^+ \) we have \( \alpha + \beta \in \Theta \). In this case, we define
\[
\hat{n}(\Theta) := \prod_{\alpha \in \Theta} n_\alpha.
\]

Since \( \Theta \) is bracket closed, \( \hat{n}(\Theta) \) is a Lie subalgebra of \( \hat{n} \). One calls \( \Theta \) bracket coclosed if \( \Delta^+ \setminus \Theta \) is bracket closed.

For \( w \in W \) set \( \Delta^+_w := \{ \alpha \in \Delta^+ | w(\alpha) < 0 \} \). It is well known that for each reduced expression \( (i_r, \ldots, i_2, i_1) \in R(w) \) we have
\[
\Delta^+_w = \{ \alpha_{i_1}, s_{i_1}(\alpha_{i_2}), \ldots, s_{i_1}s_{i_2} \ldots s_{i_r-1}(\alpha_{i_r}) \}.
\]

For \( 1 \leq k \leq r \) set
\[
\beta_k(k) := \begin{cases} \alpha_{i_1} & \text{if } k = 1, \\ s_{i_1}s_{i_2} \ldots s_{i_{k-1}}(\alpha_{i_k}) & \text{otherwise}. \end{cases}
\]

The set \( \Delta^+_w \) contains \( l(w) \) positive roots, all of these are real roots, see for example [Ku, 1.3.14]. The next lemma is also well known.

Lemma 4.2. For every \( w \in W \), the set \( \Delta^+_w \) is bracket closed and bracket coclosed.

Let \( n(w) := \hat{n}(\Delta^+_w) \) be the nilpotent Lie algebra associated to \( w \). We have
\[
n(w) = \bigoplus_{\alpha \in \Delta^+_w} n_\alpha
\]

and \( \dim n(w) = l(w) \).

Again, let \( i = (i_r, \ldots, i_1) \) be a reduced expression. As in Section 4.2 we choose a \( \mathbb{C} \)-basis \( P = \{p_j \mid j \in J \} \) such that \( P \cap n_\alpha \) is a basis of \( n_\alpha \) for all positive roots \( \alpha \). The resulting
PBW-basis $\mathcal{P} = \{p_m \mid m \in \mathbb{N}^{(I)}\}$ of $U(\mathfrak{n})$ is called $i$-compatible provided the vector $p_k$ belongs to $\mathfrak{n}_{h(k)}$ for all $1 \leq k \leq r$. In this case

$$\mathcal{P}_i := \{p_{(m_1)}^1 p_{(m_2)}^2 \cdots p_{(m_r)}^r \mid m_k \geq 0 \text{ for all } 1 \leq k \leq r\}$$

is a PBW-basis of the universal enveloping algebra $U(\mathfrak{n}(w))$ of $\mathfrak{n}(w)$, and

$$\mathcal{P}^*_i := \{(p_{(m_1)}^1)^{m_1} (p_{(m_2)}^2)^{m_2} \cdots (p_{(m_r)}^r)^{m_r} \mid m_k \geq 0 \text{ for all } 1 \leq k \leq r\}$$

is the corresponding dual PBW-basis of the graded dual $U(\mathfrak{n}(w))^*_{gr}$.

4.4. **Highest weight modules.** A $U(\mathfrak{g})$-module $M$ is a weight module or $\mathfrak{h}$-diagonalizable if

$$M = \bigoplus_{\mu \in \mathfrak{h}^*} M_\mu$$

where

$$M_\mu := \{m \in M \mid h \cdot m = \mu(h)m \text{ for all } h \in \mathfrak{h}\}.$$

For each vector $v \in M_\mu$ let $\text{wt}(v) := \mu$ be its weight. Analogously, one defines when a right $U(\mathfrak{g})$-module is a weight module.

A $U(\mathfrak{g})$-module $M$ is a highest weight module if the following hold:

- $M$ is a weight module;
- There is a vector $v \in M$ with $U(\mathfrak{g}) \cdot v = M$;
- $e_i \cdot v = 0$ for all $i$.

A right $U(\mathfrak{g})$-module $M$ is a lowest weight module if the following hold:

- $M$ is a weight module;
- There is a vector $u \in M$ with $u \cdot U(\mathfrak{g}) = M$;
- $u \cdot f_i = 0$ for all $i$.

When we work with right $U(\mathfrak{g})$-modules, we invert the usual ordering on weights. So if $M$ is a lowest weight right $U(\mathfrak{g})$-module, then the vector $u$ (which is uniquely determined up to a non-zero scalar) has actually the lowest weight of $M$. Indeed, if $m \in M_\mu$ and $h \in \mathfrak{h}$, then we have

$$(m \cdot e_i) \cdot h = (\mu(h)m) \cdot e_i - (\alpha_i(h)m) \cdot e_i = (\mu - \alpha_i(h))(m \cdot e_i).$$

Here we used that $[h, e_i] = he_i - e_i h = \alpha_i(h)e_i$. So $m \cdot e_i$ has weight $\mu - \alpha_i$.

4.5. **Construction of highest weight modules.** In this section we present some of our results from [GLS3] in a form convenient for our present purpose. For $\nu \in P^+$ we write

$$\hat{I}_\nu := \bigoplus_{i=1}^{n} \hat{I}_i^{\nu(\alpha_i^\vee)}.$$

For $1 \leq i \leq n$ and a nilpotent $\Lambda$-module $X$ we denote by $\mathcal{G}(i, X)$ the variety of submodules $Y$ of $X$ such that $X/Y \cong S_i$. Similarly, if

$$\text{soc}(X) = \bigoplus_{i=1}^{n} S_i^{m_i}$$

and $\nu \in P^+$ is such that $\nu(\alpha^\vee_i) \geq m_i$ for $1 \leq i \leq n$, then we have an embedding $X \hookrightarrow \hat{I}_\nu$. In this case, we denote by $\mathcal{G}(i, \nu, X)$ the variety of submodules $Y$ of $\hat{I}_\nu$ such that $X \subset Y$ and $Y/X \cong S_i$. Hence, if $\dim(X) = \beta$ and $f \in M_{\beta - \alpha_i}$, we can form the following sum

$$
\Sigma := \sum_{m \in C} m \chi_c(\{Y \in \mathcal{G}(i, X) \mid f(Y) = m\}).
$$

For convenience we shall denote such an expression by an integral, for example,

$$
\Sigma = \int_{Y \in \mathcal{G}(i, X)} f(Y).
$$

Similarly, there exists a partition

$$
\mathcal{G}(i, X) = \bigsqcup_{j=1}^m A_j
$$

into constructible subsets such that $\delta_Y = \delta_{Y'}$ for all $Y, Y' \in A_j$. Then, choosing arbitrary $Y_j \in A_j$ for $j = 1, \ldots, m$, we can also denote by an integral the following element of $M^*_{\beta - \alpha_i}$

$$
\int_{Y \in \mathcal{G}(i, X)} \delta_Y = \sum_{j=1}^m \chi_c(A_j) \delta_{Y_j}.
$$

**Theorem 4.3.** Let $\lambda \in P$ be an integral weight, and let $M_{\text{low}}(\lambda)$ be the lowest weight Verma right $U(\mathfrak{g})$-module (with underlying vector space $U(\mathfrak{n})$) with lowest weight $\lambda$. Under the identifications

$$
M_{\text{low}}(\lambda) \equiv U(\mathfrak{n}) \equiv M
$$

the corresponding right $U(\mathfrak{g})$-module structure on $M$ is described as follows: The generators $e_i \in \mathfrak{n}$, $f_i \in \mathfrak{n}_-$, $h \in \mathfrak{h}$ act on $g \in M_\beta$ by

$$
(g \cdot e_i)(X') = \int_{Y \in \mathcal{G}(i, X')} g(Y),
$$

$$
(g \cdot f_i)(X) = \int_{Y \in \mathcal{G}(i, \nu, X)} g(Y) - (\nu - \lambda)(\alpha^\vee_i)g(X \oplus S_i),
$$

$$
g \cdot h = (\lambda - \beta)(h)g,
$$

where $X' \in \Lambda_{\beta + \alpha_i}$, $X \in \Lambda_{\beta - \alpha_i}$ and $\nu \in P^+$ are as above.

Note that $g \cdot e_i = g \ast 1_i$ by our convention for the multiplication in $M$. Moreover, the formula for $g \cdot f_i \in M_{\beta - \alpha_i}$ is in fact independent of the choice of $\nu$.

For each $\mathfrak{h}$-diagonalizable right $U(\mathfrak{g})$-module

$$
M = \bigoplus_{\mu \in \mathfrak{h}^*} M_\mu
$$

one can consider the dual representation

$$
M^* = \bigoplus_{\mu \in \mathfrak{h}^*} M^*_\mu
$$

defined by $M^*_\mu := \text{Hom}_\mathbb{C}(M_\mu, \mathbb{C})$. It acquires the structure of a left $U(\mathfrak{g})$-module via

$$
(x \cdot \phi)(m) := \phi(m \cdot x), \quad (x \in U(\mathfrak{g}), \ m \in M).
$$
Consider the canonical epimorphism from the Verma module \( M_{\text{low}}(\lambda) \) to the irreducible lowest weight right \( U(\mathfrak{g}) \)-module \( L_{\text{low}}(\lambda) \). For the corresponding dual representations we obtain an inclusion
\[
L^*_{\text{low}}(\lambda) \hookrightarrow M^*_{\text{low}}(\lambda).
\]
It is well known that \( L^*_{\text{low}}(\lambda) \) is isomorphic to the irreducible highest weight left \( U(\mathfrak{g}) \)-module \( L(\lambda) \) with highest weight \( \lambda \). This yields the following realization of the integrable module \( L(\lambda) \) in terms of \( \delta \)-functions.

**Theorem 4.4.** Let \( \lambda \in P^+ \) be an integral dominant weight. The subspace
\[
U(\lambda) := \operatorname{Span}_C \langle \delta_X \mid X \text{ submodule of } \hat{I}_\lambda \rangle
\]
of \( U(\mathfrak{n})^*_{\text{gr}} \) carries the above-mentioned structure of an irreducible highest weight left \( U(\mathfrak{g}) \)-module \( L(\lambda) \). For such \( X \) with \( \dim(X) = \beta \) the action of the Chevalley generators of \( U(\mathfrak{g}) \) is given by
\[
\begin{align*}
e_i \cdot \delta_X &= \int_{Y \in G'(i,X)} \delta_Y, \\
f_i \cdot \delta_X &= \int_{Y' \in G'(i,\lambda,X)} \delta_{Y'}, \\
h \cdot \delta_X &= (\lambda - \beta)(h)\delta_X.
\end{align*}
\]

Note that \( U(\mathfrak{n})^*_{\text{gr}} \) carries also a right \( U(\mathfrak{g}) \)-module structure coming from the left regular representation of \( U(\mathfrak{n}) \). In order to describe it, we introduce the following definition. For \( X \in \Lambda_\beta \) we denote by \( G'(i,X) \) the variety of submodules \( Y \) of \( X \) such that \( \dim(Y) = \alpha_i \). Each element of this space is isomorphic to \( S_i \) and clearly \( G'(i,X) \) is a projective space. It is easy to see that
\[
\delta_X \cdot e_i = \int_{S \in G'(i,X)} \delta_{X/S}.
\]
Under the above identification \( M^*_{\text{low}}(\lambda) \equiv U(\mathfrak{n})^*_{\text{gr}} \), the subspace of \( U(\mathfrak{n})^*_{\text{gr}} \) carrying the \( U(\mathfrak{g}) \)-module \( L(\lambda) \) can be described as follows.

**Corollary 4.5.** For \( \lambda \in P^+ \) we have
\[
U(\lambda) = \left\{ \phi \in U(\mathfrak{n})^*_{\text{gr}} \mid \phi \cdot e_i^{\lambda(\alpha_i^\vee)} + 1 = 0 \text{ for all } 1 \leq i \leq n \right\}.
\]

*Proof.* The nilpotent \( \Lambda \)-module \( X \) is isomorphic to a submodule of \( \hat{I}_\lambda \) if and only if
\[
\delta_X \cdot e_i^{\lambda(\alpha_i^\vee)} + 1 = 0
\]
for every \( i \). The claim then follows from Theorem 4.4. \( \square \)

Note that for \( \lambda, \mu \in P^+ \) we have \( U(\lambda) = U(\mu) \) if and only if
\[
\lambda - \mu \in \bigoplus_{j=n+1}^{2n-\operatorname{rank}(C_Q)} \mathbb{C} \omega_j.
\]
5. Unipotent groups

5.1. The group \( N \) and its coordinate ring \( \mathbb{C}[N] \). The completion \( \hat{n} \) of \( n \) defined in \[4.3\] is a pro-nilpotent pro-Lie algebra, see [Ku, Section 6.1.1]. Let \( N \) be the pro-unipotent pro-group with Lie algebra \( \hat{n} \). We refer to Kumar’s book [Ku, Section 4.4] for all missing definitions.

We can assume that \( N = \hat{n} \) as a set and that the multiplication of \( N \) is defined via the Baker-Campbell-Hausdorff formula. Hence the exponential map \( \text{Exp}: \hat{n} \to N \) is just the identity map.

Put \( H := U(n)_g^* \). This is a commutative Hopf algebra. We can regard \( H \) as the coordinate ring \( \mathbb{C}[N] \) of \( N \), that is, we can identify \( N \) with the set \( \text{maxSpec}(H) \equiv \text{Hom}_{\text{alg}}(H, \mathbb{C}) \) of \( \mathbb{C} \)-algebra homomorphisms \( H \to \mathbb{C} \). An element \( f \in \text{Hom}_{\text{alg}}(H, \mathbb{C}) \) is determined by the images \( c_i := f(p_i^*) \) for all \( i \geq 1 \).

It is well known (see e.g. [Ab, §3.4]) that \( \text{Hom}_{\text{alg}}(H, \mathbb{C}) \) can also be identified with the group \( G(H^\circ) \) of all group-like elements of the dual Hopf algebra \( H^\circ \) of \( H \), by mapping \( f \in \text{Hom}_{\text{alg}}(H, \mathbb{C}) \) to

\[
y_f = \sum_m \left( \prod_i c_i^{m_i} \right) p_m \in G(H^\circ).
\]

Note that the map \( f \mapsto y_f \) does not depend on the choice of the PBW-basis \( P = \{ p_m \mid m \in \mathbb{N}^{(J)} \} \). Note also that \( G(H^\circ) \) is contained in the vector space dual \( H^* \) of \( H \), which is the completion \( \hat{U}(n) \) of \( U(n) \) with respect to its natural grading. When we use this second identification, an element \( x \in N = \hat{n} \) is simply represented by the group-like element

\[
\exp(x) := \sum_{k \geq 0} x^k/k!
\]

in \( \hat{U}(n) \). To summarize, we have \( H = U(n)^*_g \equiv \mathbb{C}[N] \) and

\[
N \equiv \text{maxSpec}(H) \equiv \text{Hom}_{\text{alg}}(H, \mathbb{C}) \equiv G(H^\circ) \subset H^\circ \subset H^* \equiv \hat{U}(n).
\]

5.2. The unipotent groups \( N(w) \) and \( N'(w) \). Let \( \Theta \) be a bracket closed subset of \( \Delta^+ \), and let

\[
N(\Theta) := \text{Exp}(\hat{n}(\Theta))
\]

be the corresponding pro-unipotent pro-group. For example, if \( \alpha \in \Delta^+_t \), then \( \Theta_\alpha := \{ \alpha \} \) is bracket closed. In this case, \( N(\alpha) \) is called the one-parameter subgroup of \( N \) associated to \( \alpha \). We have an isomorphism of groups \( N(\alpha) \cong (\mathbb{C}, +) \).

If \( \Theta \) is bracket closed and bracket coclosed, then set \( N'(\Theta) := N(\Delta^+ \setminus \Theta) \). In this case, the multiplication in \( N \) yields a bijection [Ku, Lemma 6.1.2]

\[
m: N(\Theta) \times N'(\Theta) \to N.
\]

For \( w \in W \) let \( N(w) := N(\Delta^+_w) \). This is a unipotent algebraic group of dimension \( l(w) \), and its Lie algebra is \( n(w) \). Again we can identify \( U(n(w))^*_g \equiv \mathbb{C}[N(w)] \). Similarly, define \( N'(w) := N'(\Delta^+_w) \).
6. Evaluation functions and generating functions of Euler characteristics

Recall the identifications $\mathcal{M}^* \equiv U(\mathfrak{n})_{\text{gr}}^* = \mathbb{C}[N]$. To every $X \in \text{nil}(\Lambda)$, we have associated a linear form $\delta_X \in U(\mathfrak{n})_{\text{gr}}^*$. We shall also denote the evaluation function $\delta_X$ by $\varphi_X$ when we regard it as a function on $N$. For $1 \leq i \leq n$ define $x_i: \mathbb{C} \to N$ by

$$x_i(t) := \exp(te_i) = \sum_{k \geq 0} \frac{(te_i)^k}{k!}$$

The following formula shows how to evaluate $\varphi_X$ on a product of $x_i(t)$'s.

**Proposition 6.1.** Let $X \in \text{nil}(\Lambda)$, and let $\mathbf{i} = (i_1, \ldots, i_k)$ be any sequence with $1 \leq i_j \leq n$ for all $1 \leq j \leq k$. We have

$$\varphi_X(x_{i_1}(t_1) \cdots x_{i_k}(t_k)) = \sum_{\mathbf{a} = (a_1, \ldots, a_k) \in \mathbb{N}^k} \chi_c(F_{i^\mathbf{a},X}) \frac{t_1^{a_1} \cdots t_k^{a_k}}{a_1! \cdots a_k!}.$$ 

Here $\mathbf{i}^\mathbf{a}$ is short for the sequence $(i_1, \ldots, i_1, \ldots, i_k, \ldots, i_k)$ consisting of $a_1$ letters $i_1$ followed by $a_2$ letters $i_2$, etc.

**Proof.** By Section 5.1 we can regard $x_{i_1}(t_1) \cdots x_{i_k}(t_k)$ as an element of $U(\mathfrak{n})$, namely,

$$x_{i_1}(t_1) \cdots x_{i_k}(t_k) = \sum_{\mathbf{a} = (a_1, \ldots, a_k) \in \mathbb{N}^k} \frac{t_1^{a_1} \cdots t_k^{a_k}}{a_1! \cdots a_k!} e_{i_1}^{a_1} \cdots e_{i_k}^{a_k}.$$ 

It follows from the identification of $\varphi_X$ with $\delta_X$ that

$$\varphi_X(x_{i_1}(t_1) \cdots x_{i_k}(t_k)) = \sum_{\mathbf{a} = (a_1, \ldots, a_k) \in \mathbb{N}^k} \frac{t_1^{a_1} \cdots t_k^{a_k}}{a_1! \cdots a_k!} \delta_X(e_{i_1}^{a_1} \cdots e_{i_k}^{a_k}).$$

Now, in the geometric realization $\mathcal{M}$ of the enveloping algebra $U(\mathfrak{n})$ in terms of constructible functions, $e_{i_1}^{a_1} \cdots e_{i_k}^{a_k}$ becomes the convolution product $1_{i_1}^{a_1} \ast \cdots \ast 1_{i_k}^{a_k}$ and it is easy to see that

$$\delta_X(1_{i_1}^{a_1} \ast \cdots \ast 1_{i_k}^{a_k}) = \chi_c(F_{i^\mathbf{a},X}).$$

This finishes the proof. \hfill \Box

**Remark 6.2.** The formula for $\varphi_X$ given in [GLS5] §9 involves descending flags instead of ascending flags of submodules of $X$. This is because in the present paper we have taken a convolution product $\ast$ opposite to that of our previous papers, see Remark 2.3.

Proposition 6.1 says that we can think of the $\varphi$-functions $\varphi_X$ as generating functions of Euler characteristics.

For $\mathbf{i} = (i_1, \ldots, i_k)$ and $\mathbf{a} = (a_1, \ldots, a_k)$ as above and $X \in \text{nil}(\Lambda)$ let $F_{i^\mathbf{a},X}$ be the projective variety of partial composition series of type $(\mathbf{i}, \mathbf{a})$ of $X$. Thus an element of $F_{i^\mathbf{a},X}$ is a chain

$$0 = X_0 \subseteq X_1 \subseteq \cdots \subseteq X_k = X$$

of submodules of $X$ such that $X_j/X_{j-1} \cong \mathbb{C}^{a_j}$ for all $1 \leq j \leq k$. There is an obvious surjective morphism $\pi_{i^\mathbf{a},X}: F_{i^\mathbf{a},X} \to F_{i^\mathbf{a},X}$ whose fibers are all isomorphic to

$$F(\mathbb{C}^{a_1}) \times \cdots \times F(\mathbb{C}^{a_k}),$$

where $F(\mathbb{C}^m)$ is the variety of complete flags of subspaces in $\mathbb{C}^m$. In particular, we have

$$\chi_c(F_{i^\mathbf{a},X}) = \chi_c(F_{i^\mathbf{a},X}) a_1! \cdots a_k!.$$
Summarizing, we get
\[ \varphi_X(x_{i_1}(t_1) \cdots x_{i_k}(t_k)) = \sum_{a=(a_1, \ldots, a_k) \in \mathbb{N}^k} \chi_c(F_{i_k,a}x) t_1^{a_1} \cdots t_k^{a_k}. \]

7. Generalized minors

7.1. Generalized minors. We start with some generalities on Kac-Moody groups. Let \( G^{\min} \) be the Kac-Moody group with \( \text{Lie}(G^{\min}) = \mathfrak{g} \) defined in [Ku 7.4]. It has a refined Tits system
\[(G^{\min}, \text{Norm}_{G^{\min}}(H), N \cap G^{\min}, N_-, H).\]
Write \( N^{\min} := G^{\min} \cap N \). Moreover, \( G^{\min} \) is an affine ind-variety in a unique way [Ku 7.4.8].

For any real root \( \alpha \) of \( \mathfrak{g} \), the one-parameter subgroup \( N(\alpha) \) is contained in \( G^{\min} \), and the \( N(\alpha) \) together with \( H \) generate \( G^{\min} \) as a group. We have an anti-automorphism \( g \mapsto g^T \) of \( G^{\min} \) which maps \( N(\alpha) \) to \( N(-\alpha) \) for each real root \( \alpha \), and fixes \( H \). We have another anti-automorphism \( g \mapsto g' \) which fixes \( N(\alpha) \) for every real root \( \alpha \), and \( h' = h^{-1} \) for every \( h \in H \).

For each \( \gamma \in \mathfrak{h}^* \) there is a character \( H \to \mathbb{C}^*, a \mapsto a^\gamma \) defined by \( \exp(h)\gamma := e^{\gamma(h)} \) for all \( h \in \mathfrak{h} \).

For \( 1 \leq i \leq n \) we have a unique homomorphism \( \varphi_i : SL_2(\mathbb{C}) \to G^{\min} \) satisfying
\[ \varphi_i \left( \begin{array}{cc} 1 & t \\ 0 & 1 \end{array} \right) = \exp(te_i), \quad \varphi_i \left( \begin{array}{cc} 1 & t \\ t & 1 \end{array} \right) = \exp(tf_i), \quad (t \in \mathbb{C}). \]

We define
\[ \overline{\varphi}_i := \varphi_i \left( \begin{array}{cc} 0 & -1 \\ 1 & 0 \end{array} \right). \]

For \( w \in W \), we define \( \overline{w} := \overline{\varphi}_i \cdots \overline{\varphi}_i \), where \((i_r, \ldots, i_1)\) is a reduced expression for \( w \). Thus, we choose for every \( w \in W \) a particular representative \( \overline{w} \) of \( w \) in the normalizer \( \text{Norm}_{G^{\min}}(H) \).

Let \( L(\lambda) \) denote the irreducible highest weight \( \mathfrak{g} \)-module with highest weight \( \lambda \in P^+ \). Let \( u_\lambda \) be a highest weight vector of \( L(\lambda) \). This is an integrable module, so it is also a representation of \( G^{\min} \). For a reduced expression \( i = (i_r, \ldots, i_1) \) of a Weyl group element \( w \), the vector
\[ \overline{\varphi}_{i_r} \cdots \overline{\varphi}_{i_1}(u_\lambda) \in L(\lambda) \]
is an extremal weight vector of \( L(\lambda) \), i.e. it belongs to the extremal weight space \( L(\lambda)_w(\lambda) \). For a \( U(\mathfrak{g}) \)-module \( V \) and a weight vector \( v \in V_\mu \) define
\[ f_i^{\mu} v := f_i^{(m)} v \]
where \( m \geq 0 \) is maximal such that \( f_i^{(m)} v \neq 0 \). Similarly, define \( e_i^{\mu} \). The following results can be found in [Jo, Section 4.4.3]: We have
\[ \overline{\varphi}_{i_1} \overline{\varphi}_{i_2} \cdots \overline{\varphi}_{i_r}(u_\lambda) = f_{i_1}^{\mu} f_{i_2}^{\mu} \cdots f_{i_r}^{\mu}_r(u_\lambda) \]
and
\[ e_{i_r} f_{i_2}^{\mu} \cdots f_{i_r}^{\mu}(u_\lambda) = 0. \]
Furthermore,
\[ \text{wt}(\overline{\varphi}_{i_1} \cdots \overline{\varphi}_{i_r}(u_\lambda)) = \text{wt}(\overline{\varphi}_{i_2} \cdots \overline{\varphi}_{i_r}(u_\lambda)) - b_1 \alpha_{i_1} \]
where \( b_1 := -(s_{i_1} \cdots s_{i_r}(\lambda), \alpha_{i_1}) = (s_{i_2} \cdots s_{i_r}(\lambda), \alpha_{i_1}). \)
We have the following analogue of the Gaussian decomposition.

**Proposition 7.1.** Let $G_0$ be the subset $N_\cdot H \cdot N^\min$ of $G^\min$.

(i) The subset $G_0$ is dense open in $G^\min$ and each element $g \in G_0$ admits a unique factorization $g = [g]^0g^+ \in N_\cdot H \cdot N^\min$, with $[g]^0 \in H$ and $[g]^+ \in N^\min$.

(ii) The map $g \mapsto [g]^0$ (resp. $g \mapsto [g]^+$) is a morphism of ind-varieties from $G_0$ to $N^\min$ (resp. to $H$).

Part (i) follows from the fundamental properties of a refined Tits system [Ku, Theorem 5.2.3]. For part (ii), see [Ku, Proposition 7.4.11].

Following Fomin and Zelevinsky [FZ1] we can now define for each $\varpi_j$ a generalized minor $\Delta_{\varpi_j,\varpi_j}$ as the regular function on $G^\min$ such that

\[
\Delta_{\varpi_j,\varpi_j}(g) = [g]^0_{\varpi_j}, \quad (g \in G_0).
\]

For $w \in W$, we also define $\Delta_{\varpi_j, w(\varpi_j)}$ by

\[
\Delta_{\varpi_j, w(\varpi_j)}(g) := \Delta_{\varpi_j, \varpi_j}(gw).
\]

The generalized minors $\Delta_{\varpi_j, \varpi_j}(g)$ have the following alternative description.

**Proposition 7.2.** Let $g \in G^\min$. The coefficient of $u_{\varpi_j}$ in the projection of $gu_{\varpi_j}$ on the weight space $L(\varpi_j)$ is equal to $\Delta_{\varpi_j, \varpi_j}(g)$.

**Proof.** Set $u_j := u_{\varpi_j}$. Let $g = [g]^0[g]^+ \in G_0$. We have $[g]^0u_j = u_j$, and $[g]^0u_j = [g]^0_{\varpi_j}u_j$. The result then follows from the fact that $[g]^0u_j$ is equal to $u_j$ plus elements in lower weights. \hfill $\square$

**Proposition 7.3.** We have

\[
G_0 = \{ g \in G^\min \mid \Delta_{\varpi_j, \varpi_j}(g) \neq 0 \text{ for all } 1 \leq j \leq n \}.
\]

**Proof.** Set $u_j := u_{\varpi_j}$. We use the Birkhoff decomposition [Ku, Theorem 5.2.3]

\[
G^\min = \bigsqcup_{w \in W} N_\cdot \varpi H N^\min,
\]

where $G_0$ is the subset of the right-hand side corresponding to $w = e$. If $g = [g]^0[g]^+ \in G_0$, then $\Delta_{\varpi_j, \varpi_j}(g) = [g]^0_{\varpi_j} \neq 0$. Conversely, if $g \notin G_0$ we have $g = n_\cdot w H n_\cdot w$ for some $n_\cdot \in N_\cdot$, $n_\cdot \in N^\min$, $h \in H$ and $w \neq e$. Then for some $j$ we have $w(\varpi_j) \neq \varpi_j$ and $\varpi H n u_j$ is a multiple of the extremal weight vector $\varpi u_j$. Since the projection of $n_\cdot w u_j$ on the highest weight space of $L(\varpi_j)$ is zero, it follows that $\Delta_{\varpi_j, \varpi_j}(g) = 0$. Finally, note that for any $j > n$ the minor $\Delta_{\varpi_j, \varpi_j}$ does not vanish on $G^\min$. Indeed, the corresponding highest weight irreducible module $L(\varpi_j)$ is one-dimensional since $\varpi_j(\alpha_i^\vee) = 0$ for any $i$. Hence in the above description of $G_0$, we may omit the minors $\Delta_{\varpi_j, \varpi_j}$ with $j > n$. \hfill $\square$

### 7.2. The module $L(\lambda)$ as a subspace of $\mathbb{C}[N]$.

For $w \in W$ and $1 \leq j \leq n$, we denote by

\[
D_{\varpi_j, w(\varpi_j)}
\]

the restriction of the generalized minor $\Delta_{\varpi_j, w(\varpi_j)}$ to $N^\min$. For example, $D_{\varpi_j, \varpi_j}$ is equal to the constant function $1$. In Section 9.1 we are going to show that each (restricted) generalized minor $D_{\varpi_j, w(\varpi_j)}$ can be identified with a generating function $\varphi_X$ for a certain $\Lambda$-module $X$. In order to do this, we need to recall some results on Kac-Moody groups.
Let $G' := [G_{\text{min}}, G_{\text{min}}]$ be the group constructed by Kac and Peterson \cite{KP}, see \cite{Ku} Section 7.4.E (1)]. The associated Lie algebra is $\mathfrak{g}' = [\mathfrak{g}, \mathfrak{g}]$.

Let $\mathbb{C}[G']_{s.r.}$ denote the algebra of strongly regular functions on $G'$ \cite{KP} §2C. Define the invariant ring
\[
\mathbb{C}[N_- \backslash G']_{s.r.} := \{ f \in \mathbb{C}[G']_{s.r.} \mid f(ng) = f(g) \text{ for all } n \in N_-, \ g \in G' \}.
\]
This ring is endowed with the usual left action of $G'$ given by
\[(g \cdot f)(g') := f(g'g), \quad (f \in \mathbb{C}[N_- \backslash G']_{s.r.}, \ g, g' \in G').\]

It was proved by Kac and Peterson \cite{KP} Corollary 2.2 that as a left $G'$-module, it decomposes as follows
\[
\mathbb{C}[N_- \backslash G']_{s.r.} = \bigoplus_{\lambda \in \overline{P}^+} L(\lambda).
\]
This is a multiplicity-free decomposition, in which the irreducible highest weight module $L(\lambda)$ is carried by the subspace
\[
S(\lambda) = \{ f \in \mathbb{C}[N_- \backslash G']_{s.r.} \mid f(hg) = \Delta_\lambda(h)f(g) \text{ for all } h \in H, \ g \in G' \},
\]
where we denote
\[
\Delta_\lambda := \prod_{j=1}^n \Delta^\lambda(\alpha^j)_{\omega_j, \omega_j}.
\]
Clearly, $\Delta_\lambda$ is contained in $S(\lambda)$, and it is a highest weight vector. Moreover, for any $w \in W$, the 1-dimensional extremal weight space of $S(\lambda)$ with weight $w(\lambda)$ is spanned by
\[
\Delta_{w(\lambda)} := \prod_{j=1}^n \Delta^\lambda(\alpha^j)_{\omega_j, w(\omega_j)}.
\]

Now consider the restriction map
\[
\rho: \mathbb{C}[N_- \backslash G']_{s.r.} \to \mathbb{C}[N_{\text{min}}]_{s.r.}
\]
given by restriction of functions from $G'$ to $N_{\text{min}}$.

**Lemma 7.4.** For every $\lambda \in \overline{P}^+$, the restriction
\[
\rho_\lambda: S(\lambda) \to \mathbb{C}[N_{\text{min}}]_{s.r.}
\]
of $\rho$ to $S(\lambda)$ is injective.

**Proof.** Let $B'_-$ be the Borel subgroup of $G'$ with unipotent radical $N_-$. We have
\[
N_{\text{min}} \subset G_0 \cap G' = B'_- N_{\text{min}}.
\]
It follows that the natural projection from $G'$ onto $B'_- \backslash G'$ restricts to an embedding of $N_{\text{min}}$, with image the open subset of the flag variety $\mathcal{X} = B'_- \backslash G'$ defined by the non-vanishing of the minors $\Delta_{\omega_j, \omega_j}$. Now $\mathbb{C}[N_- \backslash G']_{s.r.}$ can be regarded as the multi-homogeneous coordinate ring of $\mathcal{X}$ with homogeneous components $S(\lambda)$, where $\lambda$ runs through $\overline{P}^+$. It follows that $\mathbb{C}[N_{\text{min}}]$ can be identified with the subring of degree 0 homogeneous elements of the localized ring obtained from $\mathbb{C}[N_- \backslash G']_{s.r.}$ by formally inverting the element
\[
\Delta := \prod_{j=1}^n \Delta_{\omega_j, \omega_j}.
\]
Therefore, the restriction $\rho_\lambda$ of $\rho$ to every homogeneous piece $S(\lambda)$ is an embedding. \qed
It follows that we can transport the $G'$-module structure from $S(\lambda)$ to $\rho(S(\lambda))$ by setting

$g \cdot \varphi := \rho(g \cdot \rho^{-1}_\lambda(\varphi)), \quad (g \in G', \ \varphi \in \rho(S(\lambda))).$

In this way, we can identify the highest weight module $L(\lambda)$ with the subspace $\rho(S(\lambda))$ of $\mathbb{C}[N_{\text{min}}]_{s.r.}$. The highest weight vector is now $\rho(\Delta_{\lambda}) = 1$, and the extremal weight vectors are the (restricted) generalized minors

$$D_w(\lambda) := \prod_{j=1}^n D_\lambda^{(\alpha_j^w)}(w(\alpha_j)),$$

for $w \in W$.

At this point, we note that a strongly regular function on $N_{\text{min}}$ is just the same as an element of $U(n)^*_{\text{gr}}$. Indeed, the elements of $\mathbb{C}[N_{\text{min}}]_{s.r.}$ are the restrictions to $N_{\text{min}}$ of the linear combinations of matrix coefficients of the irreducible integrable representations $L(\lambda)$ with $\lambda \in \overline{P}^+$ of $G'$, see [KP, Lemma 4.2]. Now, by Theorem 4.4, we can realize every $L(\lambda)$ as a subspace of $U(n)^*_{\text{gr}}$, and every $f \in U(n)^*_{\text{gr}}$ belongs to such a subspace for $\lambda = \sum_{i=1}^n l_i \alpha_i$ with the $l_i \gg 0$. It follows that each element of $U(n)^*_{\text{gr}}$ can be seen as a matrix coefficient for some $L(\lambda)$, and vice versa. We can therefore identify

$$\mathbb{C}[N_{\text{min}}]_{s.r.} \equiv U(n)^*_{\text{gr}} \equiv \mathbb{C}[N].$$

Moreover, these two ways of embedding $L(\lambda)$ in $\mathbb{C}[N]$ coincide.

**Lemma 7.5.** Let $\lambda \in \overline{P}^+$. Under the identification $U(n)^*_{\text{gr}} \equiv \mathbb{C}[N_{\text{min}}]_{s.r.}$, the subspace $U(\lambda)$ defined in Theorem 4.4 coincides with $\rho(S(\lambda))$.

**Proof.** The natural right action of $U(n)$ on $U(n)^*_{\text{gr}}$ defined before Corollary 4.5 coincides with the right action of $U(n)$ on $\mathbb{C}[N_{\text{min}}]_{s.r.}$ obtained by differentiating the right regular representation of $N_{\text{min}}$.

$$(f \cdot n)(x) = f(nx), \quad (x, n \in N_{\text{min}}, \ f \in \mathbb{C}[N_{\text{min}}]_{s.r.}).$$

Consider first the case of a fundamental weight $\lambda = \varpi_j$. It is easy to check that

$$\Delta_{\varpi_j, \varpi_j}(x_i(t)g) = \begin{cases} \Delta_{\varpi_j, \varpi_j}(g) & \text{if } i \neq j, \\ \Delta_{\varpi_j, \varpi_j}(g) + t \Delta_{\varpi_j}(\varpi_j)g & \text{if } i = j. \end{cases}$$

Now, the subspace $\rho(S(\lambda))$ is spanned by the functions $n \mapsto \Delta_{\varpi_j, \varpi_j}(ng), \ (n \in N_-, \ g \in G')$. By differentiating the previous equation with respect to $t$ and setting $t = 0$, we obtain that

$$\rho(S(\lambda)) \subseteq \{ f \in \mathbb{C}[N_{\text{min}}]_{s.r.} \mid f \cdot e_i = 0 \text{ for } i \neq j, \ f \cdot e_j^2 = 0 \} .$$

Hence, using Corollary 4.5, we see that $\rho(S(\lambda))$ is contained in the embedding of $L(\varpi_j)$ into the dual Verma module $M^*_{\text{low}}(\varpi_j)$. Since these spaces have the same graded dimensions, they must coincide. The case of a general $\lambda \in \overline{P}^+$ follows using the fact that

$$\Delta_{\lambda} = \prod_{j=1}^n \Delta_{\varpi_j, \varpi_j}^{(\alpha_j^\lambda)},$$

and that the $e_i$’s act as derivations on $\mathbb{C}[N_{\text{min}}]_{s.r.}$. \hfill $\square$
8. The coordinate rings $\mathbb{C}[N(w)]$ and $\mathbb{C}[N^w]$

8.1. The coordinate ring $\mathbb{C}[N(w)]$ as a ring of invariants. Again, we fix a reduced expression $i = (i_r, \ldots, i_1)$ of a Weyl group element $w$. Assume that

$$\mathcal{P} = \{p_m \mid m \in \mathbb{N}^{(J)}\}$$

is an $i$-compatible PBW-basis of $U(n)$. Note that this PBW-basis of $U(n)$ and also the corresponding dual PBW-basis of $(U(n))^*_\mathfrak{g}$ are homogeneous with respect to the (root lattice) $\mathbb{N}^n$-grading of $U(n)$. We write $|m| = d \in \mathbb{N}^n$ in case $p_m$ is a homogeneous element of degree $d \in \mathbb{N}^n$. Let us denote by $(e_i)_{i \in J}$ the usual coordinate vectors of $\mathbb{Z}^{(J)}$. For example, $|e_k| = \beta_i(k)$ for $1 \leq k \leq r$.

The multiplication $\mu: U(n) \otimes U(n) \rightarrow U(n)$ is given by its effect on the PBW-basis, say

$$p_m \cdot p_n = \sum_{|k| = |m+n|} c_{m,n,k} p_k.$$

Next, the comultiplication $\mu^*: \mathbb{C}[N] \rightarrow \mathbb{C}[N] \otimes \mathbb{C}[N]$ is a ring homomorphism, so it is determined by the value on the generators $n_i^* = p_{e_i}^*$. By construction, we have

$$\mu^*(p_i^*) = \sum_{|m+n| = |e_i|} c_{i,n,m} (p_m^* \otimes p_n^*).$$

**Lemma 8.1.** Let $1 \leq i \leq r$ and $0 \neq n \in \mathbb{N}^{(J)}$ such that $n_j = 0$ for $1 \leq j \leq r$. Then $c_{i,n,m} = 0$.

**Proof.** Let $m = m^< + m^>$ such that $m_j^< = 0$ for $j > r$ and $m_j^> = 0$ for $1 \leq j \leq r$, so $p_m = p_m^< \cdot p_m^>$. Since $\Delta_m^*$ is bracket closed and coclosed we have

$$p_m^> \cdot p_n = \sum_{|k'| = |m^> + n|} c_{m^>,n,k'} k'^<$$

with $k_j' = 0$ for $1 \leq j \leq r$. Thus

$$p_m \cdot p_n = \sum_{|k'| = |m^> + n|} c_{m^>,n,k'} k'^<.$$

Putting $k = k' + m^<$ we get $c_{i,n,m} = c_{i,n,k^>}$. Thus, if in our situation $c_{i,n,m} \neq 0$ then $k_j \neq 0$ for some $k > r$. \qed

Now, let us turn to the subgroups $N(w)$ and $N'(w)$. Consider the ideals

$$I(w) := (p_{r+1}^*, p_{r+2}^*, \ldots), \quad I'(w) := (p_1^*, \ldots, p_r^*)$$

in $\mathbb{C}[N]$. Then we have

$$N(w) = \{\nu \in \mathrm{Hom}_{\mathrm{alg}}(\mathbb{C}[N], \mathbb{C}) \mid \nu(I(w)) = 0\}, \quad \text{and}$$

$$N'(w) = \{\nu' \in \mathrm{Hom}_{\mathrm{alg}}(\mathbb{C}[N], \mathbb{C}) \mid \nu'(I'(w)) = 0\}.$$  

In other words we have canonically $\mathbb{C}[N(w)] = \mathbb{C}[N]/I(w)$ and $\mathbb{C}[N'(w)] = \mathbb{C}[N]/I'(w)$.

We consider the action of $N'(w)$ on $N$ via right multiplication. By definition, this comes from the left action of $N'(w)$ on $\mathbb{C}[N]$ given by

$$\nu' \cdot f = (\mathrm{id} \otimes \nu')\mu^*(f)$$

for $f \in \mathbb{C}[N]$ and $\nu' \in N'(w)$. (Here we identify $\mathbb{C}[N] \otimes \mathbb{C} \equiv \mathbb{C}[N]$ in the canonical way.)
We denote by $\mathbb{C}[N]^{N'(w)}$ the invariant subring for this group action.

**Proposition 8.2.** Consider the injective ring homomorphism

$$\tilde{\pi}_w^*: \mathbb{C}[N(w)] \to \mathbb{C}[N]$$

defined by $p_i^* + I(w) \mapsto p_i^*$ for $1 \leq i \leq r$. The corresponding morphism (of schemes) $\tilde{\pi}_w: N \to N(w)$ is $N'(w)$-invariant and is a retraction for the inclusion of $N(w)$ into $N$. As a consequence, $\tilde{\pi}_w^*$ identifies $\mathbb{C}[N(w)]$ with $\mathbb{C}[N]^{N'(w)} = \mathbb{C}[p_1^*, \ldots, p_r^*]$. 

**Proof.** We have

$$\mu^*(p_i^*) = 1 \otimes p_i^* + p_i^* \otimes 1 + \sum_{|m+n|=|e_i|} c_{m,n}^i (p_m^* \otimes p_n^*)$$

where in the last sum $|m| \neq 0 \neq |n|$. Thus for $1 \leq i \leq r$ and $\nu' \in N'(w)$ we get

$$\nu' \cdot p_i^* = 1 \cdot 0 + p_i^* \cdot 1 + \sum_{|m+n|=|e_i|} c_{m,n}^i p_m^* \cdot \nu'(p_n^*)$$

with the last sum vanishing by Lemma 8.3 and the definition of $N'(w)$. In other words, $p_i^* \in \mathbb{C}[N]^{N'(w)}$ for $1 \leq i \leq r$. Thus, $\tilde{\pi}_w: N \to N(w)$ is $N'(w)$-invariant, that is, $\tilde{\pi}_w(nn') = \tilde{\pi}_w(n)$ for any $n' \in N'(w)$.

Now, since the multiplication map $N(w) \times N'(w) \to N$ is bijective, each $N'(w)$-orbit on $N$ is of the form $n \cdot N'(w)$ for a unique $n \in N(w)$. We conclude that the inclusion $N(w) \hookrightarrow N$ is for a section for $\tilde{\pi}_w$. Our claim follows. 

8.2. **The coordinate ring $\mathbb{C}[N^w]$ as a localization of $\mathbb{C}[N]^{N'(w)}$.** Let us now consider the groups $N(w)$ and $N'(w)$ introduced in Section 5.2

**Lemma 8.3.** We have

$$N(w) = N \cap (w^{-1}Nw),$$

$$N'(w) = N \cap (w^{-1}Nw),$$

$$N'(w) \cap N^{\min} = N^{\min} \cap (w^{-1}N^{\min}w).$$

**Proof.** This follows from [Ku 5.2.3] and [Ku 6.2.8]. 

It follows that $\Delta_{w_j, w^{-1}(w_j)}$ is invariant under the action of $N'(w) \cap N^{\min}$ on $G^{\min}$ via right multiplication. Indeed, for $g \in G^{\min}$ and $n' \in N'(w) \cap N^{\min}$, we have $n'w^{-1} = w^{-1}n''$ for some $n'' \in N'(w) \cap N^{\min}$, hence

$$\Delta_{w_j, w^{-1}(w_j)}(gn') = \Delta_{w_j, w^{-1}(w_j)}(gwn') = \Delta_{w_j, w^{-1}(w_j)}(gw^{-1}n'')$$

$$= \Delta_{w_j, w^{-1}(w_j)}(gw^{-1}) = \Delta_{w_j, w^{-1}(w_j)}(g).$$

Define

$$O_w := \left\{ n \in N^{\min} \mid \Delta_{w_j, w^{-1}(w_j)}(n) \neq 0 \text{ for all } 1 \leq j \leq n \right\}.$$

This is the open subset of $N^{\min}$ consisting of elements $n$ such that $\varpi n^T \in G_0$. Indeed,

$$\Delta_{w_j, w^{-1}(w_j)}(n) = \Delta_{w_j, w^{-1}(w_j)}(n^{-1}w^{-1}) = \Delta_{w_j, w^{-1}(w_j)}(n^{-1}w^{-1}) = \Delta_{w_j, w^{-1}(w_j)}(w^{-1}n^T),$$

since $w^{-1} = w^{-1}$. Following [BZ, Section 5], we can now define the map $\tilde{\eta}_w: O_w \to N^{\min}$ given by

$$\tilde{\eta}_w(z) := [\varpi z^T].$$

Recall that $N^w = N \cap (B_-wB_-)$, see Section 3.4.
Proposition 8.4. The following properties hold:

(i) The map \( \tilde{\eta}_w \) is a morphism of ind-varieties.
(ii) The image of \( \tilde{\eta}_w \) is \( N^w \).
(iii) \( \tilde{\eta}_w(x) = \tilde{\eta}_w(y) \) if and only if \( x = y n' \) for some \( n' \in N'(w) \cap N^{\min} \).
(iv) \( \tilde{\eta}_w \) restricts to a bijective morphism \( N(w) \cap O_w \rightarrow N^w \).
(v) We have \( N^w \subset O_w \), and \( \tilde{\eta}_w \) restricts to a bijection \( \eta_w : N^w \rightarrow N^w \).
(vi) The inverse of \( \eta_w \) is given by \( \eta_w^{-1}(x) = \eta_{w^{-1}}(x^t) \) for \( x \in N^w \). It follows that \( \eta_w \) is an automorphism of \( N^w \).

Proof. Property (i) follows from Proposition [7,1] (ii). Next, we have

\[
[wz^T]^+ = ([wz^T]_0^{-1}[wz^T]_1^{-1})wz^T \in B_+ \bar{w}B_-
\]

This shows that the image of \( \tilde{\eta}_w \) is contained in \( N^w \). The rest of (ii) and (iii) is proved as in [BZ], Proposition 5.1. Property (iv) follows from (ii), (iii), and the decomposition \( N^{\min} = N(w) \times (N'(w) \cap N^{\min}) \). Finally, (v) and (vi) are proved exactly in the same way as in [BZ], Propositions 5.1, 5.2.

Proposition 8.5. The map \( \tilde{\pi}_w \) restricts to a morphism \( \pi_w : N^w \rightarrow O_w \cap N(w) \). This is an isomorphism with inverse

\[
\eta_{w^{-1}}\tilde{\eta}_w : O_w \cap N(w) \rightarrow N^w.
\]

In particular, \( N^w \) is an affine variety with coordinate ring identified to the localized ring \( \mathbb{C}[N]_{\Delta_w}^{N^w(w)} \), where

\[
\Delta_w := \prod_{j=1}^n \Delta_{w_j, w^{-1}(w_j)}.
\]

Proof. By Proposition 8.4 (iv) and (v), we know that \( \eta_{w^{-1}}\tilde{\eta}_w \) is a bijection. On the other hand \( \tilde{\pi}_w(N^w) \subseteq O_w \cap N(w) \) because \( N^w \subseteq O_w \). Now, by Proposition 8.4 (iii), we have

\[
\tilde{\eta}_w(\pi_w(x)) = \tilde{\eta}_w(x) = \eta_w(x)
\]

for every \( x \in N^w \). Hence \( \eta_{w^{-1}}\tilde{\eta}_w\pi_w(x) = x \) for every \( x \in N^w \). So we have \( \eta_{w^{-1}}\tilde{\eta}_w\pi_w = \text{id}_{N^w} \), and this proves that \( \pi_w \) is the inverse of \( \eta_{w^{-1}}\tilde{\eta}_w \).

These maps are morphisms of varieties so they induce isomorphisms

\[
\mathbb{C}[N^w] \xrightarrow{\sim} \mathbb{C}[N(w) \cap O_w] = \mathbb{C}[N(w)]_{\Delta_w} \xrightarrow{\sim} \mathbb{C}[N]_{\Delta_w}^{N^w(w)}.
\]

The following commutative diagram displays the different morphisms appearing in Propositions 8.4 and 8.5:

\[
\begin{array}{ccc}
N & \xrightarrow{\tilde{\pi}_w} & N(w) \\
\downarrow{\iota} & & \downarrow{\iota} \\
N^w & \xrightarrow{\pi_w} & N(w) \cap O_w \xrightarrow{\sim} N^w \\
\end{array}
\]

\[
\begin{array}{ccc}
O_w & \xrightarrow{\tilde{\eta}_w} & N^{\min} \\
\downarrow{\iota} & & \downarrow{\iota} \\
N^w & \xrightarrow{\eta_w} & N(w) \cap O_w \xrightarrow{\sim} N^w \\
\end{array}
\]

(THE ARROWS LABELLED WITH \( \iota \) ARE INCLUSION MAPS.)
9. The modules $V_k$ and $M_k$

For the entire section, we fix a reduced expression $i = (i_r, \ldots, i_1)$ of a Weyl group element $w$, and as before let $V_i = V_1 \oplus \cdots \oplus V_r$ and $M_i = M_1 \oplus \cdots \oplus M_r$. Recall that for each $1 \leq k \leq r$ there is a short exact sequence

$$0 \to V_{k^-} \to V_k \to M_k \to 0$$

of $\Lambda$-modules.

9.1. Generalized minors as $\varphi$-functions. For $1 \leq k \leq r$ set

$$w_{\leq k}^{-1} := s_{i_1} \cdots s_{i_k}.$$

**Proposition 9.1.** For $1 \leq k \leq r$ we have

$$\varphi_{V_k} = D_{\varpi_{ik}, w_{\leq k}^{-1}(\varpi_{ik})}.$$

In particular, we have $\varphi_{\Lambda_{ij}} = D_{\varpi_{ij}, w_{\leq j}^{-1}(\varpi_{ij})}$ for every $1 \leq j \leq n$.

**Proof.** Using Lemma 7.5 we can realize the fundamental module $L(\varpi_{ik})$ as the subspace $\rho(S(\varpi_{ik}))$ of $\mathbb{C}[N]$. Then using Theorem 4.3, the definition of $V_k$ (see Section 2.4) and the discussion in Section 7.1 we can check that the function $\varphi_{V_k}$ is an extremal weight vector of weight $w_{\leq k}^{-1}(\varpi_{ik})$ in $L(\varpi_{ik})$, hence it coincides with $D_{\varpi_{ik}, w_{\leq k}^{-1}(\varpi_{ik})}$ up to a scalar. Moreover, its image under $e_i^{max} \cdots e_1^{max}$ is equal to 1, so the normalizations agree and we have $\varphi_{V_k} = D_{\varpi_{ik}, w_{\leq k}^{-1}(\varpi_{ik})}$.

**Corollary 9.2.** For $1 \leq k \leq r$ we have $\dim(V_k) = \varpi_{ik} - s_{i_1} s_{i_2} \cdots s_{i_k}(\varpi_{ik})$.

**Proof.** The statement follows from the following general fact: Assume that $\delta_X \in U(\lambda)$ for some weight $\lambda \in P^+$ and some $\Lambda$-module $X$. When we consider $\delta_X$ as an element of $L(\lambda) \equiv U(\lambda)$, Theorem 4.4 implies that $\text{wt}(\delta_X) = \lambda - \dim(X)$.

Recall that for $1 \leq k \leq r$ we defined

$$\beta_i(k) = \begin{cases} \alpha_{i_1} & \text{if } k = 1, \\
 s_{i_1} \cdots s_{i_{k-1}}(\alpha_{i_k}) & \text{otherwise}. \end{cases}$$

**Corollary 9.3.** For $1 \leq k \leq r$ we have $\dim(M_k) = \beta_1(k)$.

**Proof.** By Corollary 9.2 we know that $\dim(V_k) = \varpi_{ik} - s_{i_1} s_{i_2} \cdots s_{i_k}(\varpi_{ik})$ for each $1 \leq k \leq r$. By the definition of $M_k$ we have

$$\dim(M_k) = \dim(V_k) - \dim(V_{k^-}) = s_{i_1} s_{i_2} \cdots s_{i_{k-1}}(\varpi_{ik}) - s_{i_1} s_{i_2} \cdots s_{i_{k}}(\varpi_{ik}) = s_{i_1} s_{i_2} \cdots s_{i_{k-1}}(\varpi_{ik} - s_{i_{k-1}} s_{i_{k}}(\varpi_{ik})).$$

But

$$s_j(\varpi_{ik}) = \begin{cases} \varpi_{ij} & \text{if } j \neq i_k, \\
 \varpi_{ik} - \alpha_{i_k} & \text{if } j = i_k. \end{cases}$$

It follows that

$$\dim(M_k) = s_{i_1} s_{i_2} \cdots s_{i_{k-1}}(\varpi_{ik} - \varpi_{ik} + s_{i_{k-1}} s_{i_{k}}(\alpha_{i_k})) = s_{i_1} s_{i_2} \cdots s_{i_{k-1}}(\alpha_{i_k}).$$

This finishes the proof.
Corollary 9.4. We have $\Delta_w^+ = \{ \dim(M_1), \ldots, \dim(M_r) \}$.

9.2. Example. Let $Q$ be a quiver with underlying graph

```
1 2 3
/  |
4   
```

Let $w$ be the Weyl group element $s_3s_4s_2s_1s_4$. The set of reduced expressions for $w$ is $R(w) = \{(3, 4, 2, 1, 4), (3, 4, 1, 2, 4)\}$. We have

$\Delta_w^+ = \{ 0 0 0, 1 1 0, 1 0 1, 1 1 1 \}$.

Let $i = (3, 4, 2, 1, 4)$. We get

$V_i = V_1 \oplus \cdots \oplus V_5 = 4 \oplus 1 4 \oplus 4 4 \oplus 2 4 \oplus 1 4 3$.

and

$M_i = M_1 \oplus \cdots \oplus M_5 = 4 \oplus 1 4 \oplus 4 4 \oplus 2 4 \oplus 1 4 3$.

Note that $\text{add}(M_i)$ is neither closed under factor modules nor under submodules. We have

$\mathcal{C}_w = \text{add}(V_1 \oplus 1 4 3)$.

We can think of $\mathcal{C}_w$ as a categorification of a cluster algebra of type $A_1$ with four coefficients.

9.3. Example. Let $Q$ be a quiver with underlying graph $1 \rightarrow 2 \rightarrow 3$ Then $i := (i_1, \ldots, i_1) := (3, 1, 2, 3, 1, 2, 1)$ is a reduced expression of a Weyl group element $w \in W_Q$. The indecomposable direct summands of $V_i$ are

$V_1 = 1$

$V_2 = 2 1$

$V_3 = 2 1 2 1$

$V_4 = 2 1 2 3$

$V_5 = 2 1 2 1 2 1$

$V_6 = 2 1 2 1 3 2 1 2 1 1 2 1 2 1$

$V_7 = 2 1 2 1 1 2 1 3 2 1 3 2 1 2 1 2 1$

Here, the $\Lambda$-modules are represented by their socle filtration. The indecomposable $\mathcal{C}_w$-projective-injective modules are $V_5, V_6$ and $V_7$. The corresponding functions $\varphi_{V_k}$ are given by

$\varphi_{V_1} = D_{\omega_1, s_1(\omega_1)}$

$\varphi_{V_2} = D_{\omega_2, s_1s_2(\omega_2)}$

$\varphi_{V_3} = D_{\omega_1, s_1s_2s_1(\omega_1)}$

$\varphi_{V_4} = D_{\omega_3, s_1s_2s_3(\omega_3)}$

$\varphi_{V_5} = D_{\omega_2, s_1s_2s_3s_2(\omega_2)}$

$\varphi_{V_6} = D_{\omega_1, s_2s_1s_2s_3s_2s_1(\omega_1)}$

$\varphi_{V_7} = D_{\omega_3, s_1s_2s_3s_2s_1s_3(\omega_3)}$

9.4. Example. We continue to discuss the example from Section 3.3.5. Thus $Q$ is a quiver with underlying graph $1 \rightarrow 2 \rightarrow 3 \rightarrow 4$. Note that the Weyl group $W_Q$ is the symmetric group $S_5$, and the generators $s_i$ are the transpositions $(i, i+1)$. The generalized minors become ordinary minors. More precisely, for $w \in S_5$ and $i \in \{1, 2, 3, 4, 5\}$ we have

$\Delta_{\omega_1, w(\omega_1)} = \Delta_{\{1, 2, \ldots, i\}, w(\{1, 2, \ldots, i\})}$.
since we may identify $S_5$ with the group of permutation matrices in $\text{GL}_5$. Here $\Delta_{I,J}$ denotes the minor in $\mathbb{C}[\text{SL}_5]$ with row set $I$ and column set $J$. As in Section 3.5 let $w := s_3s_4s_2s_1s_3s_4s_2s_1$ and $i := (i_8, \ldots, i_1) := (3, 4, 2, 1, 3, 4, 2, 1)$. We get

$$x_1(t) := x_3(t_8)x_4(t_7)x_2(t_6)x_1(t_5)x_3(t_4)x_4(t_3)x_2(t_2)x_1(t_1) =$$

$$= \begin{pmatrix}
1 & t_5 + t_1 & t_5 t_2 & 0 & 0 \\
0 & 1 & t_6 + t_2 & t_6 t_4 & t_6 t_4 t_3 \\
0 & 0 & 1 & t_8 + t_4 & t_8 (t_7 + t_3) + t_4 t_3 \\
0 & 0 & 0 & 1 & t_7 + t_3 \\
0 & 0 & 0 & 0 & 1
\end{pmatrix}.$$  

A straightforward calculation shows:

$$D_{w_1, w_5^{-1}(w_1)} = D_{\{1\}, \{2\}} = t_5 + t_1,$$

$$D_{w_2, w_5^{-1}(w_2)} = D_{\{1, 2\}, \{2, 3\}} = t_6(t_5 + t_1) + t_2 t_1,$$

$$D_{w_4, w_5^{-1}(w_4)} = D_{\{1, 2, 3, 4\}, \{1, 2, 3, 5\}} = t_7 + t_3,$$

$$D_{w_3, w_5^{-1}(w_3)} = D_{\{1, 2, 3\}, \{2, 3, 5\}} = t_8(t_7(t_6(t_5 + t_1) + t_2 t_1) + t_6 t_3(t_5 + t_1) + t_3 t_2 t_1)
+ t_4 t_3 t_2 t_1,$$

$$D_{w_1, w_5^{-1}(w_1)} = D_{\{1\}, \{3\}} = t_5 t_2,$$

$$D_{w_2, w_5^{-1}(w_2)} = D_{\{1, 2\}, \{3, 5\}} = t_6 t_5 t_4 t_3 t_2,$$

$$D_{w_4, w_5^{-1}(w_4)} = D_{\{1, 2, 3, 4\}, \{2, 3, 4, 5\}} = t_7 t_4 t_2 t_1,$$

$$D_{w_3, w_5^{-1}(w_3)} = D_{\{1, 2, 3\}, \{3, 4, 5\}} = t_8 t_7 t_6 t_5 t_4 t_2.$$  

Here the evaluation of the minors is always on $x_1(t)$. Due to the structure of the modules $V_k$ described in Section 3.5 we could also use Proposition 6.1 and calculate directly that

$$\varphi_{V_k}(x_1(t)) = D_{w_{ik}, w_{k}^{-1}(w_{ik})}(x_1(t))$$

for all $1 \leq k \leq 8$.

9.5. **Refined socle and top series.** For any $\Lambda$-module $X \in \mathcal{C}_w$ there exists a unique chain

$$0 = X_r \subseteq \cdots \subseteq X_1 \subseteq X_0 = X$$

of submodules of $X$ such that $X_{k-1}/X_k = \text{soc}_{S_i}(X/X_k)$. This is called the **refined socle series** of type $i$ of $X$. Define

$$s_i(X) := (p_r, \ldots, p_1)$$

where $p_k := \dim(X_{k-1}/X_k)$ for $1 \leq k \leq r$. Similarly, there exists a unique chain

$$0 = Y_r \subseteq \cdots \subseteq Y_1 \subseteq Y_0 = X$$

of submodules of $X$ such that $Y_{k-1}/Y_k = \text{top}_{S_i}(Y_{k-1})$ for all $1 \leq k \leq r$. This is called the **refined top series** of type $i$ of $X$. Define

$$t_i(X) := (q_r, \ldots, q_1)$$

where $q_k := \dim(Y_{k-1}/Y_k)$ for $1 \leq k \leq r$. (For a simple module $S$ and a module $M$ let $\text{top}_S(M)$ be the intersection of all submodules $U$ of $M$ with $M/U \cong S$.)

The existence of refined socle and top series of type $i$ of $X \in \mathcal{C}_w$ comes from the fact that $V_i$ generates the category $\mathcal{C}_w$. It follows directly from the definitions that each module $V_k$ has a refined socle and top series of type $i$. Now one easily checks that this property also holds for factor modules of modules in $\text{add}(V_i)$. 

The uniqueness of refined socle and top series of type \( i \) implies the following result:

**Lemma 9.5.** Let \( i = (i_r, \ldots, i_1) \) be a reduced expression of \( w \), and let \( X \in C_w \). Set \( s := s_i(X) = (p_r, \ldots, p_1) \) and \( t := t_i(X) = (q_r, \ldots, q_1) \). Then the following hold:

(i) We have

\[
F_{i_s, X} \cong \prod_{k=1}^r F(\mathbb{C}^{p_k}) \quad \text{and} \quad F_{i_t, X} \cong \prod_{k=1}^r F(\mathbb{C}^{q_k}).
\]

In particular,

\[
\chi_c(F_{i_s, X}) = \prod_{k=1}^r p_k! \quad \text{and} \quad \chi_c(F_{i_t, X}) = \prod_{k=1}^r q_k!.
\]

(ii) \( F_{i_s, X} \) and \( F_{i_t, X} \) both consist of a single point. In particular, \( \chi_c(F_{i_s, X}) = 1 \) and \( \chi_c(F_{i_t, X}) = 1 \).

Observe that \( (i_k, \ldots, i_t) \) is a reduced expression for the Weyl group element \( w_{k,t} := s_{i_k} s_{i_{k-1}} \cdots s_{i_t} \) for all \( 1 \leq t \leq k \leq r \). Set \( j := (i_r, \ldots, i_2) \). For \( 1 \leq k \leq r \) define

\[
b_k := b_{i,k} := -(s_{i_k} \cdots s_{i_1}(\varpi_{i_r}), \alpha_{i_k}) = (s_{i_k+1} \cdots s_{i_r}(\varpi_{i_r}), \alpha_{i_k}),
\]

and set \( b_1 := (b_r, \ldots, b_1) \).

**Proposition 9.6.** For \( i \) and \( j \) as above, the following hold:

(i) \( \text{top}_{s_i} (V_{j, r-1}) = 0 \);
(ii) \( \text{top}_{s_i} (V_{1, r}) = S_{i_1}^c \);
(iii) \( s_i(V_{1, r}) = t_i(V_{1, r}) = b_1 \).

**Proof.** For \( r = 1 \) the statements are obvious. Thus assume \( r \geq 2 \). Let \( u_{\varpi_{i_r}} \) be a highest weight vector in \( L(\varpi_{i_r}) \). Since \( i = (j, i_1) \) is a reduced expression, we know from Section 7.1 that

\[
e_{i_1}(s_{i_2} \cdots s_{i_r}(u_{\varpi_{i_r}})) = 0.
\]

By Proposition 9.1 we can identify \( s_{i_2} \cdots s_{i_r}(u_{\varpi_{i_r}}) \) with \( \varphi_{V_{j, r-1}} \). We have \( \text{top}_{s_{i_1}} (V_{j, r-1}) \cong S_{i_1}^c \) for some \( c \geq 0 \). Let \( U \) be the unique submodule such that \( V_{j, r-1}/U = \text{top}_{s_{i_1}} (V_{j, r-1}) \).

We get

\[
e_{i_1}^{(c)} \varphi_{V_{j, r-1}} = \varphi_U \neq 0.
\]

But if \( c \geq 1 \), then equation (3) yields \( e_{i_1}^{(c)} \varphi_{V_{j, r-1}} = 0 \), a contradiction. This implies \( c = 0 \).

So we proved (i). To show (ii) we use that \( \varphi_{V_{1, r}} \) can be identified with

\[
\varphi_{V_{j, r-1}}(s_{i_2} \cdots s_{i_r}(u_{\varpi_{i_r}})) = f_{i_1}^{(c)} (s_{i_2} \cdots s_{i_r}(u_{\varpi_{i_r}})) = f_{i_1}^{(c)} (\varphi_{V_{j, r-1}}).
\]

We have \( \text{wt}(s_{i_2} \cdots s_{i_r}(u_{\varpi_{i_r}})) = \text{wt}(s_{i_2} \cdots s_{i_r}(u_{\varpi_{i_r}})) - b_1 \alpha_{i_1} \), see Section 7.1. This implies (ii). Finally, it follows by induction on \( r \) that \( s_i(V_{1, r}) = t_i(V_{1, r}) = b_1 \). This finishes the proof. \( \square \)
9.6. Computation of the Euler characteristics $\chi_c(\mathcal{F}_k, V_k)$. By Proposition 6.11 to evaluate $\varphi_{V_k}$ on $x_{j_1}(t_1) \cdots x_{j_p}(t_p)$, we need to know the Euler characteristic $\chi_c(\mathcal{F}_k, V_k)$ for arbitrary types $k$ of composition series. These Euler characteristics can in turn be calculated via a simple algorithm that we shall now describe.

To this end, it will be convenient to embed $U(n)_{\mathbb{C}^*}^+ = \mathbb{C}[N]$ in the shuffle algebra $F^*$, as explained in [Le, §2.8]. As a $\mathbb{C}$-vector space, $F^*$ has a basis consisting of all words

$$w[k] := w[k_1, k_2, \ldots, k_s] := w_{k_1}w_{k_2} \cdots w_{k_s}, \quad (1 \leq k_1, \ldots, k_s \leq n, \ s \geq 0),$$

in the letters $w_1, \ldots, w_n$. The multiplication in $F^*$ is the classical commutative shuffle product $\mathcal{W}$ of words with unit the empty word $\emptyset$, see e.g. [Re] and [Le, §2.5]. By [Le, Propositions 9 and 10], for any $X \in \text{nil}(\Lambda)$ the image of $\varphi_X$ in this embedding is just the generating function

$$g_X := \sum_k \chi_c(\mathcal{F}_k, X) w[k]$$

of the Euler characteristics $\chi_c(\mathcal{F}_k, X)$ for all types $k$ of composition series. (The Euler characteristic $\chi_c(\mathcal{F}_k, X)$ is equal to the coefficient of $t_1 \cdots t_s$ in $\varphi_X(x_{k_1}(t_1) \cdots x_{k_s}(t_s))$.)

Let $\lambda \in P^+$ and $1 \leq i \leq n$. Define endomorphisms $\rho_\lambda(e_i), \rho_\lambda(f_i)$ of the vector space $F^*$ by

$$\rho_\lambda(e_i)(w[j_1, \ldots, j_k]) := \delta_{i,j_k} w[j_1, \ldots, j_{k-1}],$$

$$\rho_\lambda(f_i)(w[j_1, \ldots, j_k]) := \sum_{l=0}^k (\lambda - \alpha_{j_1} - \cdots - \alpha_{j_l}) (\alpha_i^\vee) w[j_1, \ldots, j_{l-1}, i, j_{l+1}, \ldots, j_k].$$

Proposition 9.7. The formulas above extend to a representation $\rho_\lambda : U(\mathfrak{g}) \to \text{End}_\mathbb{C}(F^*)$ of $U(\mathfrak{g})$. This turns $F^*$ into a $U(\mathfrak{g})$-module. The image of $\mathbb{C}[N]$ in its embedding in $F^*$ is a $U(\mathfrak{g})$-submodule isomorphic to the dual Verma module $M^*_{\text{low}}(\lambda)$, see Section 4.5. In particular the set

$$\{ \rho_\lambda(f_{i_1} \cdots f_{i_s})(\emptyset) \mid 1 \leq i_1, \ldots, i_s \leq n, \ s \geq 0 \}$$

spans the irreducible module $L(\lambda)$, considered as a submodule of $M^*_{\text{low}}(\lambda)$.

The above formulas for $\rho_\lambda(e_i)$ and $\rho_\lambda(f_i)$ can be obtained by specializing $q$ to 1 in the formulas of the proof of [Le, Proposition 50]. We omit the details.

By Proposition 9.1 for $1 \leq k \leq r$ we have

$$\varphi_{V_k} = D_{\omega_{i_k}, u_k^{-1}(\omega_{i_k})}.$$

By Section 7.1 we know that $\varphi_{V_k}$ is obtained by acting on the highest weight vector $u_{\omega_{i_k}}$ of $L(\omega_{i_k})$ with the product $f_{i_1}^{(b_1)} \cdots f_{i_k}^{(b_k)}$ of divided powers of the Chevalley generators, where $b_k = b_{i,k}$ is defined as in Section 9.5. Therefore we have

$$g_{V_k} = \rho_{\omega_{i_k}} \left( f_{i_1}^{(b_1)} \cdots f_{i_k}^{(b_k)} \right)(\emptyset).$$

Hence to calculate the generating function $g_{V_k}$ one only needs to apply $b_1 + \cdots + b_k = \dim(V_k)$ times the above combinatorial formula for $\rho_{\omega_{i_k}}(f_i)$. Thus we have obtained an algorithm for calculating all Euler characteristics $\chi_c(\mathcal{F}_k, V_k)$. 
9.7. Example. We continue the example of Section 9.3. Clearly, we have
\[ gv_1 = \rho_{\omega_1}(f_1)(w[]) = \omega_1(\alpha_1^\vee) w[1] = w[1]. \]
Similarly
\[ gv_2 = \rho_{\omega_2}(f_1^{(2)} f_2)(w[]). \]
Now we calculate successively
\[
\rho_{\omega_2}(f_2)(w[]) = \omega_2(\alpha_2^\vee) w[2] = w[2], \\
\rho_{\omega_2}(f_1)(w[2]) = \omega_2(\alpha_2^\vee) w[1, 2] + (\omega_2 - \alpha_2)(\alpha_1^\vee) w[2, 1] = 2 w[2, 1], \\
\rho_{\omega_2}(f_1)(2 w[2, 1]) = 2(\omega_2(\alpha_1^\vee) w[1, 2, 1] + (\omega_2 - \alpha_2)(\alpha_1^\vee) w[2, 1, 1]) \\
+ (\omega_2 - \alpha_2 - \alpha_1)(\alpha_1^\vee) w[2, 1, 1]) = 4 w[2, 1, 1].
\]
Hence, taking into account that \( f_1^{(2)} = f_1^2 / 2 \), we get
\[ gv_2 = 2 w[2, 1, 1]. \]
Similar applications of formula (4) yield the following results
\[
\begin{align*}
 gv_3 &= \rho_{\omega_1}\left(f_1^{(3)} f_2^{(2)} f_1\right)(w[]) = 4 w[1, 2, 1, 2, 1, 1, 1] + 12 w[1, 2, 2, 1, 1, 1, 1], \\
 gv_4 &= \rho_{\omega_3}\left(f_1^{(2)} f_2 f_3\right)(w[]) = 2 w[3, 2, 1, 1], \\
 gv_5 &= \rho_{\omega_3}\left(f_1^{(4)} f_2^{(3)} f_1^{(2)} f_2 f_3\right)(w[]) \\
 &= 288 w[3, 2, 1, 1, 2, 2, 2, 1, 1, 1, 1] + 144 w[3, 2, 1, 1, 2, 2, 1, 2, 1, 1, 1] \\
+ 96 w[3, 2, 1, 1, 2, 2, 1, 1, 1, 1, 1] + 48 w[3, 2, 1, 1, 2, 2, 1, 2, 1, 1, 1] \\
+ 48 w[3, 2, 1, 1, 2, 2, 1, 1, 1, 1, 1] + 16 w[3, 2, 1, 1, 2, 2, 1, 1, 1, 1, 1] \\
+ 16 w[3, 2, 1, 1, 2, 1, 2, 1, 2, 1, 1] + 16 w[3, 2, 1, 1, 2, 1, 1, 2, 1, 2, 1, 1].
\end{align*}
\]
The generating functions \( gv_5 \) and \( gv_6 \) are too large to be included here. For example \( gv_5 \) is a linear combination of 402 words.

9.8. The modules \( M[b, a] \). For \( 1 \leq k \leq r \) let
\[
\begin{align*}
 k^- &= \max\{0, 1 \leq s \leq k - 1 \mid i_s = i_k\}, \\
 k^+ &= \min\{k + 1 \leq s \leq r, r + 1 \mid i_s = i_k\}, \\
 k_{\min} &= \min\{1 \leq s \leq r \mid i_s = i_k\}, \\
 k_{\max} &= \max\{1 \leq s \leq r \mid i_s = i_k\}.
\end{align*}
\]
Set \( k^{(0)} := k \), and for an integer \( m \) define \( k^{(m-1)} := (k^{(m)})^- \) and \( k^{(m+1)} := (k^{(m)})^+ \). For \( 1 \leq j \leq n \) and \( 1 \leq k \leq r + 1 \) let
\[
k^-(j) := \max\{0, 1 \leq s \leq k - 1 \mid i_s = j\},
\]
and
\[
k[j] := |\{1 \leq s \leq k - 1 \mid i_s = j\}|,
\]
and set \( t_j := (r + 1)[j] \).

For \( 1 \leq a \leq b \leq r \) with \( i_a = i_b \) define \( M[b, a] := V_b / V_a^- \). (For convenience, we define \( V_0 = V_{r+1} = 0 \).) We have a short exact sequence
\[
0 \to M[a^-, b_{\min}] \to M[b, b_{\min}] \to M[b, a] \to 0.
\]
Note that $a_{\text{min}} = b_{\text{min}}$, since we assume $i_a = i_b$. For $1 \leq k \leq r$ we have $M[k, k_{\text{min}}] = V_k$ and $M[k, k] = M_k$. One can visualize a module $M[b, a]$ by

\[
\begin{array}{c}
M_b \\
\vdots \\
M_a
\end{array}
\]

We have

\[V_i = \bigoplus_{k=1}^{r} M[k, k_{\text{min}}].\]

For each $k$ we have a short exact sequence

\[0 \to M[k, k_{\text{min}}] \to M[k_{\text{max}}, k_{\text{min}}] \to M[k_{\text{max}}, k^+] \to 0.
\]

Note that $M[k_{\text{max}}, k_{\text{min}}] = I_{1, i_k}$ is $C_w$-projective-injective. Define

\[T_k := T_{i, k} := \begin{cases} V_k & \text{if } k^+ = r + 1, \\ M[k_{\text{max}}, k^+] & \text{otherwise.} \end{cases}\]

Thus if $k^+ \neq r + 1$, then $\Omega_w^{-1}(V_k) = T_k$. Define $T_i := T_1 \oplus \cdots \oplus T_r$. In other words, we have

\[T_i = \bigoplus_{k=1}^{r} M[k_{\text{max}}, k] = I_w \oplus \Omega_w^{-1}(V_i).
\]

9.9. **Computation of $\dim \text{Hom}_A(V_k, M_s)$.**

**Lemma 9.8.** Let $1 \leq k, s \leq r$.

(i) If $k \leq s$, then we have

\[\dim \text{Hom}_A(V_k, M_s) = \dim \text{Hom}_A(M_k, M_s) = \begin{cases} 0 & \text{if } k < s, \\ 1 & \text{if } k = s. \end{cases}\]

(ii) If $k > s$, then

\[\dim \text{Hom}_A(V_k, M_s) = \begin{cases} \sum_{m \geq 0, k(-m) > s} (M_{k(-m)}, M_s)q & \text{if } i_k \neq i_s, \\ 1 + \sum_{m \geq 0, k(-m) > s} (M_{k(-m)}, M_s)q & \text{if } i_k = i_s. \end{cases}\]

(iii) We have

\[\dim \text{Hom}_A(V_k, V_s) = \dim \text{Hom}_A(V_k, M_s \oplus M_s^{-} \oplus \cdots \oplus M_{s_{\text{min}}}).\]

**Proof.** We have short exact sequences

\[
\begin{align*}
\eta : & \quad 0 \to V_{k} \xrightarrow{i_k} V_{k} \xrightarrow{\pi_k} M_{k} \to 0 \quad \text{and} \quad \\
\psi : & \quad 0 \to V_{s} \xrightarrow{i_s} V_{s} \xrightarrow{\pi_s} M_{s} \to 0.
\end{align*}
\]

First, assume that $k < s$. Then the module $M_k$ is contained in $C_{(i_s, \ldots, i_1)}$ and also in $C_{(i_s-1, \ldots, i_1)}$. Now $V_s$ is $C_{(i_s, \ldots, i_1)}$-projective-injective and $V_s^{-}$ is $C_{(i_s-1, \ldots, i_1)}$-projective-injective. This implies

\[\dim \text{Hom}_A(M_k, V_s^{-}) = \dim \text{Hom}_A(M_k, V_s) \quad \text{and} \quad \dim \text{Ext}_A^{1}(M_k, V_s^{-}) = 0.
\]

Now apply $\text{Hom}_A(M_k, -)$ to the sequence $\psi$ and get $\text{Hom}_A(M_k, M_s) = 0$. Next, apply $\text{Hom}_A(-, M_s)$ to $\eta$. We have $\text{Hom}_A(M_k, M_s) = 0$ and by induction we also get $\text{Hom}_A(V_{k-}, M_s) = 0$. This implies $\text{Hom}_A(V_k, M_s) = 0$.

Next, let $k = s$. We apply $\text{Hom}_A(-, M_k)$ to $\eta$. Since $\text{Hom}_A(V_{k-}, M_k) = 0$, we get $\dim \text{Hom}_A(V_k, M_k) = \dim \text{Hom}_A(M_k, M_k)$. 
Applying $\text{Hom}_\Lambda(V_k, -)$ to $\eta$ gives an exact sequence
\[
0 \to \text{Hom}_\Lambda(V_k, V_{k-}) \xrightarrow{\text{Hom}_\Lambda(V_k, \eta_k)} \text{Hom}_\Lambda(V_k, V_k) \xrightarrow{\text{Hom}_\Lambda(V_k, \pi_k)} \text{Hom}_\Lambda(V_k, M_k) \to 0.
\]
Here we use that $V_{k-}$ is contained in $C_{(i_k, \ldots, i_1)}$ and $V_k$ is $C_{(i_k, \ldots, i_1)}$-projective-injective. Thus every homomorphism $h: V_k \to M_k$ factors through $\pi_k$. In other words, there exists some $g: V_k \to V_k$ such that $\pi_k \circ g = h$. Now $V_k$ is indecomposable, so the endomorphism ring $\text{End}_\Lambda(V_k)$ is local. Therefore $g = \lambda \text{id}_{V_k} + g'$ for some nilpotent endomorphism $g'$ and some $\lambda \in K$. Now we easily see that the image of $g'$ is contained in $\iota_k(V_{k-})$. Thus $h = \lambda \pi_k$.

This implies $\text{dim} \text{Hom}_\Lambda(V_k, M_k) = 1$.

Finally, assume that $k > s$. Then Lemma 2.1 yields
\[
\text{dim Ext}_\Lambda^1(V_k, M_s) = \text{dim Hom}_\Lambda(V_k, M_s) + \text{dim Hom}_\Lambda(M_s, V_k) - (V_k, M_s)_Q
\]
\[
= \text{dim Hom}_\Lambda(V_k, M_s) + \text{dim Hom}_\Lambda(M_s, V_k) - (V_k, M_s)_Q - (M_k, M_s)_Q
\]
\[
= \text{dim Hom}_\Lambda(V_k, M_s) + \text{dim Hom}_\Lambda(M_s, V_k) + \text{dim Ext}_\Lambda^1(V_{k-}, M_s) - \text{dim Hom}_\Lambda(M_s, V_{k-}) - (M_k, M_s)_Q.
\]

Since $s < k$, we have $\text{dim Hom}_\Lambda(M_s, V_{k-}) = \text{dim Hom}_\Lambda(M_s, V_k)$ and $\text{Ext}_\Lambda^1(V_k, M_s) = \text{Ext}_\Lambda^1(V_{k-}, M_s) = 0$. Thus we get
\[
\text{dim Hom}_\Lambda(V_k, M_s) = (M_k, M_s)_Q + \text{dim Hom}_\Lambda(V_{k-}, M_s).
\]

The result follows by induction.

To prove (iii) we just apply $\text{Hom}_\Lambda(V_k, -)$ to the short exact sequence $0 \to V_{s-} \to V_s \to M_s \to 0$, and then use induction. \hfill $\square$

Note that in general we have $\text{dim Hom}_\Lambda(V_k, M_s) \neq \text{dim Hom}_\Lambda(M_k, M_s)$.

\textbf{Corollary 9.9.} For $1 \leq k \leq r$ we have $\text{Ext}_\Lambda^1(M_k, M_k) = 0$.

\textbf{Proof.} Again we use the short exact sequence
\[
\eta : \quad 0 \to V_{k-} \to V_k \to M_k \to 0.
\]

The three modules in this sequence are contained in $C_{(i_k, \ldots, i_1)}$. In particular, $V_k$ is $C_{(i_k, \ldots, i_1)}$-projective-injective. This implies $\text{Ext}_\Lambda^1(V_k, M_k) = 0$. We have $\text{Hom}_\Lambda(V_{k-}, M_k) = 0$ by Lemma 9.8. Thus, applying the functor $\text{Hom}_\Lambda(-, M_k)$ to $\eta$ we get $\text{Ext}_\Lambda^1(M_k, M_k) = 0$. \hfill $\square$

\textbf{Corollary 9.10.} For $1 \leq k \leq r$ with $k^- \neq 0$ we have $\text{dim Ext}_\Lambda^1(M_k, V_{k-}) = 1$.

\textbf{Proof.} Apply $\text{Hom}_\Lambda(M_k, -)$ to the sequence $\eta$ appearing in the proof of Corollary 9.9. \hfill $\square$

\section{The add($M_t$)-stratification of $C_w$}

10.1. \textbf{The stratification.} Let $a = (a_1, \ldots, a_r)$ be a tuple of nonnegative integers, and let $C_{M_{t,a}}$ be the category of all $\Lambda$-modules $X$ such that there exists a chain
\[
0 = X_0 \subseteq X_1 \subseteq \cdots \subseteq X_r = X
\]
of submodules of $X$ with $X_k/X_{k-1} \cong M_k^{a_k}$ for all $1 \leq k \leq r$.

\textbf{Lemma 10.1.} If $X$ is a module in $C_{M_{t,a}}$ and $C_{M_{t,b}}$, then $a = b$. 

Proof. Let \( \mathbf{a} = (a_1, \ldots, a_r) \) and \( \mathbf{b} = (b_1, \ldots, b_r) \). There is a short exact sequence

\[
0 \rightarrow X_{r-1} \rightarrow X \rightarrow M_r^{a_r} \rightarrow 0.
\]

Lemma 9.8 and induction shows that \( \text{Hom}_A(X_{r-1}, M_r) = 0 \). Thus \( \dim \text{Hom}_A(X, M_r) = a_r \). Similarly, we get \( \dim \text{Hom}_A(X, M_r) = b_r \). Thus \( a_r = b_r \), and by induction we get \( a_k = b_k \) for all \( 1 \leq k \leq r \).

Define

\[
C_{M_i} := \bigcup_{a \in \mathbb{N}^r} C_{M_i,a}.
\]

Lemma 10.2. We have \( C_w = C_{M_i} \).

Proof. The category \( C_w \) contains all \( M_k \), and \( C_w \) is closed under extensions. This implies \( C_{M_i} \subseteq C_w \).

Vice versa, assume \( X \in C_w \). By Proposition 2.15 there exists a short exact sequence

\[
\varepsilon : 0 \rightarrow V'' \xrightarrow{f} V' \xrightarrow{g} X \rightarrow 0
\]

with \( V', V'' \in \text{add}(V_i) \) and \( g \) is a minimal right \( \text{add}(V_i) \)-approximation. We call \( \varepsilon \) a minimal \( \text{add}(V_i) \)-resolution of length at most one. Since \( V_r \) is \( C_w \)-projective-injective, by the minimality of \( g \) we know that \( V'' \) does not contain a direct summand isomorphic to \( V_r \).

Let \( U \) be the unique submodule of \( V' \) such that \( V'/U \cong M_r^{a_r} \) with \( a_r \) maximal. Clearly, we have

\[
U \cong V_r^{a_r} \oplus V'/V_r^{a_r}.
\]

By Lemma 9.8 and induction, the image of \( f \) is contained in \( U \). We have \( V'/\text{Im}(f) \cong X \).

Let \( X_{r-1} := g(U) \). We get \( X/X_{r-1} \cong M_r^{a_r} \), and by passing to the restriction maps, we obtain a short exact sequence

\[
0 \rightarrow V'' \xrightarrow{f'} V_r^{a_r} \oplus V'/V_r^{a_r} \rightarrow X_{r-1} \rightarrow 0.
\]

This is an \( \text{add}(V_i) \)-resolution of \( X_{r-1} \). By possibly deleting a direct summand of \( f' \) of the form \( V_r \rightarrow V_{r}^{a_r} \), this yields again a minimal \( \text{add}(V_i) \)-resolution of length at most one of \( X_{r-1} \). The result follows by induction.

For \( X \in C_{M_i,a} \) set

\[
M_i(X) := M_1^{a_1} \oplus \cdots \oplus M_r^{a_r}.
\]

Recall that \( B_i := \text{End}_A(V_i)^{\text{op}} \).

For a \( \Lambda \)-module \( X \in C_w \) we want to compute the dimension vector of the \( B_i \)-module \( \text{Hom}_A(V_i, X) \). The indecomposable projective \( B_i \)-modules are the modules \( \text{Hom}_A(V_i, V_k) \), \( 1 \leq k \leq r \). Thus the entries of the dimension vector \( \text{dim}_{B_i}(\text{Hom}_A(V_i, X)) \) are

\[
\dim \text{Hom}_{B_i}(\text{Hom}_A(V_i, V_k), \text{Hom}_A(V_i, X))
\]

where \( 1 \leq k \leq r \). By Corollaries 2.13 and 2.16 we have

\[
\text{Hom}_{B_i}(\text{Hom}_A(V_i, V_k), \text{Hom}_A(V_i, X)) \cong \text{Hom}_A(V_k, X).
\]

For \( 1 \leq k \leq r \) define

\[
\Delta_k := \text{Hom}_A(V_i, M_k).
\]

(In Section 11 we prove that \( B_i \) is a quasi-hereditary algebra and that the \( \Delta_k \) are the corresponding standard modules.) The following result follows directly from Lemma 9.8.

Lemma 10.3. The dimension vectors \( \text{dim}_{B_i}(\Delta_k) \), \( 1 \leq k \leq r \) are linearly independent.
Lemma 10.4. For all $1 \leq k \leq r$ we have
\[
\dim_{B_l}(\operatorname{Hom}_\Lambda(V_i, V_k)) = \dim_{B_l}(\Delta_k) + \dim_{B_l}(\Delta_{k-}) + \cdots + \dim_{B_l}(\Delta_{k_{\min}}).
\]

Proof. Use the short exact sequence
\[
0 \to V_{k-} \to V_k \to M_k \to 0
\]
and an induction on $k$. \qed

The next result shows that Lemma 10.4 is just a special case of a general fact.

Proposition 10.5. For a $\Lambda$-module $X \in C_w$ and $a = (a_1, \ldots, a_r)$ the following are equivalent:

(i) $X \in C_{M_i,a}$;
(ii) There exists a short exact sequence
\[
0 \to \bigoplus_{k=1}^r V_{k-}^{a_k} \to \bigoplus_{k=1}^r V_k^{a_k} \to X \to 0;
\]
(iii) $\dim_{B_l}(\operatorname{Hom}_\Lambda(V_i, X)) = \dim_{B_l}(\operatorname{Hom}_\Lambda(V_i, M_i(X))) = \sum_{k=1}^r a_k \dim_{B_l}(\Delta_k)$.

Proof. (i) $\implies$ (ii): Assume $X \in C_{M_i,a}$ with $a = (a_1, \ldots, a_r)$. By induction we get the following diagram of morphisms with exact row and columns.

Since $V_r$ is $C_w$-projective-injective, there exists a homomorphism $g'$ such that $\pi \circ g' = g$. Then $[f, g'] : \bigoplus_{k=1}^r V_{k-}^{a_k} \to X$ is an epimorphism. Let $Z := \operatorname{Ker}([f, g'])$. The Snake Lemma yields an exact sequence
\[
\bigoplus_{k=1}^{r-1} V_{k-}^{a_k} \xrightarrow{h'} Z \xrightarrow{h''} V_{r-}^{a_r}.
\]
Clearly, $h''$ is an epimorphism, since $f$ is an epimorphism. For dimension reasons $h'$ is a monomorphism. Thus we get a short exact sequence
\[
0 \to \bigoplus_{k=1}^{r-1} V_{k-}^{a_k} \xrightarrow{h'} Z \xrightarrow{h''} V_{r-}^{a_r} \to 0.
\]
Applying $\operatorname{Hom}_A(V_i, -)$ to this sequence yields an exact sequence of $B_i$-modules with a projective end term. Thus this sequence splits, and we get $Z = \bigoplus_{k=1}^r V_k^{a_k^-}$. So we constructed a short exact sequence

$$
\eta_X: \quad 0 \to \bigoplus_{k=1}^r V_k^{a_k^-} \to \bigoplus_{k=1}^r V_k^{a_k} \to X \to 0.
$$

(ii) $\implies$ (iii): Apply $\operatorname{Hom}_A(V_i, -)$ to the short exact sequence $\eta_X$. Since $V_i$ is rigid, this yields a short exact sequence of $B_i$-modules, and we get

$$
\dim_{B_i}(\operatorname{Hom}_A(V_i, X)) = \dim_{B_i}(\operatorname{Hom}_A(V_i, \bigoplus_{k=1}^r V_k^{a_k^-})) - \dim_{B_i}(\operatorname{Hom}_A(V_i, \bigoplus_{k=1}^r V_k^{a_k})))
$$

$$
= \sum_{k=1}^r a_k (\dim_{B_i}(\operatorname{Hom}_A(V_i, V_k)) - \dim_{B_i}(\operatorname{Hom}_A(V_i, V_k^-)))
$$

$$
= \sum_{k=1}^r a_k \dim_{B_i}(\Delta_k).
$$

This implies (iii).

(iii) $\implies$ (i): Let $X \in C_w$, and assume $\dim_{B_i}(\operatorname{Hom}_A(V_i, X)) = \sum_{k=1}^r a_k \dim_{B_i}(\Delta_k)$. Set $a = (a_1, \ldots, a_r)$. We know that $X \in C_{M_i(a)}$ for some $b = (b_1, \ldots, b_r)$. By the implication (i) $\implies$ (iii) we get $\dim_{B_i}(\operatorname{Hom}_A(V_i, X)) = \sum_{k=1}^r b_k \dim_{B_i}(\Delta_k)$. Since the vectors $\dim_{B_i}(\Delta_1), \ldots, \dim_{B_i}(\Delta_r)$ are linearly independent, we get $a_k = b_k$ for all $k$.  

**Corollary 10.6.** For $X, Y \in C_w$ we have $\dim_{B_i}(\operatorname{Hom}_A(V_i, X)) = \dim_{B_i}(\operatorname{Hom}_A(V_i, Y))$ if and only if $X, Y \in C_{M_i(a)}$ for some $a$.

**Proof.** By Lemma 10.3 the dimension vectors $\dim_{B_i}(\Delta_k)$ are linearly independent. Now use Proposition 10.5.

A short exact sequence $\eta: 0 \to X \to Y \to Z \to 0$ of $A$-modules is called $M_i$-split if $M_i(X) \oplus M_i(Z) \cong M_i(Y)$. Recall that $F_{V_i} := \operatorname{Hom}_A(V_i, -)$.

**Corollary 10.7.** For a short exact sequence $\eta: 0 \to X \to Y \to Z \to 0$ of $A$-modules in $C_w$ the following are equivalent:

(i) $\eta$ is $F_{V_i}$-exact;

(ii) $\eta$ is $M_i$-split.

**Proof.** Clearly, $\eta$ is $F_{V_i}$-exact if and only if

$$
\dim_{B_i}(\operatorname{Hom}_A(V_i, X)) + \dim_{B_i}(\operatorname{Hom}_A(V_i, Z)) = \dim_{B_i}(\operatorname{Hom}_A(V_i, Y))
$$

By Proposition 10.5 this happens if and only if $M_i(X) \oplus M_i(Z) \cong M_i(Y)$.

**10.2. Example.** Let $Q$ be a quiver with underlying graph

$$
1 \longrightarrow 2 \longrightarrow 3
$$

and let $w_0$ be the longest Weyl group element in $W_Q$. Thus we have $C_{w_0} = \operatorname{mod}(A)$. The short exact sequences

$$
\eta': 0 \to 2 \to 1 \oplus 3 \to 1 \oplus 2 \to 3 \to 0 \quad \text{and} \quad \eta'': 0 \to 1 \oplus 2 \to 1 \oplus 2 \to 3 \to 2 \to 0
$$
are exchange sequences in \( \text{mod}(\Lambda) \). Let \( i = (1, 2, 1, 3, 2, 1) \) and \( j = (2, 1, 2, 3, 2, 1) \) be reduced expressions of \( w_0 \). We get

\[
M_i = 1 \oplus 1_2 \oplus 1_3 \oplus 2_3 \oplus 2 \oplus 3 \oplus 2 \\
M_j = 1 \oplus 1_2 \oplus 1_3 \oplus 3 \oplus 2_3 \oplus 2.
\]

Now one easily observes that \( \eta' \) is \( M_i \)-split and not \( M_j \)-split, and \( \eta'' \) is \( M_j \)-split but not \( M_i \)-split.

11. Quasi-hereditary algebras associated to reduced expressions

11.1. Quasi-hereditary algebras. Let \( A \) be a finite-dimensional algebra. By \( P_1, \ldots, P_r \) and \( Q_1, \ldots, Q_r \) and \( S_1, \ldots, S_r \) we denote the indecomposable projective, indecomposable injective and simple \( A \)-modules, respectively, where \( S_i = \text{top}(P_i) = \text{soc}(Q_i) \).

For a class \( U \) of \( A \)-modules let \( F(U) \) be the class of all \( A \)-modules \( X \) which have a filtration

\[
0 = X_0 \subseteq X_1 \subseteq \cdots \subseteq X_t = X
\]

of submodules such that all factors \( X_j/X_{j-1} \) belong to \( U \) for all \( 1 \leq j \leq t \). Such a filtration is called a \( U \)-filtration of \( X \). We call these modules the \( U \)-filtered modules.

Fix a bijective map \( \omega : \{S_1, \ldots, S_r\} \rightarrow \{1, \ldots, r\} \). Let \( \Delta_i \) be the largest factor module of \( P_i \) such that \( [\Delta_i : S_j] = 0 \) for all \( j \) with \( \omega(S_j) > \omega(S_i) \), and set

\[
\Delta = \{\Delta_1, \ldots, \Delta_r\}.
\]

The modules \( \Delta_i \) are called standard modules. The algebra \( A \) is called quasi-hereditary if \( \text{End}_A(\Delta_i) \cong K \) for all \( i \), and if \( _AA \) belongs to \( F(\Delta) \). Quasi-hereditary algebras first occurred in Cline, Parshall and Scott’s [CPS] study of highest weight categories.

Note that the definition of a quasi-hereditary algebra depends on the chosen ordering of the simple modules. If we reorder them, it could happen that our algebra is no longer quasi-hereditary.

Now assume \( A \) is a quasi-hereditary algebra, and let \( F(\Delta) \) be the subcategory of \( \Delta \)-filtered \( A \)-modules. For \( X \in F(\Delta) \) let \( [X : \Delta_i] \) be the number of times that \( \Delta_i \) occurs as a factor in a \( \Delta \)-filtration of \( X \). Then

\[
\text{dim}_\Delta(X) = ([X : \Delta_1], \ldots, [X : \Delta_r]) \in \mathbb{N}^r
\]

is the \( \Delta \)-dimension vector of \( X \). Let \( \nabla_i \) be the largest submodule of \( Q_i \) such that \( [\nabla_i : S_j] = 0 \) for all \( j \) with \( \omega(S_j) > \omega(S_i) \), and let

\[
\nabla = \{\nabla_1, \ldots, \nabla_r\}.
\]

The modules \( \nabla_i \) are called costandard modules. The following results (and the missing definitions) can be found in [Ri2] [Ri3]:

(i) There is a unique (up to isomorphism) basic tilting module \( T(\Delta \cap \nabla) \) over \( A \) such that

\[
\text{add}(T(\Delta \cap \nabla)) = F(\Delta) \cap F(\nabla).
\]

(ii) \( F(\Delta) \) is closed under extensions and under direct summands.

(iii) \( [P_i : \Delta_j] = [\nabla_j : S_i] \) for all \( 1 \leq i, j \leq r \).

(iv) If \( X \in F(\Delta) \), then \( [X : \Delta_i] = \dim \text{Hom}_A(X, \nabla_i) \) for all \( i \).

(v) \( \text{Hom}_A(\Delta_i, \Delta_j) = 0 \) for all \( i, j \) with \( \omega(S_i) > \omega(S_j) \).

(vi) \( \text{Ext}_A^1(\Delta_i, \Delta_j) = 0 \) for all \( i, j \) with \( \omega(S_i) \geq \omega(S_j) \).

(vii) The \( F(\Delta) \)-projective modules are the projective \( A \)-modules. The \( F(\nabla) \)-injective modules are the injective \( A \)-modules.
Theorem 11.1. The original proof of the adaptable case. Later the statement was generalized to arbitrary Weyl group elements by Iyama. Define
\[ \omega \]
and set
\[ B = \text{indecomposable} \]
holds:
11.2. The algebra \( B \) is quasi-hereditary. As before, let \( V_1 = V_1 \oplus \cdots \oplus V_r \) and \( M_1 = M_1 \oplus \cdots \oplus M_r \). Set \( B_i := \text{End}_A(V_i)^{\text{op}} \). For \( 1 \leq k \leq r \) let \( S(k) \) be the (simple) top of the indecomposable \( B_i \)-modules \( P_k := \text{Hom}_A(V_i, V_k) \). As before, define \( \Delta_k := \text{Hom}_A(V_i, M_k) \), and set
\[ \Delta := \{ \Delta_1, \ldots, \Delta_r \}. \]
Define \( \omega : \{S(1), \ldots, S(r)\} \to \{1, \ldots, n\} \) by \( \omega(S(k)) := r - k + 1 \).

The following theorem was first proved in [GLS7, Section 16] for adaptable Weyl group elements. Later the statement was generalized to arbitrary Weyl group elements by Iyama and Reiten [IR]. Here we present a proof for the general case, which is very similar to our original proof of the adaptable case.

Theorem 11.1. Let \( \mathbf{i} \) be a reduced expression of a Weyl group element \( w \). The following hold:

(i) The algebra \( B_1 = \text{End}_A(V_i)^{\text{op}} \) is strongly quasi-hereditary and \( \Delta \)-serial with standard modules \( \Delta = \{ \Delta_1, \ldots, \Delta_r \} \);
(ii) The functor \( \text{Hom}_A(V_i, -) \) yields an equivalence of categories \( F_i : C_w \to \mathcal{F}(\Delta) \);
(iii) \( T(\Delta \cap \nabla) = \text{Hom}_A(V_i, T_i) \).

Proof. (i): We know that for each \( 1 \leq k \leq r \) there is a short exact sequence
\[ \eta : 0 \to V_{k-1} \to V_k \to M_k \to 0. \]
We apply the functor \( \text{Hom}_A(V_i, -) \) to this sequence and obtain a short exact sequence
\[ 0 \to \text{Hom}_A(V_i, V_{k-1}) \to P_k \to \Delta_k \to 0. \]
of $B_1$-modules. Let $\omega(S(j)) \geq \omega(S(k))$, and let $F \colon \text{Hom}_\Lambda(V_i, V_j) \to \Delta_k$ be a homomorphism of $B_1$-modules. Since $\text{Hom}_\Lambda(V_i, V_j)$ is a projective $B_1$-module, there is a homomorphism $G : \text{Hom}_\Lambda(V_i, V_j) \to P_k$ such that $H \circ G = F$. There exists a $\Lambda$-module homomorphism $g : V_j \to V_k$ such that $G = \text{Hom}_\Lambda(V_i, g)$. Assume $\omega(S(j)) > \omega(S(k))$. Since $j < k$, we know that $\text{Im}(g) \subseteq t_k(V_k)$. Thus $\text{Im}(G) \subseteq \text{Im}(\text{Hom}_\Lambda(V_i, t_k)) = \text{Ker}(H)$. But this implies $F = 0$. Therefore we have $[\Delta_k : S(j)] = 0$. Next, we consider the case $\omega(S(j)) = \omega(S(k))$. The endomorphism ring $\text{End}_\Lambda(V_k)$ is local, and we work over an algebraically closed field. Thus $g = \text{Id}_{V_k} + g'$ with $g'$ nilpotent and $\lambda \in K$. We have $\text{soc}(V_k) \subseteq \text{Ker}(g')$. This implies $\text{Im}(g') \subseteq t_k(V_k^-)$. Thus $F = H \circ G = H \circ \text{Hom}_\Lambda(V_i, \text{Id}_{V_k})$. In other words, $\text{Hom}_{B_1}(P_k, \Delta_k)$ is 1-dimensional. This finishes the proof of (i).

(ii): For $X, Z \in C_w$ we have a functorial isomorphism

$$\text{Ext}^1_{F_1}(X, Z) \to \text{Ext}^1_{B_1}(\text{Hom}_\Lambda(V_i, X), \text{Hom}_\Lambda(V_i, Z)).$$

Thus the image of the functor

$$\text{Hom}_\Lambda(V_i, -) : C_w \to \text{mod}(B_1)$$

is extension closed. Clearly, for all $1 \leq k \leq r$ the standard module $\Delta_k$ is in $\text{Hom}_\Lambda(V_i, C_w)$. It follows that $\mathcal{F}(\Delta) \subseteq \text{Hom}_\Lambda(V_i, C_w)$.

Now let $X \in C_w$. By Lemma 10.2 we know that $X \in C_{M_i, a}$ for some $a = (a_1, \ldots, a_r)$. Thus there is a short exact sequence

$$\eta : 0 \to X_{r-1} \to X \to M^a_r \to 0.$$

We claim that $\eta$ is $F_1$-exact: Clearly, $\eta$ is $F_{V_r}$-exact, since $V_r$ is $C_w$-projective-injective and $X_{r-1} \in C_w$. Since $\text{Hom}_\Lambda(V_k, M_r) = 0$ for all $k < r$, it follows that $\eta$ is also $F_{V_k}$-exact for all such $k$. Clearly, $\text{Hom}_\Lambda(V_i, M^a_r)$ is contained in $\mathcal{F}(\Delta)$. By induction also $\text{Hom}_\Lambda(V_i, X_{r-1})$ is in $\mathcal{F}(\Delta)$. Since $\mathcal{F}(\Delta)$ is closed under extensions, and since $\eta$ is $F_1$-exact, we get that $\text{Hom}_\Lambda(V_i, X)$ is in $\mathcal{F}(\Delta)$. So we proved that $\mathcal{F}(\Delta) = \text{Hom}_\Lambda(V_i, C_w)$. Now Corollary 2.13 and Lemma 2.16 show that the restriction functor $F_1 : C_w \to \mathcal{F}(\Delta)$ is an equivalence of categories.

(iii): It is enough to show that $\text{Ext}^1_\Lambda(\Delta_k, T_i) = 0$ for all $1 \leq k \leq r$, see Section 11.1. Recall that all indecomposable direct summands of $T_i$ are of the form $M[s_{\max}, s]$ where $1 \leq s \leq r$. We fix such an $s$.

For each $1 \leq k \leq r$ there is a short exact sequence

$$\eta : 0 \to M[k^-, k_{\min}] \to M[k, k_{\min}] \to M_k \to 0.$$

Applying $\text{Hom}_\Lambda(V_i, -)$ yields a projective resolution

$$0 \to \text{Hom}_\Lambda(V_i, M[k^-, k_{\min}]) \to \text{Hom}_\Lambda(V_i, M[k, k_{\min}]) \to \text{Hom}_\Lambda(V_i, M_k) \to 0$$

of $B_1$-modules.

If $k \leq s$, then $\text{Hom}_\Lambda(M[k^-, k_{\min}], M[s_{\max}, s]) = 0$. Since $F_1$ is an equivalence, we get

$$\text{Hom}_{B_1}(\text{Hom}_\Lambda(V_i, M[k^-, k_{\min}]), \text{Hom}_\Lambda(V_i, M[s_{\max}, s])) = 0.$$

This implies $\text{Ext}^1_{B_1}(\Delta_k, \text{Hom}_\Lambda(V_i, M[s_{\max}, s])) = 0$.

Next, assume that $k > s$. We have a short exact sequence

$$\psi : 0 \to M[s^-, s_{\min}] \to M[s_{\max}, s_{\min}] \to M[s_{\max}, s] \to 0.$$

Applying $\text{Hom}_\Lambda(-, M_k)$ yields $\text{Ext}^1_\Lambda(M[s_{\max}, s], M_k) = 0$. Thus $\text{Ext}^1_\Lambda(M_k, M[s_{\max}, s]) = 0$. This implies

$$\text{Ext}^1_{F_1}(M_k, M[s_{\max}, s]) = \text{Ext}^1_{B_1}(\Delta_k, \text{Hom}_\Lambda(V_i, M[s_{\max}, s])) = 0.$$
Here we used that Ext\(^1_\Lambda(M[s_{\text{max}}, s_{\text{min}}], M_k) = 0\) (since \(M[s_{\text{max}}, s_{\text{min}}]\) is \(C_w\)-projective-injective), and Hom\(\Lambda(M[s^-, s_{\text{min}}], M_k) = 0\) by Lemma 9.8. This finishes the proof of (iii). □

**Corollary 11.2.** The modules Hom\(\Lambda(V_i, I_{i,j})\), \(1 \leq j \leq n\) are the indecomposable \(\mathcal{F}(\Delta)\)-projective-injectives modules.

**Proof.** This follows from Theorem 11.1 (iii) and Section 11.1. □

Each \(\Delta\)-filtration of the indecomposable projective \(B_i\)-module Hom\(\Lambda(V_i, V_k)\) looks as follows:

\[
\begin{array}{c}
\Delta_k \\
\Delta_{k-1} \\
\vdots \\
\Delta_{k_{\text{min}}}
\end{array}
\]

(We just displayed the factors of the (unique) \(\Delta\)-filtration of Hom\(\Lambda(V_i, V_k)\).)

We can now reformulate parts of Proposition 10.5 as follows:

**Proposition 11.3.** For a \(\Lambda\)-module \(X \in C_w\) and \(a = (a_1, \ldots, a_r)\) the following are equivalent:

1. \(X \in C_{M_i, a}\);
2. dim\(\Lambda(F_i(X)) = (a_1, \ldots, a_r)\).

**Proof.** Since \(\Delta_k = \text{Hom}_\Lambda(V_i, M_k)\), it is clear that (iii) in Proposition 10.5 and (2) are equivalent. □

We know that \(B_i\) is an algebra of finite global dimension. Thus one can define the Ringel form

\[
\langle X, Y \rangle_{B_i} := \langle \text{dim}(X), \text{dim}(Y) \rangle_{B_i} := \sum_{j \geq 0} (-1)^j \text{dim Ext}^j_{B_i}(X, Y).
\]

The next lemma gives the values of \(\langle -, - \rangle_{B_i}\) applied to standard modules.

**Lemma 11.4.** For \(1 \leq k, s \leq r\) we have

\[
\langle \Delta_k, \Delta_s \rangle_{B_i} = \dim \text{Hom}_{B_i}(\Delta_k, \Delta_s) - \dim \text{Ext}^1_{B_i}(\Delta_k, \Delta_s) = \begin{cases} 0 & \text{if } k < s, \\ 1 & \text{if } k = s, \\ (M_k, M_s)_Q & \text{if } k > s. \end{cases}
\]

**Proof.** As before, for \(1 \leq t \leq r\) we set \(P_t := \text{Hom}_\Lambda(V_i, V_t)\) and \(\Delta_t := \text{Hom}_\Lambda(V_i, M_t)\). We know that proj.\(\dim(\Delta_t) \leq 1\) for all \(t\). Thus

\[
\langle \Delta_k, \Delta_s \rangle_{B_i} = \dim \text{Hom}_{B_i}(\Delta_k, \Delta_s) - \dim \text{Ext}^1_{B_i}(\Delta_k, \Delta_s).
\]

The cases \(k < s\) and \(k = s\) are clear, see Section 11.1. Thus, assume \(k > s\). The short exact sequence

\[
0 \to V_k^- \to V_k \to M_k \to 0
\]
yields a projective resolution

\[
0 \to P_k^- \to P_k \to \Delta_k \to 0
\]
of \(\Delta_k\). We apply Hom\(\Lambda(-, M_s)\) and obtain an exact sequence

\[
0 \to \text{Hom}_{B_i}(\Delta_k, \Delta_s) \to \text{Hom}_{B_i}(P_k, \Delta_s) \to \text{Hom}_{B_i}(P_k^-, \Delta_s) \to \text{Ext}^1_{B_i}(\Delta_k, \Delta_s) \to 0.
\]
This implies
\[
\langle \Delta_k, \Delta_s \rangle_{B_l} = \dim \text{Hom}_{B_l}(P_k, \Delta_s) - \dim \text{Hom}_{B_l}(P_{k-}, \Delta_s)
= \dim \text{Hom}_\Lambda(V_k, M_s) - \dim \text{Hom}_\Lambda(V_{k-}, M_s)
= (M_k, M_s)_Q.
\]
For the third equality we use Lemma 9.8. \hfill \Box

11.3. Example. For an arbitrary $C_w$-maximal rigid $\Lambda$-module $T$, it seems to be difficult to determine when $\text{End}_\Lambda(T)^{\text{op}}$ is quasi-hereditary and when not.

Even if $Q$ is a quiver with underlying graph

\[
1 \to 2 \to 3
\]

there are maximal rigid modules whose endomorphism algebra is not quasi-hereditary:

Let $w = w_0$ be the longest Weyl group element in $W_Q$. Let $T$ be the $C_w$-maximal rigid $\Lambda$-module
\[
2 \oplus 3 \oplus 2 \oplus 1 \oplus 2 \oplus 1 \oplus 2 \oplus 3 \oplus 1 \oplus 2 \oplus 3.
\]

The quiver of $\text{End}_\Lambda(T)^{\text{op}}$ looks as follows:

\[
\begin{array}{c}
2 \quad 3 \\
\downarrow \\
\begin{array}{c}
1 \\
2 \\
3
\end{array}
\end{array}
\quad
\begin{array}{c}
2 \quad 3 \\
\downarrow \\
\begin{array}{c}
1 \\
2 \\
3
\end{array}
\end{array}
\quad
\begin{array}{c}
2 \\
\downarrow \\
\begin{array}{c}
1 \\
2 \\
3
\end{array}
\end{array}
\]

It is not difficult to show that $\text{End}_\Lambda(T)^{\text{op}}$ is not a quasi-hereditary algebra.

12. Mutations of clusters via dimension vectors

12.1. Dimension vectors of rigid modules. Let $A$ be a finite-dimensional $K$-algebra. For $m \geq 0$ let $A^m$ be the free $A$-module of rank $m$. By $\text{mod}(A, m)$ we denote the affine variety of $m$-dimensional $A$-modules. (One can define $\text{mod}(A, m)$ as the variety of $K$-algebra homomorphisms $A \to M_m(K)$.) If $U$ is a submodule of $A^m$ such that $A^m/U$ is $m$-dimensional, then the Richmond stratum $S(U, A^m)$ is the subset of $\text{mod}(A, m)$ consisting of the modules $X$ such that there exists a short exact sequence
\[
0 \to U \to A^m \to X \to 0,
\]
see [Rm]. A more general situation was studied by Bongartz [Bo].

Theorem 12.1 ([Rm Theorem 1]). The Richmond stratum $S(U, A^m)$ is a smooth, irreducible, locally closed subset of $\text{mod}(A, m)$, and
\[
\dim S(U, A^m) = \dim \text{Hom}(U, A^m) - \dim \text{End}_A(U).
\]

Proposition 12.2. Assume that $\text{gl.dim}(A) < \infty$. Let $M$ and $N$ be rigid $A$-modules of projective dimension at most one. If $\dim(M) = \dim(N)$, then $M \cong N$.

Proof. Let $m$ be the $K$-dimension of $M$ and $N$. Thus, there are projective resolutions
\[
0 \to P \to A^m \to M \to 0 \quad \text{and} \quad 0 \to P' \to A^m \to N \to 0
\]
of $M$ and $N$, respectively. Here we used that the projective dimensions of $M$ and $N$ are at most one. Since $\dim(M) = \dim(N)$, we get $\dim(P) = \dim(P')$. Since $A$ is a finite-dimensional algebra of finite global dimension, its Cartan matrix is invertible. In other
words, the dimension vectors of the indecomposable projective \( A \)-modules are linearly independent. Thus we get \( P \cong P' \).

Since \( M \) and \( N \) are rigid, their \( \text{GL}_m(K) \)-orbits are open in \( \text{mod}(A,m) \). In particular, these orbits are open in the Richmond stratum \( S(P,A^m) \). But \( S(P,A^m) \) is irreducible, and therefore it can contain at most one open orbit. It follows that \( M \cong N \). \( \square \)

Now, let \( C_w = \text{Fac}(V_i) \) be defined as before, and let \( T = T_1 \oplus \cdots \oplus T_r \) be a fixed basic \( C_w \)-maximal rigid module and set \( B := \text{End}_A(T)^{op} \).

**Corollary 12.3.** Let \( X \) and \( Y \) be indecomposable rigid modules in \( C_w \). If
\[
\dim_B(\text{Hom}_A(T,X)) = \dim_B(\text{Hom}_A(T,Y)),
\]
then \( X \cong Y \).

**Proof.** Use Corollary 2.17 and Proposition 2.19(vi), and then apply Proposition 12.2 \( \square \)

### 12.2. Mutations via dimension vectors

We now explain how to calculate mutations of clusters via dimension vectors. We start with some notation: For \( d = (d_1, \ldots, d_r) \) and \( f = (f_1, \ldots, f_r) \) in \( \mathbb{Z}^r \) define
\[
\max\{d, f\} := (h_1, \ldots, h_r)
\]
where \( h_s = \max\{d_s, f_s\} \) for \( 1 \leq s \leq r \). Set \( \text{Max}\{d, f\} := d \) if \( d_s \geq f_s \) for all \( s \). In this case, we write \( d \geq f \). Of course, \( \text{Max}\{d, f\} = d \) implies \( \max\{d, f\} = d \). By \(|d|\) we denote the sum of the entries of \( d \).

Let \( \Gamma \) be a quiver without loops and without 2-cycles and with vertices \( 1, \ldots, r \). Some of these vertices can be considered as *frozen vertices*, i.e. one cannot perform a mutation at these vertices.

Now replace each vertex \( s \) of \( \Gamma \) by some \( d_s \in \mathbb{Z}^r \). Thus we obtain a new quiver \( \Gamma' \) whose vertices are elements in \( \mathbb{Z}^r \).

For \( k \) not a frozen vertex, define the mutation \( \mu_{d_k}(\Gamma') \) of \( \Gamma' \) at the vertex \( d_k \) in two steps:

1. Replace the vertex \( d_k \) of \( \Gamma' \) by
\[
d_k^* := -d_k + \max \left\{ \sum_{d_i \to d_k} d_i, \sum_{d_i \to d_j} d_j \right\}
\]
where the sums are taken over all arrows in \( \Gamma' \) which start, respectively end in the vertex \( d_k \);

2. Change the arrows of \( \Gamma' \) following Fomin and Zelevinsky’s quiver mutation rule for the vertex \( d_k \).

Thus starting with \( \Gamma' \) we can use iterated mutation and obtain quivers whose vertices are elements in \( \mathbb{Z}^r \).

For example, if for each \( s \) we choose \( d_s = -e_s \), where \( e_s \) is the \( s \)th canonical basis vector of \( \mathbb{Z}^r \), then the resulting vertices (i.e. elements in \( \mathbb{Z}^r \)) are the denominator vectors of the cluster variables of the cluster algebra \( A(B(\Gamma)^{\circ}) \) associated to \( \Gamma \), compare with [FZ5, Section 7, Equation (7.7)]. (The variables attached to the frozen vertices serve as (non-invertible) coefficients. To obtain the denominator vectors as defined in [FZ5] one has to
ignore the entries corresponding to these \( n \) coefficients.) It is an open problem, if these denominator vectors actually parametrize the cluster variables of \( \mathcal{A}(B(\Gamma)^\circ) \).

We will show that for an appropriate choice of \( \Gamma \) and of the initial vectors \( d_a \), the quivers obtained by iterated mutation of \( \Gamma' \) are in bijection with the seeds and clusters of \( \mathcal{A}(B(\Gamma)^\circ) \). All resulting vertices (including the \( d_a \)) will be elements in \( \mathbb{N}^r \), and we will show that for our particular choice of initial vectors, we can use “Max” instead of “max” in the formula above. (This holds for all iterated mutations.)

For the rest of this section let \( T = T_1 \oplus \cdots \oplus T_r \) be a basic \( C_w \)-maximal rigid \( \Lambda \)-module, and set \( B := \text{End}_\Lambda(T)^{\text{op}} \).

**Proposition 12.4.** Let \( R = R_1 \oplus \cdots \oplus T_r \) be a basic \( C_w \)-maximal rigid \( \Lambda \)-module. Let

\[
\eta': 0 \to R_k \xrightarrow{f_k} R_k' \xrightarrow{g_k} R_k^* \to 0 \quad \text{and} \quad \eta'': 0 \to R_k^* \xrightarrow{f_k''} R_k' \xrightarrow{g_k''} R_k \to 0
\]

be the two exchange sequences associated to an indecomposable direct summand \( R_k \) of \( R \) which is not \( C_w \)-projective-injective. Then \( \dim \text{Hom}_\Lambda(T, R') \neq \dim \text{Hom}_\Lambda(T, R'') \), and we have

\[
\dim_B(\text{Hom}_\Lambda(T, R_k)) + \dim_B(\text{Hom}_\Lambda(T, R_k^*)) = \max\{\dim_B(\text{Hom}_\Lambda(T, R')), \dim_B(\text{Hom}_\Lambda(T, R''))\}.
\]

Furthermore, the following are equivalent:

(i) \( \eta' \) is \( F_T \)-exact;

(ii) \( \dim \text{Hom}_\Lambda(T, R') > \dim \text{Hom}_\Lambda(T, R'') \);

(iii) \( \dim_B(\text{Hom}_\Lambda(T, R')) \geq \dim_B(\text{Hom}_\Lambda(T, R'')) \).

**Proof.** By Corollary \([2,18]\) we know that \( \text{Hom}_\Lambda(T, R) \) is a classical tilting module over \( B \). Thus we can apply \([Ha2]\) Lemma 2.2] and assume without loss of generality that

\[
\text{Ext}_B^1(\text{Hom}_\Lambda(T, R_k), \text{Hom}_\Lambda(T, R_k^*)) = 0.
\]

By Proposition \([2,12]\)

\[
1 = \dim \text{Ext}_A^1(R_k^*, R_k) \geq \dim \text{Ext}_B^1(R_k^*, R_k) = \dim \text{Ext}_B^1(\text{Hom}_\Lambda(T, R_k^*), \text{Hom}_\Lambda(T, R_k)) > 0.
\]

This implies \( \text{Ext}_A^1(R_k^*, R_k) = \text{Ext}_B^1(R_k^*, R_k) \). Thus \( \eta' \) is \( F_T \)-exact, and

\[
\eta: 0 \to \text{Hom}_\Lambda(T, R_k) \xrightarrow{\text{Hom}_\Lambda(T, f')} \text{Hom}_\Lambda(T, R'') \xrightarrow{\text{Hom}_\Lambda(T, g'')} \text{Hom}_\Lambda(T, R_k^*) \to 0
\]

is a (non-split) short exact sequence. If we apply \( \text{Hom}_\Lambda(T, -) \) to \( \eta'' \), we obtain an exact sequence

\[
0 \to \text{Hom}_\Lambda(T, R_k') \xrightarrow{\text{Hom}_\Lambda(T, f'')} \text{Hom}_\Lambda(T, R''') \xrightarrow{\text{Hom}_\Lambda(T, g''')} \text{Hom}_\Lambda(T, R_k).
\]

Now \( \text{Hom}_\Lambda(T, g''') \) cannot be an epimorphism, since that would yield a non-split extension and we know that \( \text{Ext}_B^1(\text{Hom}_\Lambda(T, R_k), \text{Hom}_\Lambda(T, R_k^*)) = 0 \). Thus for dimension reasons we get \( \dim \text{Hom}_\Lambda(T, R') > \dim \text{Hom}_\Lambda(T, R'') \). Using the functors \( \text{Hom}_B(P, -) \) where \( P \) runs through the indecomposable projective \( B \)-modules, it also follows that \( \dim_B(\text{Hom}_\Lambda(T, R')) > \dim_B(\text{Hom}_\Lambda(T, R'')) \). Finally, the formula for dimension vectors follows from the exactness of \( \eta \).

Proposition \([12,4]\) yields an easy combinatorial rule for the mutation of \( C_w \)-maximal rigid modules. Let \( R = R_1 \oplus \cdots \oplus R_r \) be a basic \( C_w \)-maximal rigid \( \Lambda \)-module. Without loss of
generality we assume that $R_{r-n+1}, \ldots, R_r$ are $C_w$-projective-injective. For $1 \leq s \leq r$ let $d_s := \dim_B(\text{Hom}_A(T, R_s))$.

As before, let $\Gamma_R$ be the quiver of $\text{End}_A(R)^{\text{op}}$. The vertices of $\Gamma_R$ are labeled by the modules $R_s$. For each $s$ we replace the vertex labeled by $R_s$ by the dimension vector $d_s$. The resulting quiver is denoted by $\Gamma'_R$.

For $1 \leq k \leq r-n$ let

$$0 \to R_k \to R' \to R_k^* \to 0 \quad \text{and} \quad 0 \to R_k^* \to R'' \to R_k \to 0$$

be the two resulting exchange sequences. We can now easily compute the dimension vector of the $\text{End}_A(T)^{\text{op}}$-module $\text{Hom}_A(T, R_k^*)$, namely Proposition 12.4 yields that

$$d_k^* := \dim_B(\text{Hom}_A(T, R_k^*)) = \begin{cases} -d_k + \sum_{d_i \to d_k} d_i & \text{if } \sum_{d_i \to d_k} |d_i| > \sum_{d_k \to d_j} |d_j|, \\ -d_k + \sum_{d_k \to d_j} d_j & \text{otherwise}, \end{cases}$$

where the sums are taken over all arrows in $\Gamma'_R$ which start, respectively end in the vertex $d_k$. More precisely, we have

$$(5) \quad d_k^* = -d_k + \max \left\{ \sum_{d_i \to d_k} d_i, \sum_{d_k \to d_j} d_j \right\}$$

and we know that

$$(6) \quad \max \left\{ \sum_{d_i \to d_k} d_i, \sum_{d_k \to d_j} d_j \right\} = \text{Max} \left\{ \sum_{d_i \to d_k} d_i, \sum_{d_k \to d_j} d_j \right\}.$$

**Remark 12.5.** Let $T = T_1 \oplus \cdots \oplus T_r$ be a basic $C_w$-maximal rigid module, and let $B(T) := (\langle S_i, S_j \rangle)_{1 \leq i, j \leq r}$ be the matrix of the Ringel form of the algebra $B := \text{End}_A(T)^{\text{op}}$. Let $X$ be a $T$-reachable $\Lambda$-module, see Section 3.1. Set $d := \dim_B(\text{Hom}_A(T, X)) \in \mathbb{N}^r$. Define

$$\bar{g}_T(X) := d \cdot B(T),$$

where $d$ is considered as a row vector. As explained in [FK] Section 4] the entries of $\bar{g}_T(X)$, which correspond to the non-$C_w$-projective-injective direct summands $T_k$ of $T$ form precisely the $g$-vector of $\varphi_X$ with respect to the initial cluster $(\delta_{T_1}, \ldots, \delta_{T_r})$.

**12.3. Examples (Dimension vectors of $B_i$-modules).** Let $Q$ be a quiver with underlying graph $\begin{tikzcd} 1 \arrow{r} & 2 \arrow{r} & 3 \end{tikzcd}$ and let $i := (3,1,2,3,1,2)$. Thus $\Gamma_i$ looks as follows:

```
\begin{tikzpicture}
  \draw (0,0) node {1};
  \draw (1,1) node {2};
  \draw (1,-1) node {3};
  \draw (0,-1) node {4};
  \draw (-1,0) node {5};
  \draw (0,1) node {6};
  \draw (0,0) -- (1,1);
  \draw (0,0) -- (1,-1);
  \draw (0,0) -- (0,1);
  \draw (0,0) -- (-1,0);
  \draw (0,0) -- (0,-1);
\end{tikzpicture}
```
The following picture shows the quiver $\Gamma_{V_i}$ of $\text{End}_A(V_i)^{\text{op}}$ where the vertices corresponding to the modules $V_k$.

Here is the quiver $\Gamma'_{V_i}$ whose vertices are the dimension vectors $\text{dim}_{B_i}(\text{Hom}_A(V_i, V_k))$:

Next, let us look at an example of type $\tilde{A}_2$. Thus, let $Q$ be a quiver with underlying graph

and let $i := (3, 2, 1, 3, 2, 1)$. The quiver $\Gamma_{V_i}$ of $\text{End}_A(V_i)^{\text{op}}$ looks as follows:

Here is the quiver $\Gamma'_{V_i}$:
12.4. Example (Mutations via dimension vectors). Let $Q$ be a quiver with underlying graph $1 \rightarrow 2 \rightarrow 3$ and let $i := (i_7, \ldots, i_1) := (1, 3, 2, 1, 3, 2, 1)$ be a reduced expression. As before, let $V_i = V_1 \oplus \cdots \oplus V_7$. The indecomposable $C_w$-projective-injectives are $V_5, V_6$ and $V_7$. Let us compute the dimension vectors $\dim(B_i(\text{Hom}_{\Lambda}(V_i, M_k)))$.

\[
\begin{align*}
\dim(\Delta_1) &= \begin{pmatrix} 6 & 2 & 1 \\ 3 & 1 & 0 \\ 2 & 0 & 0 \end{pmatrix} \\
\dim(\Delta_2) &= \begin{pmatrix} 6 & 2 & 1 \\ 3 & 1 & 0 \\ 2 & 0 & 0 \end{pmatrix} \\
\dim(\Delta_3) &= \begin{pmatrix} 2 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \\
\dim(\Delta_4) &= \begin{pmatrix} 3 & 2 & 1 \\ 2 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix} \\
\dim(\Delta_5) &= \begin{pmatrix} 2 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \\
\dim(\Delta_6) &= \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix} \\
\dim(\Delta_7) &= \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.
\end{align*}
\]

Here is the quiver $\Gamma_i$:

The following picture shows the quiver $\Gamma'_V$. Its vertices are the dimension vectors of the $\text{End}_{\Lambda}(V_i)^{\text{op}}$-modules $\text{Hom}_{\Lambda}(V_i, V_k)$. These dimension vectors can be constructed easily using Lemma 9.8.

Now let us mutate the $\Lambda$-module $V_4$. We have

\[
\dim(B_i(\text{Hom}_{\Lambda}(V_i, V_4))) = \begin{pmatrix} 12 & 4 & 2 \\ 6 & 2 & 1 \end{pmatrix}.
\]

We have to look at all arrows starting and ending in the corresponding vertex of $\Gamma'_V$, and add up the entries of the attached dimension vectors, as explained in Section 12.2. Since

\[
\begin{vmatrix} 13 & 4 & 2 \\ 6 & 2 & 1 \end{vmatrix} + 2 \cdot \begin{vmatrix} 6 & 2 & 1 \\ 3 & 1 & 0 \end{vmatrix} = 70 > 69 = \begin{vmatrix} 9 & 3 & 1 \\ 4 & 2 & 2 \end{vmatrix} + 2 \cdot \begin{vmatrix} 8 & 2 & 1 \\ 4 & 1 & 0 \end{vmatrix},
\]

we get

\[
\dim(B_i(\text{Hom}_{\Lambda}(V_i, V'_4))) = \begin{pmatrix} 13 & 4 & 2 \\ 6 & 2 & 1 \end{pmatrix} + 2 \cdot \begin{pmatrix} 6 & 2 & 1 \\ 3 & 1 & 0 \end{pmatrix} - 12 \cdot \begin{pmatrix} 8 & 2 & 1 \\ 6 & 2 & 1 \end{pmatrix} = \begin{pmatrix} 13 & 4 & 2 \\ 6 & 2 & 1 \end{pmatrix}
\]

and the quiver $\Gamma'_{\mu_{V_4}(V_i)}$ looks as follows:
Note that we cannot control how the arrows between vertices corresponding to the three indecomposable $C_w$-projective-injectives behave under mutation. But this does not matter, because these arrows are not needed for the mutation of seeds and clusters. In the picture, we indicate the missing information by lines of the form \[\cdots\]. This process can be iterated, and our theory says that each of the resulting dimension vectors determines uniquely a cluster variable.

12.5. Mutations via $\Delta$-dimension vectors. Using Lemma 9.8 we can explicitly compute the dimension vector of the $B_i$-module $\Delta_s = \text{Hom}_\Lambda(V_i, M_s)$ for all $1 \leq s \leq r$. Recall that the $k$th entry of this dimension vector is just $\text{dim} \text{Hom}_\Lambda(V_k, M_s)$. Thus, the $K$-dimension of $\Delta_s$ is

$$
\text{dim}(\Delta_s) = \text{dim} \text{Hom}_\Lambda(V_i, M_s) = \sum_{k=1}^{r} \text{dim} \text{Hom}_\Lambda(V_k, M_s).
$$

Define

$$d_\Delta := (\text{dim}(\Delta_1), \ldots, \text{dim}(\Delta_r)).$$

Now let $R = R_1 \oplus \cdots \oplus R_r$ be a basic $C_w$-maximal rigid $\Lambda$-module, and suppose that $R_k$ is not $C_w$-projective-injective. Then we can mutate $R$ in direction $R_k$. We obtain two exchange sequences

$$0 \rightarrow R_k \rightarrow R' \rightarrow R_k^* \rightarrow 0 \quad \text{and} \quad 0 \rightarrow R_k^* \rightarrow R'' \rightarrow R_k \rightarrow 0$$

with $R', R'' \in \text{add}(R/R_k)$.

For brevity, set

$$d_s := \text{dim}_\Lambda(\text{Hom}_\Lambda(V_i, R_s))$$

for all $1 \leq s \leq r$. Similarly to the definition of $\Gamma'_R$ in Section 12.2 let $\Gamma''_R$ be the quiver which is obtained from the quiver of $\text{End}_\Lambda(R)^{\text{op}}$ by replacing the vertex corresponding to $R_s$ by the $\Delta$-dimension vector $d_s$.

For $d = (d_1, \ldots, d_r)$ and $f = (f_1, \ldots, f_r)$ in $\mathbb{Z}^r$ define

$$d \cdot f := \sum_{i=1}^{r} d_i f_i.$$

Proposition 12.6. The $\Delta$-dimension vector of the $B_i$-module $\text{Hom}_\Lambda(V_i, R_k^*)$ is

$$d_k^* := \begin{cases} 
-d_k + \sum_{d_i \rightarrow d_k} d_i & \text{if } \sum_{d_i \rightarrow d_k} d_i \cdot d_\Delta > \sum_{d_k \rightarrow d_j} d_j \cdot d_\Delta, \\
-d_k + \sum_{d_k \rightarrow d_j} d_j & \text{otherwise}.
\end{cases}$$

Here the sums are taken over all arrows of the quiver of $\Gamma''_R$ which start, respectively end in the vertex $d_k$.

Proof. This follows immediately from our results in Section 12.2

12.6. Example (Mutations via $\Delta$-dimension vectors). We repeat Example 12.4, but this time we work with $\Delta$-dimension vectors. Let $Q$ and $i$ be as before. The following
picture shows the quiver $\Gamma''_{V_i}$. Its vertices are the $\Delta$-dimension vectors of the $\text{End}_\Lambda(V_i)^\text{op}$-modules $\text{Hom}_\Lambda(V_i, V_k)$.

Again, let us mutate the $\Lambda$-module $V_4$. We have

$$\dim_\Lambda(\text{Hom}_\Lambda(V_i, V_4)) = \begin{pmatrix} 0 & 1 & 1 \\ 0 & 0 & 0 \end{pmatrix}.$$  

We have to look at all arrows starting and ending in the corresponding vertex of $\Gamma''_{V_i}$, and to add up the entries of the attached $\Delta$-dimension vectors, as explained in the previous section. In this example it is clear that the ingoing arrows yield the required larger dimension, since the calculation with outgoing arrows would produce a $\Delta$-dimension vector with negative entries, which is not possible. Thus the quiver $\Gamma''_{\mu V_4(V_i)}$ looks as follows:

13. A SEQUENCE OF MUTATIONS FROM $V_i$ TO $T_i$

13.1. The algorithm. Let $i := (i_r, \ldots, i_1)$ be a reduced expression of a Weyl group element. For $1 \leq i, j \leq n$ set

$$q_{ij} := \begin{cases} -c_{ij} & \text{if } i \neq j, \\ 0 & \text{otherwise}. \end{cases}$$

(The $c_{ij}$ are the entries of the Cartan matrix $C$ of our Kac-Moody Lie algebra $\mathfrak{g}$, see Section 4.1. Note that this definition of $q_{ij}$ is equivalent to the one in Section 2.4.) As before, we define a quiver $\Gamma_i$ as follows: The vertices of $\Gamma_i$ are $1, 2, \ldots, r$. For $1 \leq s, t \leq r$ there are $q_{is, it}$ arrows from $s$ to $t$ provided $t^+ \geq s^+ > t > s$. These are called the ordinary arrows of $\Gamma_i$. Furthermore, for each $1 \leq s \leq r$ there is an arrow $s \to s^-$ provided $s^- > 0$. These are the horizontal arrows of $\Gamma_i$.

As before, let $V_i = V_1 \oplus \cdots \oplus V_r$ and $M_i = M_1 \oplus \cdots \oplus M_r$. We know that the quiver $\Gamma_i$ can be identified with the quiver $\Gamma_{V_i}$ of the endomorphism algebra $B_i = \text{End}_\Lambda(V_i)^\text{op}$. The vertices of $\Gamma_{V_i}$ are labeled by $V_1, \ldots, V_r$. More precisely, the vertex $s$ of $\Gamma_i$ corresponds to the vertex $V_s = M[s, s_{\min}]$ of $\Gamma_{V_i}$, where $1 \leq s \leq r$. 

13.2. The algorithm. Let $i := (i_r, \ldots, i_1)$ be a reduced expression of a Weyl group element. For $1 \leq i, j \leq n$ set

$$q_{ij} := \begin{cases} -c_{ij} & \text{if } i \neq j, \\ 0 & \text{otherwise}. \end{cases}$$

(The $c_{ij}$ are the entries of the Cartan matrix $C$ of our Kac-Moody Lie algebra $\mathfrak{g}$, see Section 4.1. Note that this definition of $q_{ij}$ is equivalent to the one in Section 2.4.) As before, we define a quiver $\Gamma_i$ as follows: The vertices of $\Gamma_i$ are $1, 2, \ldots, r$. For $1 \leq s, t \leq r$ there are $q_{is, it}$ arrows from $s$ to $t$ provided $t^+ \geq s^+ > t > s$. These are called the ordinary arrows of $\Gamma_i$. Furthermore, for each $1 \leq s \leq r$ there is an arrow $s \to s^-$ provided $s^- > 0$. These are the horizontal arrows of $\Gamma_i$.

As before, let $V_i = V_1 \oplus \cdots \oplus V_r$ and $M_i = M_1 \oplus \cdots \oplus M_r$. We know that the quiver $\Gamma_i$ can be identified with the quiver $\Gamma_{V_i}$ of the endomorphism algebra $B_i = \text{End}_\Lambda(V_i)^\text{op}$. The vertices of $\Gamma_{V_i}$ are labeled by $V_1, \ldots, V_r$. More precisely, the vertex $s$ of $\Gamma_i$ corresponds to the vertex $V_s = M[s, s_{\min}]$ of $\Gamma_{V_i}$, where $1 \leq s \leq r$. 

13.2. The algorithm. Let $i := (i_r, \ldots, i_1)$ be a reduced expression of a Weyl group element. For $1 \leq i, j \leq n$ set

$$q_{ij} := \begin{cases} -c_{ij} & \text{if } i \neq j, \\ 0 & \text{otherwise}. \end{cases}$$

(The $c_{ij}$ are the entries of the Cartan matrix $C$ of our Kac-Moody Lie algebra $\mathfrak{g}$, see Section 4.1. Note that this definition of $q_{ij}$ is equivalent to the one in Section 2.4.) As before, we define a quiver $\Gamma_i$ as follows: The vertices of $\Gamma_i$ are $1, 2, \ldots, r$. For $1 \leq s, t \leq r$ there are $q_{is, it}$ arrows from $s$ to $t$ provided $t^+ \geq s^+ > t > s$. These are called the ordinary arrows of $\Gamma_i$. Furthermore, for each $1 \leq s \leq r$ there is an arrow $s \to s^-$ provided $s^- > 0$. These are the horizontal arrows of $\Gamma_i$. 

As before, let $V_i = V_1 \oplus \cdots \oplus V_r$ and $M_i = M_1 \oplus \cdots \oplus M_r$. We know that the quiver $\Gamma_i$ can be identified with the quiver $\Gamma_{V_i}$ of the endomorphism algebra $B_i = \text{End}_\Lambda(V_i)^\text{op}$. The vertices of $\Gamma_{V_i}$ are labeled by $V_1, \ldots, V_r$. More precisely, the vertex $s$ of $\Gamma_i$ corresponds to the vertex $V_s = M[s, s_{\min}]$ of $\Gamma_{V_i}$, where $1 \leq s \leq r$. 

13.2. The algorithm. Let $i := (i_r, \ldots, i_1)$ be a reduced expression of a Weyl group element. For $1 \leq i, j \leq n$ set

$$q_{ij} := \begin{cases} -c_{ij} & \text{if } i \neq j, \\ 0 & \text{otherwise}. \end{cases}$$

(The $c_{ij}$ are the entries of the Cartan matrix $C$ of our Kac-Moody Lie algebra $\mathfrak{g}$, see Section 4.1. Note that this definition of $q_{ij}$ is equivalent to the one in Section 2.4.) As before, we define a quiver $\Gamma_i$ as follows: The vertices of $\Gamma_i$ are $1, 2, \ldots, r$. For $1 \leq s, t \leq r$ there are $q_{is, it}$ arrows from $s$ to $t$ provided $t^+ \geq s^+ > t > s$. These are called the ordinary arrows of $\Gamma_i$. Furthermore, for each $1 \leq s \leq r$ there is an arrow $s \to s^-$ provided $s^- > 0$. These are the horizontal arrows of $\Gamma_i$. 

As before, let $V_i = V_1 \oplus \cdots \oplus V_r$ and $M_i = M_1 \oplus \cdots \oplus M_r$. We know that the quiver $\Gamma_i$ can be identified with the quiver $\Gamma_{V_i}$ of the endomorphism algebra $B_i = \text{End}_\Lambda(V_i)^\text{op}$. The vertices of $\Gamma_{V_i}$ are labeled by $V_1, \ldots, V_r$. More precisely, the vertex $s$ of $\Gamma_i$ corresponds to the vertex $V_s = M[s, s_{\min}]$ of $\Gamma_{V_i}$, where $1 \leq s \leq r$. 

13.2. The algorithm. Let $i := (i_r, \ldots, i_1)$ be a reduced expression of a Weyl group element. For $1 \leq i, j \leq n$ set

$$q_{ij} := \begin{cases} -c_{ij} & \text{if } i \neq j, \\ 0 & \text{otherwise}. \end{cases}$$

(The $c_{ij}$ are the entries of the Cartan matrix $C$ of our Kac-Moody Lie algebra $\mathfrak{g}$, see Section 4.1. Note that this definition of $q_{ij}$ is equivalent to the one in Section 2.4.) As before, we define a quiver $\Gamma_i$ as follows: The vertices of $\Gamma_i$ are $1, 2, \ldots, r$. For $1 \leq s, t \leq r$ there are $q_{is, it}$ arrows from $s$ to $t$ provided $t^+ \geq s^+ > t > s$. These are called the ordinary arrows of $\Gamma_i$. Furthermore, for each $1 \leq s \leq r$ there is an arrow $s \to s^-$ provided $s^- > 0$. These are the horizontal arrows of $\Gamma_i$. 

As before, let $V_i = V_1 \oplus \cdots \oplus V_r$ and $M_i = M_1 \oplus \cdots \oplus M_r$. We know that the quiver $\Gamma_i$ can be identified with the quiver $\Gamma_{V_i}$ of the endomorphism algebra $B_i = \text{End}_\Lambda(V_i)^\text{op}$. The vertices of $\Gamma_{V_i}$ are labeled by $V_1, \ldots, V_r$. More precisely, the vertex $s$ of $\Gamma_i$ corresponds to the vertex $V_s = M[s, s_{\min}]$ of $\Gamma_{V_i}$, where $1 \leq s \leq r$.
Recall that for $1 \leq j \leq n$ and $1 \leq k \leq r + 1$, we defined
\[ k[j] := |\{1 \leq s \leq k - 1 \mid i_s = j\}|, \]
\[ t_j := (r + 1)[j], \]
\[ k_{\min} := \min\{1 \leq s \leq r \mid i_s = i_k\}. \]
Now we describe an algorithm which yields a sequence of mutations starting with $\Gamma_{\nabla_1}$ and ending with $\Gamma_{T_1}$ (see Section 9.3 for the definition of $T_1$). The proof is done by induction on $r - n$.

Before going into details let us describe the general idea of this algorithm. Assume that $Q$ is the linearly oriented quiver
\[
\begin{array}{cccccc}
m & m - 1 & \cdots & 2 & 1 \\
\end{array}
\]
of type $A_m$. We would like to find a sequence of mutations which transforms $Q$ into the quiver $Q^{\text{op}}$
\[
\begin{array}{cccccc}
m & m - 1 & \cdots & 2 & 1 \\
\end{array}
\]
with opposite linear orientation. This can be done by applying the following $m - 1$ sequences of mutations:
\[ Q^1 := \mu_{m-1} \cdots \mu_2 \mu_1(Q), \quad Q^2 := \mu_{m-2} \cdots \mu_2 \mu_1(Q^1), \quad \ldots, \quad Q^{m-1} := \mu_1(Q^{m-2}). \]
Now one easily checks that $Q^{m-1} = Q^{\text{op}}$. If we delete all ordinary arrows of $\Gamma_i$, we obtain a disjoint union of linearly oriented quivers of type $A_m$, for various $m_i \geq 1$. The main idea of the following algorithm is to apply a sequence of mutations to $\Gamma_1$ which (in the same way as explained above) reverses the orientation of these subquivers of type $A_{m_i}$ without causing too many changes for the remaining ordinary arrows.

In the following, we just ignore the symbols of the form $M[a, b]$ in case $a < b$.

**Step 1:** We mutate the following vertices of $\Gamma^0_{\nabla_i} := \Gamma_{\nabla_i}$ in the given order:
\[ M[1_{\min}^{(1[i_1])}, 1_{\min}^{(1[i_1])}], M[1_{\min}^{(1[i_1]+1)}, 1_{\min}^{(1[i_1])}], M[1_{\min}^{(1[i_1]+2)}, 1_{\min}^{(1[i_1])}], \ldots, M[1_{\min}^{(t_{i_1}-2)}, 1_{\min}^{(1[i_1])}]. \]
Under the identification $\Gamma_{\nabla_i} \equiv \Gamma_i$, this sequence of mutations corresponds to the sequence of mutations
\[ \overrightarrow{\mu}_1 := \mu_{(r_{i_1}-1)} \circ \cdots \circ \mu_{1_{\min}} \circ \mu_{1_{\min}}. \]
We obtain a new quiver $\Gamma^1_{\nabla_i}$ with $r_1$ new vertices
\[ M[1_{\min}^{(1[i_1]+1)}, 1_{\min}^{(1[i_1]+1)}], M[1_{\min}^{(1[i_1]+2)}, 1_{\min}^{(1[i_1]+1)}], M[1_{\min}^{(1[i_1]+3)}, 1_{\min}^{(1[i_1]+1)}], \]
\[ \ldots, M[1_{\min}^{(t_{i_1}-1)}, 1_{\min}^{(1[i_1]+1)}]. \]

**Step 2:** We mutate the following vertices of $\Gamma^1_{\nabla_i}$ in the following order:
\[ M[2_{\min}^{(2[i_2])}, 2_{\min}^{(2[i_2])}], M[2_{\min}^{(2[i_2]+1)}, 2_{\min}^{(2[i_2])}], M[2_{\min}^{(2[i_2]+2)}, 2_{\min}^{(2[i_2])}], \ldots, M[2_{\min}^{(t_{i_2}-2)}, 2_{\min}^{(2[i_2])}]. \]
This mutation sequence corresponds to
\[ \overrightarrow{\mu}_2 := \mu_{(r_{i_2}-1)} \circ \cdots \circ \mu_{2_{\min}} \circ \mu_{2_{\min}}. \]
We obtain a new quiver $\Gamma_{V_i}^2$ with $r_2$ new vertices

\[
M[2_{\text{min}}^{(2\{i_2\}+1)}, 2_{\text{min}}^{(2\{i_2\}+1)}], M[2_{\text{min}}^{(2\{i_2\}+2)}, 2_{\text{min}}^{(2\{i_2\}+1)}], M[2_{\text{min}}^{(2\{i_2\}+3)}, 2_{\text{min}}^{(2\{i_2\}+1)}], \ldots, M[2_{\text{min}}^{(t_{i_2}-1)}, 2_{\text{min}}^{(2\{i_2\}+1)}].
\]

**Step k**: We mutate the following vertices of $\Gamma_{V_i}^{k-1}$ in the following order:

\[
M[k_{\text{min}}^{(k_{i_k})}, k_{\text{min}}^{(k_{i_k}+1)}], M[k_{\text{min}}^{(k_{i_k}+1)}, k_{\text{min}}^{(k_{i_k})}], M[k_{\text{min}}^{(k_{i_k}+2)}, k_{\text{min}}^{(k_{i_k})}], \ldots, M[k_{\text{min}}^{(t_{i_k}-1)}, k_{\text{min}}^{(k_{i_k})}].
\]

This mutation sequence corresponds to

\[
\vec{\mu}_k := \mu_{k_{\text{min}}}^{(r_k-1)} \circ \cdots \circ \mu_{k_{\text{min}}}^{(1)} \circ \mu_{k_{\text{min}}}.
\]

We obtain a new quiver $\Gamma_{V_i}^k$ with $r_k$ new vertices

\[
M[k_{\text{min}}^{(k_{i_k}+1)}], k_{\text{min}}^{(k_{i_k}+1)}], M[k_{\text{min}}^{(k_{i_k}+2)}, k_{\text{min}}^{(k_{i_k}+1)}], M[k_{\text{min}}^{(k_{i_k}+3)}, k_{\text{min}}^{(k_{i_k}+1)}], \ldots, M[k_{\text{min}}^{(t_{i_k}-1)}, k_{\text{min}}^{(k_{i_k}+1)}].
\]

The algorithm stops when all vertices are of the form $M[k_{\text{min}}^{k_{\text{max}}}, k]$. This will happen after

\[
r(i) := \sum_{j=1}^{n} \frac{t_j(t_j - 1)}{2}
\]

mutations. Define

\[
\mu_i := \vec{\mu}_e \circ \cdots \circ \vec{\mu}_2 \circ \vec{\mu}_1.
\]

Thus we have

\[
\mu_i(V_i) = T_i.
\]

As an example, assume $Q$ is a Dynkin quiver of type $E_8$. Thus the underlying graph of $Q$ looks as follows:

```
    7
  5 — 6 — 8 — 4 — 3 — 2 — 1
```

Let $c := s_8 s_7 s_6 s_5 s_4 s_3 s_2 s_1$. Then $w := c^{10}$ is the longest element in the Weyl group $W$ of $Q$, and $i := (8, \ldots, 2, 1, \ldots, 8, \ldots, 2, 1)$ is a reduced expression (with 120 entries) of $w$. We get $t_j = 15$ for all 8 vertices $j$ of $Q$. Then our algorithm says that starting with $V_i$ we reach $T_i$ after $r(i) = 8 \cdot 105 = 840$ mutations.

We now want to describe what happens to the quiver $\Gamma_{V_i}^{k-1}$ when we apply the mutation sequence $\vec{\mu}_k$. First, we need some notation:

For each $1 \leq j \leq n$

\[
p_j := \min\{1 \leq s \leq r \mid i_s = j\},
\]

\[
u_j := \min\{0, k \leq s \leq r \mid i_s = j\}.
\]

Note that $p_j^{(0)} = p_j$. The sequence

\[(p_j^{(0)}, p_j^{(1)}, \ldots, p_j^{(r_{u_j} - 1)})\]
of vertices of $\Gamma_{V_i}^{k-1}$ is called the $j$-chain of $\Gamma_{V_i}^{k-1}$, provided $u_j \neq 0$. If $u_j = 0$, then we have an empty $j$-chain. The sequence

$$(p_j^{(0)}, p_j^{(1)}, \ldots, p_j^{(t_j - 1)})$$

is the extended $j$-chain.

Each full subgraph of $\Gamma_{V_i}^{k-1}$ given by the vertices of a single extended $j$-chain looks as follows:

$$
\begin{align*}
&\vdots & \vdots & \vdots & \vdots \\
p_j^{(t_j - 1)} & \rightarrow & \cdots & \rightarrow & p_j^{(r_{uj} + 1)} \\
& \rightarrow & p_j^{(r_{uj})} & \rightarrow & \cdots & \rightarrow & p_j^{(r_{uj} - 1)} \\
& \rightarrow & \cdots & \rightarrow & p_j^{(2)} & \rightarrow & p_j^{(1)} \\
& \rightarrow & \cdots & \rightarrow & p_j^{(0)} \\
\end{align*}
$$

The arrows of the extended $j$-chains ($1 \leq j \leq n$), are the horizontal arrows of $\Gamma_{V_i}^{k-1}$. In the mutation sequence

$$
\vec{\mu}_r \circ \cdots \circ \vec{\mu}_{k+1} \circ \vec{\mu}_k
$$

there are no mutations at the vertices $p_j^{(r_{uj})}, p_j^{(r_{uj} + 1)}, \ldots, p_j^{(t_j - 1)}$. These are called the frozen vertices of $\Gamma_{V_i}^{k-1}$.

To describe the quiver $\Gamma_{V_i}^k$, it is enough to study the effect of $\vec{\mu}_k$ on the $n - 1$ full subgraphs of $\Gamma_{V_i}^k$ which consist of the $i_k$-chain together with one extended $j$-chain, where $1 \leq j \leq n$ and $j \neq i_k$.

For brevity, set $s = s^{(0)} = k_{\text{min}}$, $t = t^{(0)} = p_j$. Let $q = q_{k,j}$ be the number of edges between $i_k$ and $j$ in the underlying graph of $Q$. The following picture shows how the arrows between the $i_k$-chain and an extended $j$-chain in $\Gamma_{V_i}^{k-1}$ look like (we have $1 \leq j \leq n$ with $i_k \neq j$, and we use the notation $u \rightarrow v$ if there are $q$ arrows from $u$ to $v$):

Here $s^{(a_i)}$ belongs to the $i_k$-chain, and $t^{(b_i)}$ belongs to the extended $j$-chain for all $1 \leq i \leq z$. (The $q$ arrows from $s^{(a_z)}$ to $t^{(b_z)}$ do not exist necessarily. But the first $q$ arrows between the $i_k$-chain and the $j$-chain (counted from the right) always start at the $i_k$-chain. We do not display any arrows between frozen vertices, they don’t play any role.)

The mutation sequence $\vec{\mu}_k$ consists of mutations at the vertices $s^{(0)}, s^{(1)}, \ldots, s^{(r_{k-1})}$. By definition,

$$
\Gamma_{V_i}^k := \vec{\mu}_k \left( \Gamma_{V_i}^{k-1} \right).
$$

After applying $\vec{\mu}_k$, the horizontal arrows of the $i_k$-chain stay the same, except the arrow $s^{(r_k)} \rightarrow s^{(r_{k-1})}$ changes its orientation and becomes $s^{(r_k)} \leftarrow s^{(r_{k-1})}$. The vertex $s^{(r_{k-1})}$ becomes an additional frozen vertex of $\Gamma_{V_i}^k$.

The arrows between the $i_k$-chain and the $j$-chain change as follows:

$$(s^{(a_z - 1)} \rightarrow s^{(a_{z-1})} \rightarrow \cdots \rightarrow s^{(a_1 - 1)})$$

(In case $s^{(a_1)} = s$, the $q$ arrows from $s^{(a_1 - 1)}$ to $t^{(b_1)}$ do not exist.)
We illustrate this again in a more explicit example: Here is a possible subgraph before we apply $\mu_k$, where $r_k = 8$ and $r_u = 6$:

\[
\begin{align*}
s\langle t_k \rangle \rightsquigarrow \cdots \rightsquigarrow s\langle 8 \rangle \rightsquigarrow s\langle 7 \rangle \rightarrow s\langle 6 \rangle \rightarrow s\langle 5 \rangle \rightarrow s\langle 4 \rangle \rightarrow s\langle 3 \rangle \rightarrow s\langle 2 \rangle \rightarrow s\langle 1 \rangle \rightarrow s\langle 0 \rangle \\
t\langle t_j \rangle \rightsquigarrow \cdots \rightsquigarrow t\langle 8 \rangle \rightsquigarrow t\langle 7 \rangle \rightarrow t\langle 6 \rangle \rightarrow t\langle 5 \rangle \rightarrow t\langle 4 \rangle \rightarrow t\langle 3 \rangle \rightarrow t\langle 2 \rangle \rightarrow t\langle 1 \rangle \rightarrow t\langle 0 \rangle 
\end{align*}
\]
(The numbers $r_k$ and $r_u$ are determined by the orientation of the horizontal arrows in the above picture.)

This is how it looks like after we applied $\mu_k$ to the $r_k$ vertices of the $i_k$-chain:

\[
\begin{align*}
s\langle t_k \rangle \rightsquigarrow \cdots \rightsquigarrow s\langle 8 \rangle \rightsquigarrow s\langle 7 \rangle \rightarrow s\langle 6 \rangle \rightarrow s\langle 5 \rangle \rightarrow s\langle 4 \rangle \rightarrow s\langle 3 \rangle \rightarrow s\langle 2 \rangle \rightarrow s\langle 1 \rangle \rightarrow s\langle 0 \rangle \\
t\langle t_j \rangle \rightsquigarrow \cdots \rightsquigarrow t\langle 8 \rangle \rightarrow t\langle 7 \rangle \rightarrow t\langle 6 \rangle \rightarrow t\langle 5 \rangle \rightarrow t\langle 4 \rangle \rightarrow t\langle 3 \rangle \rightarrow t\langle 2 \rangle \rightarrow t\langle 1 \rangle \rightarrow t\langle 0 \rangle 
\end{align*}
\]
Again, possible arrows between frozen vertices are not shown.

Note that if we start with our initial $C_w$-maximal rigid module $V_i$, and if we only perform the $r(i)$ mutations described in the algorithm, then we obtain the subset

\[\{ M[b, a] \mid 1 \leq a \leq b \leq r, i_a = i_b \}\]

of the set of indecomposable rigid modules of $C_w$. In particular, this subset contains all modules $M_k = M[k, k]$ where $1 \leq k \leq r$. The next theorem describes the precise exchange relation obtained in each of the $r(i)$ steps of the algorithm above.

We use our description of mutations via $\Delta$-dimension vectors from Section 12.5 in order to show that the mutation $M[s, s_{\min}^{(k[i])}]^* \cdot M[s, s_{\min}^{(k[i])}]$ is indeed $M[s^+, s_{\min}^{(k[i]+1)}]$. 

In formula (7) below we just write $M[b, a]$ instead of $\delta_M[b, a]$. (Recall that for any $\Lambda$-module $X$ and any constructible function $f \in \mathcal{M}$ we have $\delta_X(f) := f(X)$. This defines an element $\delta_X$ in $\mathcal{M}^*$.)

**Theorem 13.1** (Generalized determinantal identities). Let $M_1 = M_1 \oplus \cdots \oplus M_r$. Then for $1 \leq k, s \leq r$ with $i_s = i_k$ we have

\[
M[s, s_{\min}^{(k[i])}] \cdot M[s^+, s_{\min}^{(k[i]+1)}] = M[s^+, s_{\min}^{(k[i])}] \cdot M[s, s_{\min}^{(k[i]+1)}] + \prod_{t^+ \geq s^+, t^+ \neq s} M[t, i_{\min}^{(k[i])}]^{q_{ts}} \prod_{t^+ \geq s^+, t^+ > s_{\min}} M[t, i_{\min}^{(k[i])}]^{q_{ts}}.
\]

**Proof.** Formula (7) is just an exchange relation corresponding to the mutation of the module $M[s, s_{\min}^{(k[i])}]$ with $M[s, s_{\min}^{(k[i])}]^* = M[s^+, s_{\min}^{(k[i]+1)}]$. More precisely, the mutation of $M[s, s_{\min}^{(k[i])}]$ happens during the mutation sequence $\mu_k$, which is part of the mutation sequence $\mu_i$. $\square$

**Remark 13.2.** It is not hard to see that the above theorem can be also stated as follows: For $1 \leq t < s \leq r$ with $i_s = i_j = i$ we have

\[
M[s, t^+] M[s^-, t] = M[s, t] M[s^-, t^+] + \prod_{j \in I \setminus \{i\}} M[s^{-}(j), t^+(j)]^{q_{ij}},
\]

where in addition to the notation in 9.8 we set $t^+(j) := \min\{r + 1, t + 1 \leq k \leq r \mid i_k = j\}$. Fomin and Zelevinsky [FZ1] Theorem 1.17 prove generalized determinantal identities associated to pairs of Weyl group elements for all Dynkin cases (including the non-simply
Corollary 13.3. The functions $\delta_{M_1}, \ldots, \delta_{M_r}$ are algebraically independent. In particular, $\mathbb{C}[\delta_{M_1}, \ldots, \delta_{M_r}]$, the subalgebra of $\mathcal{M}^*$ generated by the $\delta_{M_r}$'s is just a polynomial ring in $r$ variables.

Proof. Clearly, the functions $\delta_{M_1,1,\min}, \ldots, \delta_{M_1,r,\min}$ are algebraically independent, since $V_k = M[k, k_{\min}]$ and any product of the functions $\delta_{V_1}, \ldots, \delta_{V_r}$ lies in the dual semicanonical basis. Here we use that $V_i$ is rigid and then we apply [GLS1, Theorem 1.1]. We claim that each function $\delta_{M[b,a]}$ with $1 \leq a \leq b \leq r$ and $i_a = i_b$ is a rational function in $\delta_{M_1}, \ldots, \delta_{M_r}$. In particular, each $\delta_{V_k}$ is a rational function in $\delta_{M_1}, \ldots, \delta_{M_r}$. This implies that $\delta_{M_1}, \ldots, \delta_{M_r}$ are algebraically independent.

We prove our claim by induction on $r$ and on the length $l([b,a]) := |\{a \leq k \leq b \mid i_k = i_b\}|$ of the interval $[b,a]$. For $r = 1$ the statement is clear. Also, if $l([b,a]) = 1$, then $M[b,a] = M_1$ and we are done as well. Thus assume by induction that our claim is true for all intervals $[d,c]$ of length at most $m$ for some $m \geq 1$. All intervals of length $m + 1$ are of the form $[b^+,a]$ for some $1 \leq a \leq b \leq r$. We have $a = b^{(k[i_b])}$ for some $1 \leq k \leq r$. We also assume by induction that our claim holds for all intervals $[d,c]$ with $b^+ > d$. Our formula (7) yields

\begin{align}
(8) \quad M[b^+,a] &= \frac{1}{M[b,a^+]} \cdot (M[b,a] \cdot M[b^+,a^+]) - \\
&= \frac{1}{M[b,a^+]} \cdot \left( \prod_{l \geq b^+, \min \leq t > b} M[t, i^{(k[i_l])}_{\min}]_{q_{b^+t}} \cdot \prod_{l \geq b^+, \min \leq t > b_{\min}} M[t, i^{(k[i_l])}_{\min}]_{q_{b^+t}} \right).
\end{align}

The intervals on the right hand side of this equation all have either length at most $m$, or they are of the form $[d,c]$ with $b^+ > d$. This finishes the proof. \hfill \square

In fact, we will show that for any $\Lambda$-module $X \in \mathcal{C}$, we have $\delta_X \in \mathbb{C}[\delta_{M_1}, \ldots, \delta_{M_r}]$, see Theorem 15.1. In particular, for all $1 \leq k \leq r$ the rational function $\delta_{V_k}$ is a polynomial in $\delta_{M_1}, \ldots, \delta_{M_r}$.

Another proof of the polynomiality of the functions $\delta_{M[b,a]}$ was found by Kedem and Di Francesco [DFK] Lemma B.7, using ideas of Fomin and Zelevinsky (in particular [BFZ, Lemma 4.2]). We thank these four mathematicians for communicating their insights to us at MSRI in March 2008.

13.2. Example. Let $Q$ be a quiver with underlying graph

```
1 -- 2
|   |
3   4
|   |
2
```

Here we use the notation $i \rightarrow j$ if there are $a$ edges between $i$ and $j$. Let $i := (i_{10}, \ldots, i_1) := (2, 3, 2, 1, 2, 1, 3, 1, 2, 1)$. This is a reduced expression for a Weyl group.

laced cases). Using the material of Section 7 formula (7) can be seen as a generalization of some of their identities to the symmetric Kac-Moody case.
element in $W_Q$. The quiver $\Gamma_i$ looks as follows:

For the mutation sequence $\mu_i$ we get

$$
\mu_i = \mu_{10} \circ \cdots \circ \mu_2 \circ \mu_1 = (id) \circ (id) \circ (\mu_2) \circ (id) \circ (\mu_6 \mu_2) \circ (\mu_1) \circ (\mu_4) \circ (\mu_3 \mu_1) \circ (\mu_8 \mu_6 \mu_2) \circ (\mu_5 \mu_3 \mu_1)
$$

Here are the quivers $\Gamma^k_i$: 
Thus, we have
\[ r \]
By our double induction (on \( M \) above equations, we can write the functions \( \delta \))
Remarkably, this rational function is a polynomial.

\[ M[8, s_{\min}^{(k[i_{s}] \rangle} := M[6, 6^{(2[i_{s}])}] = M[6, 2] \]
we get the following:
\[ M[6, 2] \cdot M[8, 6] = M[8, 2] \cdot M[6, 6] + M[7, 3]^3 \cdot M[4, 4]^2 \]
\[ (s = 6, k = 2). \]

Thus, we have
\[ M[8, 2] = \frac{1}{M[6, 6]} \left( M[6, 2] \cdot M[8, 6] - M[7, 3]^3 \cdot M[4, 4]^2 \right). \]

Similarly, we obtain
\[ M[2, 2] \cdot M[6, 6] = M[6, 2] + M[5, 3]^3 \cdot M[4, 4]^2 \]
\[ (s = 2, k = 2), \]
\[ M[6, 6] \cdot M[8, 8] = M[8, 6] + M[7, 7]^3 \]
\[ (s = 6, k = 6), \]
\[ M[5, 3] \cdot M[7, 5] = M[7, 3] \cdot M[5, 5] + M[6, 6]^3 \cdot M[4, 4]^2 \]
\[ (s = 5, k = 3), \]
\[ M[3, 3] \cdot M[5, 5] = M[5, 3] + M[4, 4]^2 \]
\[ (s = 3, k = 3), \]
\[ M[5, 5] \cdot M[7, 7] = M[7, 5] + M[6, 6]^3 \]
\[ (s = 5, k = 5). \]

By our double induction (on \( r \) and on the length of the intervals \([b, a])\), in each of the
above equations, we can write the functions \( M[6, 2], M[8, 6], M[7, 3], M[5, 3] \) and \( M[7, 5] \),
respectively, as a rational function of the functions appearing in the same equation. Now
one can use these equations to express \( \delta_{M[8, 2]} \) as a rational function in \( \delta_{M_1}, \ldots, \delta_{M_8}. \)
Remarkably, this rational function is a polynomial.

Finally, we display the dimension vectors of the modules \( M_1, \ldots, M_8: \)
\[ \beta_1(1) = 1 \quad 0 \quad 0 \quad 0 \quad 0 \quad \beta_1(2) = 3 \quad 1 \quad 0 \quad \beta_1(3) = 8 \quad 3 \quad 0 \quad \beta_1(4) = 24 \quad 8 \quad 1 \]
\[ \beta_1(5) = 40 \quad 13 \quad 2 \quad \beta_1(6) = 189 \quad 63 \quad 8 \quad \beta_1(7) = 527 \quad 176 \quad 22 \quad \beta_1(8) = 1392 \quad 465 \quad 58 \]
As an exercise, the reader can compute $\beta_i(9)$ and $\beta_i(10)$.

Exchange equations are always homogeneous. For example,

$$M[5, 3] \cdot M[7, 5] = M[7, 3] \cdot M[5, 5] + M[6, 6]^3 \cdot M[4, 4]^2$$

is an equation of degree $265^{105}_{26}$.

13.3. The shift functor in $\mathcal{C}_w$ via mutations. Fix a reduced expression $i = (i_r, \ldots, i_1)$ of some Weyl group element $w$. As before, let $T_i := I_w \oplus \Omega_w^{-1}(V_i)$. Define

$$W_i := I_w \oplus \Omega_w(V_i).$$

In Section 13.1 we defined a sequence of mutations

$$\mu_i = \mu_{r}^{s_r} \circ \cdots \circ \mu_{1}^{s_1}$$

where $1 \leq s_p \leq r$ for all $p$, such that

$$\mu_i(V_i) = \mu_{s_r}^{s_r} \circ \cdots \circ \mu_{2}^{s_2} \circ \mu_{1}^{s_1}(V_i) = T_i \quad \text{and} \quad \mu_i^{-1}(T_i) = \mu_{s_1} \circ \mu_{s_2} \circ \cdots \circ \mu_{s_r}(T_i) = V_i.$$

Clearly, if $R$ is a basic $\mathcal{C}_w$-maximal rigid module such that $R = \mu_{p_r} \circ \cdots \circ \mu_{p_1}(V_i)$, then we have $R = \mu_{p_1} \circ \cdots \circ \mu_{p_1}^{-1}(T_i)$.

Now define an involution

$$(-)^* : \{1, \ldots, r\} \setminus \{1 \leq k \leq r \mid k^+ = r + 1\} \rightarrow \{1, \ldots, r\} \setminus \{1 \leq k \leq r \mid k^+ = r + 1\}$$

by

$$\left(k^{(m)}_{\min}\right)^* := k^{(t_j - 2 - m)}_{\min},$$

where $j := i_{k_{\min}}$. Observe that every $1 \leq s \leq r$ can be written as $k^{(m)}_{\min}$ for some unique $k$ (namely $k = s$) and some unique $0 \leq m \leq t_j - 1$. The following picture illustrates how $(-)^*$ permutes the vertices of $\Gamma_i$:

$\begin{array}{cccccccc}
\kmin^{(t_j-1)} & \rightarrow & \kmin^{(t_j-2)} & \rightarrow & \kmin^{(t_j-3)} & \rightarrow & \cdots & \rightarrow & \kmin^{(2)} & \rightarrow & \kmin^{(1)} & \rightarrow & \kmin
\end{array}$

Set

$$\left(\mu_i^{-1}\right)^* := \mu_{s_1}^{s_1} \circ \mu_{s_2}^{s_2} \circ \cdots \circ \mu_{s_r}^{s_r}(T_i).$$

**Proposition 13.4.** Let $R$ be a basic $\mathcal{C}_w$-maximal rigid module which is mutation equivalent to $V_i$. Then $I_w \oplus \Omega_w^{-1}(R)$ and $I_w \oplus \Omega_w(R)$ are mutation equivalent to $V_i$. More precisely, let

$$R = \mu_{z_1} \circ \cdots \circ \mu_{z_1}(V_i) \quad \text{and} \quad R = \mu_{q_1} \circ \cdots \circ \mu_{q_1}(T_i).$$

Then we have

$$I_w \oplus \Omega_w^{-1}(R) = \mu_{z_1^*} \circ \cdots \circ \mu_{z_1^*}(T_i) \quad \text{and} \quad I_w \oplus \Omega_w(R) = \mu_{q_1^*} \circ \cdots \circ \mu_{q_1^*}(V_i).$$

Besides $\Omega_w^{-1}(R)$, we can also compute $\Omega_w(R)$ by just knowing a sequence of mutations from $V_i$ to $R$. This works because $V_i$ and $T_i$ are connected via a known sequence of
mutations, namely $\mu_i$ if we start at $V_i$, and $\mu_i^{-1}$ if we start at $T_i$. The following picture illustrates the situation:

\[
\begin{array}{c}
\xymatrix{ W_1 \ar@{~>}[r]^{(\mu_i^{-1})^*} & V_1 \ar@{~>}[r]^{\mu_i} & T_1 \\
I_w \oplus \Omega_w(R) \ar[u]_-{\mu_2 \cdots \mu_1^*} & R \ar[u]_-{\mu_2 \cdots \mu_1^*} & I_w \oplus \Omega_w^{-1}(R) \ar[u]_-{\mu_2 \cdots \mu_1^*}
}\end{array}
\]

Proof. As before, for $1 \leq j \leq n$ set $p_j := \min\{1 \leq s \leq r \mid i_s = j\}$. Note that $p_j^{(t_j-1)} = p_{j_{\max}}$ and $p_j = p_{j_{\min}}$. In the following pictures we display only the relevant horizontal arrows. The quiver $\Gamma_{V_i}$ looks as follows:

\[
\begin{array}{c}
\xymatrix{ M[p_{1_{\max}}, p_1] \ar[r] & M[p_{1_{\max}}, p_{1\{1\}] \ar[r] & \cdots \ar[r] & M[p_{1_{\max}}, p_{1\{t_1-1\}]} \\
M[p_{n_{\max}}, p_n] \ar[r] & M[p_{n_{\max}}, p_{n\{1\}] \ar[r] & \cdots \ar[r] & M[p_{n_{\max}}, p_{n\{t_n-1\}]} 
}\end{array}
\]

Next, we display the quiver $\Gamma_{T_i}$:

\[
\begin{array}{c}
\xymatrix{ M[p_{1_{\max}}, p_1] \ar[r] & M[p_{1_{\max}}, p_{1\{1\}] \ar[r] & \cdots \ar[r] & M[p_{1_{\max}}, p_{1\{t_1-1\}]} \\
M[p_{n_{\max}}, p_n] \ar[r] & M[p_{n_{\max}}, p_{n\{1\}] \ar[r] & \cdots \ar[r] & M[p_{n_{\max}}, p_{n\{t_n-1\}]} 
}\end{array}
\]

We know that $I_w \oplus \Omega_w^{-1}(V_i) = T_i$. In particular, we have

$\Omega_w^{-1}(M[p_{j_{\{s-1\}}, p_j}) = M[p_{j_{\max}}, p_{j_{\{s\}}}]$

for all $1 \leq j \leq n$ and $1 \leq s \leq t_j - 1$. Thus $\Gamma_{T_i}$ looks like this:

\[
\begin{array}{c}
\xymatrix{ M[p_{1_{\{t_1-1\}}, p_1] \ar[r] & \Omega_w^{-1}(M[p_{1_{\{1\}}, p_1]) \ar[r] & \Omega_w^{-1}(M[p_{1_{\{1\}}, p_1)] \ar[r] & \cdots \ar[r] & \Omega_w^{-1}(M[p_{1_{\{t_1-2\}}, p_1]) \\
M[p_{n_{\{t_n-1\}}, p_n] \ar[r] & \Omega_w^{-1}(M[p_{n_{\{1\}}, p_n]) \ar[r] & \Omega_w^{-1}(M[p_{n_{\{1\}}, p_n]) \ar[r] & \cdots \ar[r] & \Omega_w^{-1}(M[p_{n_{\{t_n-2\}}, p_n]) 
}\end{array}
\]

The $n$ vertices of the form $M[p_{j_{\{t_j-1\}}, p_j]$ at the “left” of both quivers $\Gamma_{V_i}$ and $\Gamma_{T_i}$ are frozen vertices, to all other vertices we can apply the mutation operation.

Now let

$0 \to T_k \to T' \to T_k^* \to 0$

be an exchange sequence associated to the cluster algebra $\mathcal{R}(C_w, V_i)$. This yields an exchange triangle $T_k \to T' \to T_k^* \to T_k[1]$ in the stable category $C_w$. Note that $T_k[1] = \Omega_w^{-1}(T_k)$. It follows that $T_k[1] \to T'[1] \to T_k[1] \to T_k[2]$ is an exchange triangle as well. There is an associated exchange sequence

$0 \to \Omega_w^{-1}(T_k) \to I \oplus \Omega_w^{-1}(T') \to \Omega_w^{-1}(T_k^*) \to 0$
where $I$ is some module in $\text{add}(I_w)$. Thus, if we mutate the basic $C_w$-maximal rigid module $I_w \oplus \Omega^{-1}_w(T)$ in direction $\Omega^{-1}_w(T_k)$, we obtain $(\Omega^{-1}_w(T_k))^* = \Omega^{-1}_w(T_k^*)$. We argue similarly to show that the mutation of $I_w \oplus \Omega_w(T)$ in direction $\Omega_w(T_k)$ gives $(\Omega_w(T_k))^* = \Omega_w(T_k^*)$. This finishes the proof.

**Corollary 13.5.** If a $\Lambda$-module $R$ is $V_i$-reachable, then $\Omega^z_w(R)$ is $V_i$-reachable for all $z \in \mathbb{Z}$.

13.4. **Example.** Let $Q$ be a quiver with underlying graph $1 \rightarrow 2 \rightarrow 3 \rightarrow 4$ and let $i := (i_{10}, \ldots, i_1) := (1, 2, 1, 3, 2, 1, 4, 3, 2, 1)$. Then we get

\[ \Gamma_{V_i} \]

\[ \Gamma_{T_i} \]

Again, we identify the vertices of $\Gamma_{V_i}$ and $\Gamma_{T_i}$ with the indecomposable direct summands of $V_i$ and $T_i$, respectively. As before, we identify $\Gamma_{V_i}$ and the quiver $\Gamma_i$, which looks as follows:

\[ \Gamma_i \ (\cong \Gamma_{V_i}) \]

We have
\[
\mu_i = \mu_{10} \circ \cdots \circ \mu_2 \circ \mu_1 = (\text{id}) \circ (\text{id}) \circ (\mu_1) \circ (\mu_2) \circ (\mu_5 \circ \mu_1) \circ (\text{id}) \circ (\mu_3) \circ (\mu_6 \circ \mu_2) \circ (\mu_8 \circ \mu_5 \circ \mu_1).
\]
Mutation of $V_i$ at $V_5$ yields the following quiver:

The associated exchange sequences are

$$0 \rightarrow (1_2 3) \rightarrow 1 \oplus (1_2 3) \rightarrow (1_2) \rightarrow 0 \quad \text{and} \quad 0 \rightarrow (1_2) \rightarrow (1_2 \oplus (1_2 3) \rightarrow (1_2 3) \rightarrow 0$$

Next, we mutate at $V_6$. The exchange sequences looks as follows:

$$0 \rightarrow (1_2 3 4) \rightarrow (1_2 3) \oplus (1_2 3 4) \rightarrow (1_2 3) \rightarrow 0$$

and

$$0 \rightarrow (1_2 3) \rightarrow (1_2 3) \oplus (1_2 3 4) \rightarrow (1_2 3 4) \rightarrow 0$$

Set $R := (\mu_6 \circ \mu_5)(V_i)$. Thus we have $R = R_5 \oplus R_6 \oplus V_i/(V_5 \oplus V_6)$ with

$$R_5 = 1_2 3 \quad \text{and} \quad R_6 = 1_2 3 4.$$ 

To calculate $\Omega_w^{-1}(R)$, we have to compute $(\mu_6 \circ \mu_5^\ast)(T_i)$. Mutation of $T_i$ at $5^\ast = 5$ yields the following quiver:

The associated exchange sequences are

$$0 \rightarrow 2 \rightarrow 3 \rightarrow 4 \rightarrow 3 \rightarrow 4 \rightarrow 0 \quad \text{and} \quad 0 \rightarrow 3 \rightarrow 4 \rightarrow 2 \rightarrow 3 \rightarrow 4 \rightarrow 0.$$ 

Next, we mutate at $6^\ast = 2$. The exchange sequences looks as follows:

$$0 \rightarrow 2 \rightarrow 3 \rightarrow 4 \rightarrow 3 \rightarrow 4 \rightarrow 0 \quad \text{and} \quad 0 \rightarrow 3 \rightarrow 2 \rightarrow 3 \rightarrow 4 \rightarrow 2 \rightarrow 0.$$
We get \( \Omega_w^{-1}(R) := \Omega_w^{-1}(R_5) \oplus \Omega_w^{-1}(R_6) \oplus T_i/(T_5 \oplus T_6) \) with
\[
\Omega_w^{-1}(R_5) = 2 \quad \text{and} \quad \Omega_w^{-1}(R_6) = 2.
\]

### 14. Irreducible Components Associated to \( C_w \)

#### 14.1. Module varieties.

Let \( \Gamma := (\Gamma_0, \Gamma_1, s, t) \) be a finite quiver with vertex set \( \Gamma_0 = \{1, \ldots, r\} \), arrow set \( \Gamma_1 \) and maps \( s, t : \Gamma_1 \to \Gamma_0 \) which map an arrow \( a \) to its start vertex \( s(a) \) and its terminal vertex \( t(a) \), respectively. In this section, we interpret dimension vectors \( f = (f_1, \ldots, f_r) \) for \( \Gamma \) as maps \( f : \Gamma_0 \to \mathbb{N} \). We consider the affine space
\[
\text{mod}(\mathbb{C}\Gamma, f) = \text{rep}(\Gamma, f) = \prod_{a \in \Gamma_1} \mathbb{C}^{f(t(a)) \times f(s(a))}
\]
of representations of \( \Gamma \) with dimension vector \( f \). Here \( \mathbb{C}^{p \times q} \) denotes the vector space of \((p \times q)\)-matrices with entries in \( \mathbb{C} \). This coincides with our definitions in Section 2.1 except that we now work with spaces \( \mathbb{C}^{p \times q} \) of matrices rather than spaces \( \text{Hom}_\mathbb{C}(\mathbb{C}^q, \mathbb{C}^p) \) of linear maps. So each element in \( \text{mod}(\mathbb{C}\Gamma, f) \) is of the form \( M = (M(a))_{a \in \Gamma_1} \) where \( M(a) \) is a matrix of size \( f(t(a)) \times f(s(a)) \).

The group
\[
\text{GL}_f := \prod_{i \in \Gamma_0} \text{GL}_{f(i)}(\mathbb{C})
\]
acts from the left by conjugation on \( \text{mod}(\mathbb{C}\Gamma, f) \), i.e. for \( M = (M(a))_{a \in \Gamma_1} \in \text{mod}(\mathbb{C}\Gamma, f) \) and \( g = (g(i))_{i \in \Gamma_0} \in \text{GL}_f \) we have
\[
(g.M)(a) = g(t(a))M(a)g(s(a))^{-1}
\]
for all \( a \in \Gamma_1 \). The orbits of \( \text{GL}_f \) on \( \text{mod}(\mathbb{C}\Gamma, f) \) correspond to the set of isomorphism classes of \( \mathbb{C}\Gamma \)-modules with dimension vector \( f \). Given a path \( p = a_1 \cdots a_2 a_1 \) in \( \Gamma \) (i.e. \( a_1, \ldots, a_l \) are arrows with \( s(a_{i+1}) = t(a_i) \) for \( 1 \leq i \leq l-1 \)) we define
\[
M(p) := M(a_1) \cdots M(a_2)M(a_1)
\]
for any \( M \in \text{mod}(\mathbb{C}\Gamma, f) \). More generally, for any element \( \rho \in e_j \mathbb{C}\Gamma e_j \) we have \( M(\rho) \in \mathbb{C}^{f(i) \times f(j)} \), since \( \rho \) is a linear combination of paths from \( j \) to \( i \). (For \( k \in \Gamma_0 \) we denote the associated path of length 0 by \( e_k \).) Set \( s(\rho) := j \) and \( t(\rho) := i \). If \( I \subset \mathbb{C}\Gamma \) is a finitely generated ideal contained in the ideal generated by all paths of length 2, we may assume that it is generated by elements \( \rho_1, \ldots, \rho_q \) with \( \rho_k \in e_{t_k} \mathbb{C}\Gamma e_{s_k} \) for certain \( s_k, t_k \in \Gamma_0 \) where \( 1 \leq k \leq q \). Let \( A := \mathbb{C}\Gamma/I \). We consider the affine \( \text{GL}_f \)-variety
\[
\text{mod}(A, f) := \{ M \in \text{mod}(\mathbb{C}\Gamma, f) \mid M(\rho_k) = 0 \text{ for } 1 \leq k \leq q \}.
\]
Again, the \( \text{GL}_f \)-orbits correspond to the isomorphism classes of \( A \)-modules with dimension vector \( f \).

Given \( M \in \text{mod}(A, f) \) and \( M' \in \text{mod}(A, f') \) we identify any homomorphism \( \varphi \in \text{Hom}_A(M, M') \) with a family of matrices
\[
(\varphi(k))_{k \in \Gamma_0} \in \prod_{k \in \Gamma_0} \mathbb{C}^{f'(k) \times f(k)}
\]
such that
\[
\varphi(t(b))M(b) = M'(b)\varphi(s(b))
\]
for all $b \in \Gamma$. In other words, the diagram
\[
\begin{array}{ccc}
Cf(s(b)) & \xrightarrow{\phi(s(b))} & Cf'(s(b)) \\
M(b) & \downarrow & M'(b) \\
Cf(t(b)) & \xrightarrow{\phi(t(b))} & Cf'(t(b))
\end{array}
\]
commutes for all $b \in \Gamma$.

14.2. A stratification of $\Lambda^w_d$. Recall that for $X \in \text{nil}(\Lambda)$ we have $X \in C_w$ if and only if there is a (unique) filtration
\[0 = X_0 \subseteq X_1 \subseteq \cdots \subseteq X_r = X\]
by submodules such that $X_k/X_{k-1} \cong M^a_k$ for some $a_k \geq 0$ for all $1 \leq k \leq r$, see Proposition [10.2]. In this case, we have
\[\text{dim}_{B_i}(\text{Hom}_\Lambda(V_i, X)) = \sum_{k=1}^r a_k \text{dim}_{B_i}(\Delta_k),\]
i.e. $a := (a_1, \ldots, a_r)$ is the $\Delta$-dimension vector of $\text{Hom}_\Lambda(V_i, X)$. Thus, with
\[\mu(a) := \sum_{k=1}^r a_k \text{dim}_\Lambda(M_k)\]
we may consider
\[\Lambda^a := \{ X \in \Lambda_{\mu(a)} \mid X \text{ has a filtration } 0 = X_0 \subseteq X_1 \subseteq \cdots \subseteq X_r = X \text{ with } X_k/X_{k-1} \cong M^a_k, 1 \leq k \leq r \}.\]
In other words, $\Lambda^a = \{ X \in \Lambda_{\mu(a)} \mid X \in C_{M_i,a} \}$. Define
\[\Lambda^w_d := \{ X \in \Lambda_d \mid X \in C_w \}.
\]
We get a finite decomposition
\[\Lambda^w_d = \bigcup_{a \in \mathbb{N}^r, \mu(a) = d} \Lambda^a\]
into disjoint subsets.

**Lemma 14.1.** $\Lambda^a$ is an irreducible constructible subset of $\Lambda_{\mu(a)}$.

**Proof.** We know from Proposition [10.5] that $X \in \Lambda^a$ if and only if there exists a short exact sequence
\[0 \rightarrow \bigoplus_{k=1}^r V^a_{k-} \rightarrow \bigoplus_{k=1}^r V^a_k \rightarrow X \rightarrow 0\]
with $V^*_k = 0$ if $k^- = 0$. Now the result follows from [Bo] Section 2.1. \qed

**Remark 14.2.** It is not hard to see that for $X \in \text{nil}(\Lambda)$ the following are equivalent
\[\begin{align*}
&\text{(i) } X \in C_w; \\
&\text{(ii) } \text{Hom}_\Lambda(D(J_w), X) = 0 = \text{Ext}_\Lambda^1(D(\Lambda/J_w), X).
\end{align*}\]
Here $J_i$ is by definition the ideal of $\Lambda$ which is as a $\mathbb{C}$-vector space generated by all paths $p$ in $Q$ with $p \neq e_i$, and we set $J_w := J_{i_r} \cdots J_{i_1}$. It follows that $\Lambda^w_d$ is an open subset in $\Lambda_d$ and it follows that $\Lambda^a$ is a locally closed subset of $\Lambda_{\mu(a)}$. However, we will not need this fact.
14.3. Review of Bongartz’s bundle construction. Following Bongartz [Bo, Section 4], we apply the above definitions and conventions in order to relate the varieties $\Lambda^a$ and $\text{mod}(B_1, f)$. Assume that

$$f = \sum_{k=1}^{r} a_k \dim_{B_1}(\Delta_k).$$

Recall that this implies $\dim \text{Hom}_\Lambda(V_k, X) = f(k)$ for all $X \in \Lambda^a$. It follows, that

$$\{(X, \varphi) \mid X \in \Lambda^a \text{ and } \varphi \in \text{Hom}_\Lambda(V_k, X)\}$$

is a (usually non-trivial) algebraic vector bundle of rank $f(k)$ over $\Lambda^a$. Thus, setting

$$I(f) := \{(i, j) \in \mathbb{N}_1^2 \mid 1 \leq i \leq r \text{ and } 1 \leq j \leq f(i)\}$$

we consider

$$H^a := \{(X, (\varphi_j^{(k)})_{(i, j) \in I(f)}) \mid X \in \Lambda^a \text{ and } (\varphi_1^{(k)}, \ldots, \varphi_{f(k)}) \text{ is a basis of } \text{Hom}_\Lambda(V_k, X), 1 \leq k \leq r\}$$

equipped with a left $\text{GL}_d$-action given by

$$g.(X, (\varphi_j^{(k)})_{(i, j) \in I(f)}) = (g.X, (g \circ \varphi_j^{(k)})_{(i, j) \in I(f)}),$$

and with a right $\text{GL}_r$-action given by

$$(X, (\varphi_j^{(k)})_{(i, j) \in I(f)}).h = (X, (\sum_{t=1}^{f(k)} \varphi_t^{(k)} h_{t,j}(k))_{(i, j) \in I(f)}).$$

Here $h_{t,j}(k)$ denotes the entry in row $t$ and column $j$ of the matrix $h_k$. Clearly, the map

$$\pi_1: H^a \rightarrow \Lambda^a$$

defined by

$$(X, (\varphi_j^{(k)})_{(i, j) \in I(f)}) \mapsto X$$

is a $\text{GL}_d$-equivariant $\text{GL}_r$-principal bundle.

In order to define a map $\pi_2: H^a \rightarrow \text{mod}(B_1, f)$ we write $B_1 = C\Gamma/I$ for an admissible ideal $I$, and we identify the vertices $\Gamma_0 = \{1, 2, \ldots, r\}$ with the summands $V_1, \ldots, V_r$ of $V_i$. Recall that $\Gamma \equiv \Gamma_1$. Thus we may think of each arrow $b: i \rightarrow j$ in $\Gamma_1$ as a certain element $b \in \text{Hom}_\Lambda(V_j, V_i)$. With these identifications

$$\pi_2(X, (\varphi_j^{(k)})_{(i, j) \in I(f)}) = (M(b))_{b \in \Gamma_1}$$

is determined by

$$\varphi_j^{(s(b))} \circ b = \sum_{u=1}^{r(\ell(b))} \varphi_u^{(\ell(b))} M_{u,j}(b).$$

Here $M_{u,j}(b)$ denotes the entry in row $u$ and column $j$ of the matrix $M(b)$. It is easy to verify that $\pi_2$ is a $\text{GL}_d$-equivariant $\text{GL}_r$-equivariant morphism, if we view $\text{mod}(B_1, f)$ with the right $\text{GL}_r$-action induced from the usual left action via the anti-automorphism $h \mapsto h^{-1}$ of $\text{GL}_r$. Moreover, by construction

$$\pi_2(X, (\varphi_j^{(k)})_{(i, j) \in I(f)}) \cong \text{Hom}_\Lambda(V_i, X)$$
as a $B_1$-module. Thus, in fact $\text{Im}(\pi_2) = \mathcal{F}(\Delta, f)$, where $\mathcal{F}(\Delta, f)$ is the subset of $\text{mod}(B_1, f)$ consisting of the $\Delta$-filtered $B_1$-modules with dimension vector $f$. It is shown in [CBS Corollary 1.5] that $\mathcal{F}(\Delta, f)$ is open in $\text{mod}(B_1, f)$. Since $\pi_1$ is a $\text{GL}_r$-principal bundle it follows from Lemma [14.1] that $\mathcal{F}(\Delta, f) = \pi_2(\pi_1^{-1}(\Lambda^a))$ is also irreducible. In particular, $\mathcal{F}(\Delta, f)$ is an irreducible component of $\text{mod}(B_1, f)$. 
Finally, for $\pi_2(X, (\varphi_j^{(k)})_{(k,j) \in I(f)}) = M$ we have
\[
\dim \text{GL}_d . X = \dim \text{GL}_d - \dim \text{End}_\Lambda(X)
\]
\[
\dim \pi_1^{-1}(\text{GL}_d . X) = \dim \text{GL}_d - \dim \text{End}_\Lambda(X) + \dim \text{GL}_f
\]
\[
\dim (\text{GL}_f . M) = \dim \text{GL}_f - \dim \text{End}_\Lambda(X).
\]
The last equation holds, since the functor $F_1: C_w \to \mathcal{F}(\Delta)$ which maps $X$ to $\text{Hom}_\Lambda(V_1, X)$ is an equivalence of additive categories. By the same token $\pi_2^{-1}(M, \text{GL}_f) = \pi_1^{-1}(\text{GL}_d . X)$. We conclude $\dim \pi_2^{-1}(M) = \dim \text{GL}_d$. Thus we proved the following:

**Lemma 14.3.** For $a \in \mathbb{N}^r$ and
\[
f = \sum_{k=1}^{r} a_k \dim_{B_1}(\Delta_k)
\]
there exists a variety $H^a$ with a $\text{GL}_d$-$\text{GL}_f$-action together with two surjective morphisms
\[
\begin{array}{c}
\Lambda^a \\
\pi_1 \downarrow \quad \pi_2 \\
H^a \downarrow \quad \mathcal{F}(\Delta, f)
\end{array}
\]
such that $\pi_1$ is a $\text{GL}_d$-equivariant $\text{GL}_f$-principal bundle, and $\pi_2$ is a $\text{GL}_f$-equivariant and $\text{GL}_d$-invariant morphism. Moreover, $\dim \pi_2^{-1}(M) = \dim \text{GL}_d$ for all $M \in \mathcal{F}(\Delta, f)$.

Since $C_w = \text{Fac}(V_1)$, it is easy to see that for $g \in \text{GL}_d$ and $h \in H^a$ with $gh = h$ we have $g = 1_{\text{GL}_d}$.

**Remark 14.4.** It seems plausible that with a dual bundle construction, as in [Bo, 4.3], one can show that $\pi_2$ is a $\text{GL}_d$-principal bundle.

### 14.4. Parametrization of components.

**Lemma 14.5.** For $a = (a_1, \ldots, a_r)$, $d = \mu(a)$ and $f = \sum_{k=1}^{r} a_k \dim_{B_1}(\Delta_k)$ we have
\[
\dim \mathcal{F}(\Delta, f) = \dim \text{GL}_f - (d, d)_Q.
\]

**Proof.** For any $N \in \mathcal{F}(\Delta, f)$ we have $\text{proj. dim}_{B_1}(N) \leq 1$, thus $\text{Ext}_{B_1}^2(N, N) = 0$, which implies that $N$ is a smooth point of the scheme $\text{mod}(B_1, f)$. Recall that $\mu(a) = \sum_{k=1}^{r} a_k \dim(M_k)$. Now Voigt’s Lemma [Ga, 1.3] and our Lemma 11.4 allow the calculation
\[
\dim \mathcal{F}(\Delta, f) = \dim \text{GL}_f . N + \dim \text{Ext}_{B_1}^1(N, N)
\]
\[
= \dim \text{GL}_f - (f, f)_{B_1}
\]
\[
= \dim \text{GL}_f - \left( \sum_{k=1}^{r} a_k^2 \langle \Delta_k, \Delta_k \rangle_{B_1} + \sum_{1 \leq s < k \leq r} a_k a_s \langle \Delta_k, \Delta_s \rangle_{B_1} \right)
\]
\[
= \dim \text{GL}_f - \left( \sum_{k=1}^{r} a_k^2 \langle M_k, M_k \rangle_Q + \sum_{1 \leq s < k \leq r} a_k a_s \langle M_k, M_s \rangle_Q \right)
\]
\[
= \dim \text{GL}_f - (d, d)_Q.
\]
For the fourth equality we used Lemma 11.4 and the fact that
\[
\langle \Delta_k, \Delta_k \rangle_{B_1} = 1 = \langle M_k, M_k \rangle_Q.
\]
This finishes the proof. □
Proposition 14.6. The (Zariski-) closure $Z^a$ of $\Lambda^a$ is an irreducible component of $\Lambda_{\mu(a)}$. In particular, $Z^a$ is the unique irreducible component of $\Lambda_{\mu(a)}$ which contains a dense open subset which belongs to $\Lambda^a$.

Proof. We know from Lemma [14.1] that $\Lambda^a$ is an irreducible constructible subset of $\Lambda_{\mu(a)}$. Thus, $Z^a$ is an irreducible subvariety of $\Lambda_{\mu(a)}$. Since $\Lambda_{\mu(a)}$ is equi-dimensional, it remains to show that

$$\dim \Lambda^a = \dim \text{GL}_d - \langle d, d \rangle_Q = \dim \Lambda_d.$$ 

Recall that $d = \mu(a)$ and

$$f = \sum_{k=1}^{r} a_k \dim_{F_k}(\Delta_k).$$

As before, $F(\Delta, f)$ denotes the irreducible open subset of $\Delta$-good modules in the affine $GL_f$-variety $\text{mod}(B_1, f)$ of $B_1$-modules with dimension vector $f$. By Lemma [14.5] we know that

$$\dim F(\Delta, f) = \dim \text{GL}_f - \langle d, d \rangle_Q.$$ 

In Section [14.3] we constructed a $GL_d$-$GL_f$-variety $H^a$ together with surjective morphisms

$$\begin{array}{ccc}
H^a & \rightarrow & F(\Delta, f) \\
\pi_1 & \rightarrow & \Lambda^a \\
\pi_2 & \rightarrow &
\end{array}$$

with $\pi_1$ a $GL_d$-equivariant $GL_f$-principal bundle, and $\pi_2$ a $GL_f$-equivariant morphism with all fibers having the same dimension as $GL_d$. Our claim about the dimension of $\Lambda^a$ follows.

Let $M = M_{\delta}^{a_1} \oplus \cdots \oplus M_{\delta}^{a_r}$ for some $a = (a_1, \ldots, a_r) \in \mathbb{N}^r$. We just proved that $Z^a$ is an irreducible component of $\Lambda_{\mu(a)}$. Let us denote the corresponding dual semicanonical basis vector $\rho Z^a$ by $s_M$. Thus there is a dense open subset $U^a \subseteq Z^a$ such that $s_M = \delta_X$ for all $X \in U^a$.

15. A dual PBW-basis and a dual semicanonical basis for $\mathcal{A}(C_w)$

In this section we prove Theorem [3.1] and Theorem [3.2]. We also deduce from these results the existence of semicanonical bases for the cluster algebras $\tilde{R}(C_w, T)$ and $\tilde{R}(C_w, T')$ obtained by inverting and specializing coefficients, respectively.

15.1. Proof of Theorem [3.1]. By the definition of the cluster algebra $\mathcal{A}(C_w, T)$, its initial seed is $(y, B(T)^\circ)$ where $y = (y_1, \ldots, y_r)$. In particular, $\mathcal{A}(C_w, T)$ is a subalgebra of $\mathcal{F} := \mathbb{C}(y_1, \ldots, y_r)$. Since $T$ is rigid, by Theorem [2.6] and [GLS1] Theorem 1.1] every monomial in the $\delta_{T_k}$ belongs to the dual semicanonical basis $S^a$, hence the $\delta_{T_k}$ are algebraically independent, and $(\delta_{T_1}, \ldots, \delta_{T_r})$ is a transcendence basis of the subfield $\mathcal{G}$ it generates inside the fraction field of $U(n)_{\delta, T}$. Let $\iota : \mathcal{F} \rightarrow \mathcal{G}$ be the field isomorphism defined by $\iota(y_k) = \delta_{T_k}$ where $1 \leq k \leq r$. Combining Theorems [2.7] and [2.20] we see that the cluster variable $z$ of $\mathcal{A}(C_w, T)$ obtained from the initial seed $(y, B(T)^\circ)$ through a sequence of seed mutations in successive directions $k_1, \ldots, k_s$ will be mapped by $\iota$ to $\delta_X$, where $X \in C_w$ is the indecomposable rigid module obtained by the same sequence of mutations of rigid modules. It follows that $\iota$ restricts to an isomorphism from $\mathcal{A}(C_w, T)$ to $\mathcal{R}(C_w, T)$. This isomorphism is completely determined by the images of the elements $y_k$, hence the unicity. The cluster monomials are mapped to elements $\delta_R$ where $R$ is a (not necessarily $C_w$-maximal or basic)
rigid module in $C_w$, hence an element of $S^*$. More precisely, the cluster monomials in $\mathcal{R}(C_w, T)$ are the elements $\delta_R$, where $R$ runs through the set of all $T$-reachable modules (see Section 3.1 for the definition of $T$-reachable). This finishes the proof of Theorem 3.1.

15.2. Proof of Theorem 3.2. Let $M_i = M_1 \oplus \cdots \oplus M_r$ be as before. For $1 \leq k \leq r$ we proved that $\dim(M_k) = \beta_i(k)$. Set $\beta(k) := \beta_i(k)$.

We have

$$\mathbb{C}[\delta_{M_1}, \ldots, \delta_{M_r}] \subseteq \mathcal{R}(C_w, V_i) \subseteq \text{Span}_\mathbb{C}\langle \delta_X \mid X \in C_w \rangle,$$

where the first inclusion follows from the observation that each of the $\Lambda$-modules $M_k$ for $1 \leq k \leq r$ is the direct summand of a $C_w$-maximal rigid module on the mutation path from $V_i$ to $T_i$, see Section 13. The second inclusion follows from the observation that $\text{Span}_\mathbb{C}\langle \delta_X \mid X \in C_w \rangle$ is an algebra. This follows from the fact that $C_w$ is an additive category together with Theorem 2.6.

For each $M \in \text{add}(M_i)$ we constructed a dual semicanonical basis vector $s_M$, see the explanation at the end of Section 14.4. If $M = M_k$ is an indecomposable direct summand of $M_i$, then $s_M = \delta_{M_k}$. (For every rigid $\Lambda$-module $R \in \text{nil}(\Lambda)$, the function $\delta_R$ belongs to the dual semicanonical basis. The modules $M_k$ are rigid by Corollary 9.9.)

The following theorem is a slightly more explicit statement of Theorem 3.2:

Theorem 15.1. Let $w$ be a Weyl group element, and let $i = (i_r, \ldots, i_1)$ be a reduced expression of $w$. Then the following hold:

(i) We have

$$\mathcal{R}(C_w, V_i) = \mathbb{C}[\delta_{M_1}, \ldots, \delta_{M_r}] = \text{Span}_\mathbb{C}\langle \delta_X \mid X \in C_w \rangle;$$

(ii) The set

$$\{\delta_M \mid M \in \text{add}(M_i)\}$$

is a $\mathbb{C}$-basis of $\mathcal{R}(C_w, V_i)$;

(iii) The subset

$$S^*_w := \{s_M \mid M \in \text{add}(M_i)\}$$

of the dual semicanonical basis is a $\mathbb{C}$-basis of $\mathcal{R}(C_w, V_i)$, and all cluster monomials of $\mathcal{R}(C_w, V_i)$ belong to $S^*_w$.

The basis $\{\delta_M \mid M \in \text{add}(M_i)\}$ will be called dual PBW-basis of $\mathcal{R}(C_w, V_i)$, and $S^*_w$ the dual semicanonical basis of $\mathcal{R}(C_w, V_i)$. The proof of this theorem will be given after a series of lemmas.

Let

$$n = \bigoplus_{d \in \Delta^+} n_d$$

be the root space decomposition of $n$. We consider $n$ as a subspace of the universal enveloping algebra $U(n)$. Since we identify $U(n)$ and $\mathcal{M}$, we can think of an element $f$ in $n_d$ as a constructible function $f : \Lambda_d \to \mathbb{C}$ in $\mathcal{M}_d$.

Lemma 15.2. Let $f \in n_d$. If $d \not\in \{\beta(k) \mid 1 \leq k \leq r\}$, then

$$f(X) = 0 \text{ for all } X \in C_w.$$
Proof. Let \( X \in \mathcal{C}_w \), and let \( f \in \mathfrak{n}_d \) with \( f(X) \neq 0 \). In particular, \( f \in \mathcal{M}_d \), and we have \( d = \dim(X) \in \Delta^+ \). We know that \( X \in \mathcal{C}_{M, a} \) for some \( a = (a_1, \ldots, a_r) \). Thus

\[
\dim(X) = \sum_{k=1}^r a_k \dim(M_k).
\]

By Lemma 4.2, \( \Delta^+_s = \{ \beta(k) \mid 1 \leq k \leq r \} \) is a bracket closed subset of \( \Delta^+ \). Thus \( d = \beta(s) \) for some \( 1 \leq s \leq r \). This finishes the proof. \( \square \)

As before, let \( i = (i_r, \ldots, i_1) \) be a reduced expression of a Weyl group element \( w \), and let

\[
\mathcal{P} = \left\{ p_m \mid m \in \mathbb{N}^{(j)} \right\}
\]

be an \( i \)-compatible PBW-basis of \( U(\mathfrak{n}) \), see Sections 4.2 and 4.3.

**Lemma 15.3.** Let \( p_m \in \mathcal{P} \) where \( m = (m_j)_{j \in J} \). If \( m_j > 0 \) for some \( j > r \), then

\[
p_m(X) = 0 \quad \text{for all} \quad X \in \mathcal{C}_w.
\]

Equivalently, \( \delta_X(p_m) = 0 \) for all \( X \in \mathcal{C}_w \).

**Proof.** We regard \( p_m \) as an element of \( \mathcal{M} \), hence as a convolution product

\[
p_m = p_1^{(m_1)} * p_2^{(m_2)} * \cdots * p_s^{(m_s)}.
\]

Let us assume that \( s > r \) and \( m_s > 0 \). It follows that \( p_m = p * p_s \) where

\[
p := \frac{1}{m_s} \left( p_1^{(m_1)} * p_2^{(m_2)} * \cdots * p_s^{(m_s-1)} * p_{s-1}^{(m_s-1)} \right).
\]

Now let \( X \in \mathcal{C}_w \). Then

\[
p_m(X) = (p * p_s)(X) = \sum_{m \in \mathbb{C}} m \chi_c(\{ U \subseteq X \mid p(U)p_s(X/U) = m \}).
\]

Since \( \mathcal{C}_w \) is closed under factor modules, we get \( X/U \in \mathcal{C}_w \) for all submodules \( U \) of \( X \). Now Lemma 4.2 yields \( p_s(X/U) = 0 \) for all such \( U \). Thus we proved that \( p_m(X) = 0 \) for all \( X \in \mathcal{C}_w \). \( \square \)

Recall from Section 4.3 that

\[
\mathcal{P}_i^* = \left\{ (p_1^*)^{m_1} \cdots (p_r^*)^{m_r} \mid m_k \geq 0 \text{ for all } 1 \leq k \leq r \right\}
\]

is a subset of the dual PBW-basis \( \mathcal{P}_i^* \) of \( U(\mathfrak{n})_{gr}^* \). The following lemma is of central importance:

**Lemma 15.4.** For \( 1 \leq k \leq r \) we have \( p_k^* = \delta_{M_k} \) (up to rescaling of \( p_k \)).

**Proof.** For each \( 1 \leq k \leq r \) there exists some \( m = (m_i)_{i \geq 1} \) such that \( p_m(M_k) \neq 0 \), since \( \delta_{M_k} \in \mathcal{M}^* \equiv U(\mathfrak{n})_{gr}^* \) is a linear combination of elements in \( \mathcal{P}_i^* \). Let \( s \) be the natural number with \( m_s \geq 1 \), but \( m_j = 0 \) for all \( j > s \).

By Lemma 15.3 if \( s > r \), then \( p_m(X) = 0 \) for all modules \( X \in \mathcal{C}_w \), a contradiction. Thus, we know that \( s \leq r \). We even know that \( s \leq k \), since \( M_k \) is an object of the subcategory \( \mathcal{C}_u \) of \( \mathcal{C}_w \), where \( u = s_{i_k} \cdots s_{i_2} s_{i_1} \).

If \( s = k \), then for dimension reasons \( m_1 = \cdots = m_{k-1} = 0 \) and \( m_k = 1 \). So we get \( p_m = p_k \).

Finally, assume \( s < k \). Since \( p_m(M_k) \neq 0 \), we know that \( M_k \) has a filtration

\[
0 = U_{1,0} \subseteq U_{1,1} \subseteq \cdots \subseteq U_{1,m_1} = U_{2,0} \subseteq U_{2,1} \subseteq \cdots \subseteq U_{2,m_2} = U_{3,0} \subseteq \cdots \subseteq U_{s,m_s} = M_k
\]

The following lemma is of central importance:
such that \( p_i(U_{i,j}/U_{i,j-1}) \neq 0 \) for all \( 1 \leq i \leq s \) and \( 1 \leq j \leq m_i \). But we know that \( p_i \) lies in \( M_{\beta(i)} \). In other words, we have \( \dim(U_{i,j}/U_{i,j-1}) = \beta(i) \). This implies that \( \beta(k) \), the dimension vector of \( M_k \), is a positive integer linear combination of \( \beta(i) \)'s with \( i < k \). More precisely,

\[
\beta(k) = m_1\beta(1) + \cdots + m_s\beta(s).
\]

But \( \beta(1), \ldots, \beta(s) \) belong to the bracket closed set \( \Delta^+_w \) where \( v := s_{i_s} \cdots s_{i_2}s_{i_1} \). Thus \( \beta(k) \) is also in \( \Delta^+_w \), which is a contradiction, since \( s < k \).

Summarizing, we proved that \( p_m(M_k) \neq 0 \) if and only if \( p_m = p_k \). Now we can rescale our PBW-basis elements \( p_k \), and we obtain without loss of generality that \( p_k(M_k) = 1 \). Thus we proved that

\[
\delta_{M_k}(p_m) := p_m(M_k) = \begin{cases} 1 & \text{if } p_m = p_k, \\ 0 & \text{otherwise}. \end{cases}
\]

In other words, \( \delta_{M_k} = p_k^* \).

**Corollary 15.5.** Under the identification \( U(n)^*_{\text{gr}} \cong M^* \) we have

\[
P_1^* = \{ \delta_M \mid M \in \text{add}(M_1) \}.
\]

**Proof.** By definition

\[
P_1^* = \{ (p_1)^{m_1} \cdots (p_r)^{m_r} \mid m_k \geq 0 \text{ for all } 1 \leq k \leq r \} \subseteq P^*.
\]

This implies the result, since \( p_k^* = \delta_{M_k} \) and \( \delta_X \cdot \delta_Y = \delta_{X \oplus Y} \) for all nilpotent \( \Lambda \)-modules \( X \) and \( Y \). \(\square\)

**Proof of Theorem 15.7.** Let \( X \in C_w \). By Lemma 15.3 and Corollary 15.5 \( \delta_X \) is a linear combination of dual PBW-basis vectors of the form \( \delta_M \) with \( M \in \text{add}(M_1) \). Hence \( \delta_X \in \mathbb{C}[\delta_{M_1}, \ldots, \delta_{M_r}] \), and

\[
\text{Span}_\mathbb{C}(\delta_X \mid X \in C_w) \subseteq \mathbb{C}[\delta_{M_1}, \ldots, \delta_{M_r}] \subseteq \mathcal{R}(C_w, V_1).
\]

Using the known reverse inclusions we get (i) and (ii) of Theorem 15.1.

Next, let \( M = M_1^{a_1} \oplus \cdots \oplus M_r^{a_r} \) be a module in \( \text{add}(M_1) \). Set \( a := (a_1, \ldots, a_r) \). Then \( s_M = \delta_X \) for some module \( X \in \mathbb{Z}^a \). In particular, \( X \) is contained in \( C_w \). Thus, by what we proved up to now we get

\[
s_M = \delta_X \in \mathcal{R}(C_w, V_1).
\]

For dimension reasons this implies that

\[
S_w^* := \{ s_M \mid M \in \text{add}(M_1) \} = S^* \cap \mathcal{R}(C_w, V_1)
\]

is a \( \mathbb{C} \)-basis of \( \mathcal{R}(C_w, V_1) \). By what we proved before, the set of cluster monomials of \( \mathcal{R}(C_w, V_1) \) are a subset of \( S_w^* \). This finishes the proof of Theorem 15.1. \(\square\)

By Theorem 15.1, we know that

\[
\mathcal{R}(C_w, V_1) = \mathbb{C}[p_1^*, \ldots, p_r^*].
\]

Thus Proposition 8.2 yields the following result:

**Proposition 15.6.** Under the identification \( U(n)^*_{\text{gr}} \cong \mathbb{C}[N] \) the cluster algebra \( \mathcal{R}(C_w, V_1) \) gets identified to the ring of invariants \( \mathbb{C}[N]^{N(w)} \), which is isomorphic to \( \mathbb{C}[N(w)] \).

**Corollary 15.7.** Let \( i = (i_r, \ldots, i_1) \) be a reduced expression of \( w \). For \( X \in C_w \), the function \( \varphi_X \in \mathbb{C}[N] \) is determined by its values on \( \{ x_i(t) \mid t = (t_r, \ldots, t_1) \in (\mathbb{C}^*)^r \} \) where \( x_i(t) := x_{i_r}(t_r) \cdots x_{i_2}(t_2)x_{i_1}(t_1) \).
Proof. Let \( \varphi, \psi \in \mathbb{C}[N]\mathbb{C}(w) \). Then \( \varphi = \psi \) if and only if \( \varphi(x(t)) = \psi(x(t)) \) for all \( t \in (\mathbb{C}^*)^r \): Recall that each \( x \in N \) can be written as \( x = yy' \) for a unique \( (y, y') \in N(w) \times N(w) \). For \( x \in N(w) \) we have \( \pi_w(x) = y \). Furthermore, the image of \( \pi_w \) is dense in \( N(w) \), see Proposition [5.5]. It is well known that the set \( \{x(t) \mid t \in (\mathbb{C}^*)^r\} \) contains a dense open subset of \( N(w) \). For \( x = x(t) \) we get
\[
\varphi(\pi_w(x)) = \varphi(y) = \varphi(yy') = \varphi(x).
\]
For the second equality we used that \( \varphi \) is \( N'(w) \)-invariant. Since \( \varphi \) is a regular function, its values on the whole of \( N(w) \) are already determined by its values on \( \pi_w(x(t)), t \in (\mathbb{C}^*)^r \).

15.3. Proof of Theorem [3.3]. By Proposition [8.5] we know that \( \mathbb{C}[N(w)] \) is the localization of the ring \( \mathbb{C}[N(w)] \) with respect to the minors \( D_{\omega_i, w^{-1}(\omega_i)} \). By Proposition [15.6] \( \mathbb{C}[N(w)] \) is equal to the cluster algebra \( \mathcal{R}(C_w, V_1) \). By Proposition [9.1] the minors \( D_{\omega_i, w^{-1}(\omega_i)} \) coincide with the functions \( \varphi_X \) where \( X \) runs through the set of indecomposable \( C_w \)-projective-injectives. In other words, the \( D_{\omega_i, w^{-1}(\omega_i)} \) coincide with the generators of the coefficient ring of \( \mathcal{R}(C_w, V_1) \). Hence \( \mathbb{C}[N(w)] \) is equal to the cluster algebra \( \mathcal{R}(C_w, V_1) \).

15.4. Example. Let us discuss an example of base change between \( \mathcal{P}_1^* \) and \( \mathcal{S}_w^* \). Let \( Q \) be a quiver with underlying graph \( 1 \rightarrow 2 \rightarrow 3 \) and let \( \mathbf{i} := (i_0, \ldots, i_1) := (2, 3, 1, 2, 3, 1) \), which is a reduced expression of the Weyl group element \( w := s_2s_3s_1s_2s_3s_1 \). As before, let \( V_1 = V_1 \oplus \cdots \oplus V_6 \) and \( M_1 = M_1 \oplus \cdots \oplus M_6 \), where as always \( M_k = M[k, k] \). The \( \Lambda \)-modules \( V_k \) are the following:
\[
\begin{align*}
V_1 &= M_1 = 1 & V_2 &= M_2 = 3 & V_3 &= M_3 = 1^23^1 \\
V_4 &= M[4, 1] &= 2^13^3 & V_5 &= M[5, 2] &= 1^23^2 & V_6 &= M[6, 3] &= 1^23^2.
\end{align*}
\]
The initial cluster of our cluster algebra \( \mathcal{R}(C_w, V_1) \) looks as follows:

\[
\begin{array}{c}
V_4 & \rightarrow & V_1 \\
V_6 & \rightarrow & V_3 \\
V_5 & \rightarrow & V_2
\end{array} =
\begin{array}{c}
1^23 & \rightarrow & 1 \\
1^23 & \rightarrow & 1
\end{array}
\]

We have
\[
M_4 = 2^3 \quad M_5 = 1^2 \quad M_6 = 2.
\]
There are only three more indecomposable \( \Lambda \)-modules, namely
\[
W_1 = 2^3 \quad W_2 = 1^2 \quad W_3 = 1^23^2.
\]
Observe that \( \Omega(V_k) = W_k \) for \( 1 \leq k \leq 3 \).

The functions \( \delta_{M_k} \) can be computed easily. Indeed, for all \( j \) and \( k \), the variety \( \mathcal{F}_{j, M_k} \) is either empty or a single point, so \( \chi_c(\mathcal{F}_{j, M_k}) \) is either 0 or 1. Using Theorem [13.1] we get
\[
\delta_{V_4} = \delta_{M_1} \cdot \delta_{M_4} - \delta_{M_3},
\]
\[
\delta_{V_5} = \delta_{M_2} \cdot \delta_{M_5} - \delta_{M_3},
\]
\[
\delta_{V_6} = \delta_{M_3} \cdot \delta_{M_6} - \delta_{M_4} \cdot \delta_{M_5}.
\]
Some further exchange relations are
\[
\begin{align*}
\delta V_4 \delta W_2 &= \delta V_4 \cdot \delta V_5 + \delta V_4 \delta V_6, \\
\delta V_2 \delta W_4 &= \delta W_3 + \delta V_4, \\
\delta V_1 \delta W_4 &= \delta W_3 + \delta V_5.
\end{align*}
\]

The cluster variables in \( R(\mathcal{C}_w, V_1) \) are
\[
\{ \delta M_k, \delta V_s, \delta W_t \mid 1 \leq k \leq 6, 4 \leq s \leq 6 \text{ and } 1 \leq t \leq 3 \}.
\]
(Here we consider the three coefficients \( \delta V_k \) with \( 4 \leq k \leq 6 \) also as cluster variables.) Using the above formulas we get
\[
\begin{align*}
\delta W_3 &= \delta M_6 \delta M_5 - \delta M_6 \delta M_4 - \delta M_5 \delta M_3, \\
\delta W_2 &= \delta M_6 \delta M_5 - \delta M_5 \delta M_4, \\
\delta W_1 &= \delta M_5 \delta M_4 - \delta M_4 \delta M_3.
\end{align*}
\]
So we wrote all cluster variables as linear combinations of dual PBW-basis vectors.

15.5. Generalities on bases of algebras. A \( \Lambda \)-module \( M = \bigoplus_{k=1}^{r} M_k \) in \( \text{add}(M_i) \) has gaps if for each \( 1 \leq j \leq n \) there is some \( 1 \leq k \leq r \) with \( i_k = j \) and \( a_k = 0 \). In other words, \( M \) has gaps if and only if \( M \) has no direct summand of the form
\[
M_i(\mathcal{I}_{i,j}) := M_{k_{\max}} \oplus \cdots \oplus M_{k_{\min}'} \oplus M_{k_{\min}}
\]
where \( i_j = j \).

Lemma 15.8. Let \( M = M' \oplus M'' \) be in \( \text{add}(M_i) \) such that
\[
M'' \cong M_i(\mathcal{I}_{i,j})
\]
for some \( 1 \leq j \leq n \). Then we have \( s_M = s_{M'} \cdot s_{M''} \).

Proof. We have \( s_{M''} = \delta_{R, j} \), and \( I_{i,j} \) is \( \mathcal{C}_w \)-projective-injective. The claim follows now easily from [GLS1, Theorem 1.1] in combination with the explanations in [GLS1, Section 2.6]. \( \square \)

Let \( B := \{ b_i \mid i \geq 1 \} \) be a \( K \)-basis of a commutative \( K \)-algebra \( A \). For some fixed \( n \geq 1 \) let \( C := \{ b_1, \ldots, b_n \} \). A basis vector \( b \in B \) is called \( C \)-free if \( b \notin b_iB \) for some \( b_i \in C \). Assume that the following hold:

(i) For all \( b_i \in C \) we have \( b_iB \subseteq B \);

(ii) If \( b_1^{z_1} \cdots b_n^{z_n} b = b_1^{z_1'} \cdots b_n^{z_n'} b' \) for some \( z_i, z_i' \geq 0 \) and some \( C \)-free elements \( b_i, b' \in B \), then \( b = b' \) and \( z_i = z_i' \) for all \( i \).

It follows that \( B = \{ b_1^{z_1} \cdots b_n^{z_n} b \mid b \in B \text{ is } C \text{-free}, z_i \geq 0 \} \). Define
\[
A := A/(b_1 - 1, \ldots, b_n - 1).
\]
For \( a \in A \), let \( a \) be the residue class of \( a \) in \( A \). Furthermore, let \( A_{b_1, \ldots, b_n} \) be the localization of \( A \) at \( b_1, \ldots, b_n \). The following lemma is easy to show:

Lemma 15.9. With the notation above, the following hold:

1. The set \( B := \{ b \mid b \text{ is } C \text{-free} \} \) is a \( K \)-basis of \( A \);

2. The set \( B_{b_1, \ldots, b_n} := \{ b_1^{z_1} \cdots b_n^{z_n} b \mid b \in B \text{ is } C \text{-free}, z_i \in \mathbb{Z} \} \) is a \( K \)-basis of \( A_{b_1, \ldots, b_n} \).
15.6. **Inverting and specializing coefficients.** One can rewrite the basis $S_w^*$ appearing in Theorem 5.2 as

$$S_w^* = \{(\delta_{I_{1,1}})^{z_1} \cdots (\delta_{I_{n,n}})^{z_n}s_M \mid M \in \text{add}(M_i), M \text{ has gaps}, z_i \geq 0 \}.$$  

The next two theorems deal with the situation of invertible coefficients and specialized coefficients.

**Theorem 15.10** (Invertible coefficients). The set

$$\tilde{S}_w^* := \{(\delta_{I_{1,1}})^{z_1} \cdots (\delta_{I_{n,n}})^{z_n}s_M \mid M \in \text{add}(M_i), M \text{ has gaps}, z_i \in \mathbb{Z} \}$$

is a $\mathbb{C}$-basis of $\tilde{\mathcal{R}}(C_w, V_i)$, and $\tilde{S}_w^*$ contains all cluster monomials of the cluster algebra $\tilde{\mathcal{R}}(C_w, V_i)$.

Next, we specialize all $n$ coefficients $\delta_{I_{i,j}}$ of the cluster algebra $\mathcal{R}(C_w, V_i)$ to 1. We obtain a new cluster algebra $\mathcal{R}(C_w, V_i)$ which does not have any coefficients. The residue class of $\delta_X \in \mathcal{R}(C_w, V_i)$ is denoted by $\hat{\delta}_X$. The residue class of a dual semicanonical basis vector $s_M$ is denoted by $\hat{s}_M$.

**Theorem 15.11** (No coefficients). The set

$$\hat{S}_w^* := \{\hat{s}_M \mid M \in \text{add}(M_i), M \text{ has gaps} \}$$

is a $\mathbb{C}$-basis of $\hat{\mathcal{R}}(C_w, V_i)$, and $\hat{S}_w^*$ contains all cluster monomials of the cluster algebra $\hat{\mathcal{R}}(C_w, V_i)$.

**Proof of Theorem 15.10 and Theorem 15.11.** Let $B := \{b_i \mid i \geq 1\} := S_w^*$ be the dual semicanonical basis of $\mathcal{R}(C_w, V_i)$. We can label the $b_i$ such that

$$\{b_1, \ldots, b_n\} = \{\delta_{I_{1,1}}, \ldots, \delta_{I_{n,n}}\}.$$  

Using Lemma 15.8 it is easy to check that the elements $b_i$ satisfy the properties (i) and (ii) mentioned in Section 15.5. Then apply Lemma 15.9.  

16. **Acyclic cluster algebras**

In this section we will study the case of acyclic cluster algebras, which is of special interest. As before, let $Q$ be an acyclic quiver with vertices $1, \ldots, n$. Without loss of generality we assume that $i < j$ whenever there is an arrow $a : i \to j$ in $Q$. We define two Weyl group elements $c := s_n \cdots s_2 s_1$ and $w := c^2$. For simplicity we assume that $Q$ is not a linearly oriented quiver of type $A_n$. This implies that $i := (n, \ldots, 2,1,n,\ldots, 2,1)$ is a reduced expression of $w$. Define $V_1 = V_1 \oplus \cdots \oplus V_{2n}$ and $M_i = M_1 \oplus \cdots \oplus M_{2n}$ as before.

It follows that for $1 \leq j \leq n$ we have $M_j = I_j$ and $M_{n+j} = \tau_Q(I_j)$. Here $I_j$ denotes the indecomposable injective $KQ$-module with socle $S_j$, and $\tau_Q$ is the Auslander-Reiten translation in mod($KQ$).

Observe that $\mathcal{R}(C_w, V_i)$ is an acyclic cluster algebra associated to $Q$ having $n$ non-invertible coefficients, whereas $\hat{\mathcal{R}}(C_w, V_i)$ is the acyclic cluster algebra associated to $Q$ having no coefficients.

**Theorem 16.1.** With $w$ and $i$ as above, the following hold:

(i) $\mathcal{R}(C_w, V_i) = \mathbb{C}[\delta_{M_1}, \ldots, \delta_{M_{2n}}] = \text{Span}_\mathbb{C}\langle \delta_X \mid X \in C_w \rangle$;

(ii) $\{\delta_{M} \mid M \in \text{add}(M_i)\}$ and $\{s_{M} \mid M \in \text{add}(M_i)\}$ are both a $\mathbb{C}$-basis of $\mathcal{R}(C_w, V_i)$;

(iii) $\{\hat{s}_{M} \mid M \in \text{add}(M_i), M \text{ has gaps} \}$ is a $\mathbb{C}$-basis of $\hat{\mathcal{R}}(C_w, V_i)$;

(iv) $\{\hat{\delta}_{M} \mid M \in \text{add}(M_i), M \text{ has gaps} \}$ is a $\mathbb{C}$-basis of $\hat{\mathcal{R}}(C_w, V_i)$;
Our version of Theorem 16.2 looks then as follows:

A is a seed of the cluster algebra

\[ C \]

form a

\[ \text{y} \]

denote by

\[ \text{Berenstein, Fomin, Zelevinsky} \]

Theorem 16.2

\[ n \]

\[ \text{initial cluster} \]

\[ \text{µ} \]

\[ \text{sequence of mutations} \]

where

\[ \delta \]

\[ s \]

\[ \text{which has gaps, the vector} \]

\[ V \]

(labeled by

\[ \text{of arbitrary Weyl group elements. Part (v) is clear from our description of the initial seed (labeled by} \]

\[ V_i \]

\[ \text{for the cluster algebra} \]

\[ R(C_w, V_i) \]

. It remains to prove (iv): We have

\[ R(C_w, V_i) = \bigoplus_{d \in \mathbb{N}^n} R_d \]

where \[ R_d \] is the \( \mathbb{C} \)-vector space with basis \( \{ s_M \mid M \in \text{add}(M_i) \cap \text{rep}(Q, d) \} \). We know that

\[ \{ \delta_M \mid M \in \text{add}(M_i) \cap \text{rep}(Q, d) \} \]

denote a basis of \( R_d \) as well. After specializing the coefficients \( \delta_{i,j}, 1 \leq j \leq n \) to 1, we get

\[ R(C_w, V_i) = \bigoplus_{d \in \mathbb{N}^n} R_d \]

where \( R_d \) is the \( \mathbb{C} \)-vector space with basis

\[ \{ s_M \mid M \in \text{add}(M_i) \cap \text{rep}(Q, d), M \text{ has gaps} \} \].

Now one can use the formula

\[ \delta_{i,i} = \delta_{M_n+i} \cdot \delta_{M_i} - \prod_{j \rightarrow i} \delta_{M_{n+j}} \cdot \prod_{i \rightarrow k} \delta_{M_k} \]

(where the products are taken over all arrows of \( Q \) which start and end in \( i \), respectively) and an induction on the number of vertices of \( Q \) to show that for every \( M \in \text{add}(M_i) \) which has gaps, the vector \( s_M \) is a linear combination of elements of the form \( \delta_{M'} \) where \( M' \) in \( \text{add}(M_i) \) has gaps and \( |\dim(M')| \leq |\dim(M)| \). For dimension reasons we get that the vectors \( \delta_{M'} \) with \( M' \) having gaps form a linearly independent set. This implies (iv). □

It is interesting to compare Theorem 16.1 (iv) to Berenstein, Fomin and Zelevinsky’s construction of a basis for the acyclic cluster algebra \( A_Q \). Let \( y := (y_1, \ldots, y_n) \) be the initial cluster whose exchange matrix \( B_Q \) is encoded by \( Q \), as in Section 2.6. Let \( y_1^\dagger, \ldots, y_n^\dagger \) be the \( n \) cluster variables obtained from \( y \) by one mutation in each of the \( n \) possible directions. Thus the \( n \) sets \( \{y_1, \ldots, y_n\} \setminus \{y_k\} \cup \{y_k^\dagger\} \) form the neighboring clusters of our initial cluster \( y \). Using a simple Gröbner basis argument, the following is shown in [BFZ]:

**Theorem 16.2** (Berenstein, Fomin, Zelevinsky). The monomials

\[ \{ y_1^{p_1}(y_1^\dagger)^{q_1} \cdots y_n^{p_n}(y_n^\dagger)^{q_n} \mid p_i, q_i \geq 0, p_iq_i = 0 \} \]

form a \( \mathbb{C} \)-basis of the acyclic cluster algebra \( A_Q \).

Starting with the initial seed \( (y, B_Q) \), which corresponds to \( \Gamma_1 \equiv \Gamma_{V_i} \), we perform the sequence of mutations \( \mu_n \cdots \mu_2 \mu_1 \). In each step we obtain a new cluster variable which we denote by \( y_k^\dagger \). Note that \( y_1^\dagger = y_1^\dagger \), but already \( y_2^\dagger \) and \( y_2^\dagger \) may be different. Observe that \( \mu_n \cdots \mu_2 \mu_1(B_Q) = B_Q \). We get that

\[ ((y_1^\dagger, \ldots, y_n^\dagger), B_Q) \]

is a seed of the cluster algebra \( A_Q \) where

\[ \{y_1, \ldots, y_n\} \cap \{y_1^\dagger, \ldots, y_n^\dagger\} = \emptyset. \]

Our version of Theorem 16.2 looks then as follows:
Theorem 16.3. The monomials
\[ \left\{ y_1^{p_1}(y_1^\dagger)^{q_1} \cdots y_n^{p_n}(y_n^\dagger)^{q_n} \mid p_i, q_i \geq 0, p_iq_i = 0 \right\} \]
form a \( \mathbb{C} \)-basis of the acyclic cluster algebra \( A_Q \).

Note that the initial cluster \( (y_1, \ldots, y_n) \) comes from \( V_i \) and the cluster \( (y_1^\dagger, \ldots, y_n^\dagger) \) comes from \( T_i \).

17. Coordinate rings of unipotent radicals

In this section, we assume that \( Q \) is of finite Dynkin type \( A, D, E \). We first recall some
standard notation (we refer the reader to [GLS6] for more details). The group \( G \) is now a
simple complex algebraic group of the same type as \( Q \). Let \( J \) be a subset of the set \( I \) of
vertices of \( Q \), and let \( K \) be the complementary subset. To \( K \) one can attach a standard
parabolic subgroup \( B_K \) containing the Borel subgroup \( B = HN \). We denote by \( N_K \) the
unipotent radical of \( B_K \). This is a subgroup of \( N \). Let \( W_K \) be the subgroup of the Weyl
group \( W \) generated by the reflections \( s_k \) with \( k \in K \). This is a finite Coxeter group and
we denote its longest element by \( w_{K0} \). The longest element of \( W \) is denoted by \( w_0 \).

In finite type, the preprojective algebra \( \Lambda \) is finite-dimensional and selfinjective. In
agreement with [GLS6], we shall denote by \( P_i \) the indecomposable projective \( \Lambda \)-module
with top \( S_i \) and by \( Q_i \) the indecomposable injective module with socle \( S_i \). We write
\[ Q_J = \bigoplus_{j \in J} Q_j \quad \text{and} \quad P_J = \bigoplus_{j \in J} P_j. \]

In [GLS6] we have shown that \( \mathbb{C}[N_K] \) is naturally isomorphic to the subalgebra
\[ R_K := \text{Span}_\mathbb{C}\langle \phi_X \mid X \in \text{Sub}(Q_J) \rangle \]
of \( \mathbb{C}[N] \). As before, \( \text{Sub}(Q_J) \) is the full subcategory of \( \text{mod}(\Lambda) \) whose objects are submodules of direct sums of finitely many copies of \( Q_J \). This allowed us to introduce a cluster algebra \( A_J \subseteq R_K \), whose cluster monomials are of the form \( \phi_X \) with \( X \) a rigid module in \( \text{Sub}(Q_J) \). We conjectured that in fact \( A_J = R_K \), see [GLS6, Conjecture 9.6].

We are going to prove that this conjecture follows from the results of this paper. Let \( w := w_0w_{K0} \), and let \( i \) be a reduced expression for \( w \).

**Lemma 17.1.** We have \( N_K = N'(w_0^K) = N(w_0w_{K0}) \).

**Proof.** We know that \( N'(w_0^K) \) is the subgroup of \( N \) generated by the one-parameter subgroups \( N(\alpha) \) with \( \alpha > 0 \) and \( w_0^K(\alpha) > 0 \). These are exactly the one-parameter subgroups of \( N \) which do not belong to the Levi subgroup of \( B_K \), hence the first equality follows. Now, since \( N = w_0Nw_0 \), we have
\[ N'(w_0^K) = N \cap (w_0^K N w_0^K) = N \cap (w_0^K w_0 N w_0^K) = N(w_0w_{K0}^K). \]

As before, let \( \text{Fac}(P_J) \) be the subcategory of \( \text{mod}(\Lambda) \) whose objects are factor modules of direct sums of finitely many copies of \( P_J \).

**Lemma 17.2.** We have \( \mathcal{C}_{w_0w_{K0}^K} = \text{Fac}(P_J) \).
Proof. By Proposition [9.1] we know that the indecomposable $C_w$-projective-injective object $I_{i,i}$ with socle $S_i$ satisfies

$$\varphi_{i,i} = D_{w_i, w_0^K w_0(w_i)}, \quad (i \in I).$$

By [GLS6 §6.2], it follows that $I_{i,i} = \mathcal{E}_{w_0^K} Q_i$, where $\mathcal{E}_{w_0^K}$ is the functor defined in [GLS6 §5.2]. It readily follows that $I_{i,i}$ is the indecomposable projective-injective object of $\text{Fac}(P_j)$ with simple socle $S_i$. Hence $C_{w_0 w_0^K}$ and $\text{Fac}(P_j)$ have the same projective-injective generator. □

Let $S$ denote the self-duality of mod($\Lambda$) induced by the involution $a \mapsto a^*$ mapping an arrow $a$ of $\overline{Q}$ to its opposite arrow $a^*$, see [GLS2 §1.7]. This restricts to an anti-equivalence of categories $\text{Fac}(P_j) \to \text{Sub}(Q_j)$, that we shall again denote by $S$.

**Lemma 17.3.** For every $X \in \text{nil}(\Lambda)$ and every $n \in N$ we have

$$\varphi_X(n^{-1}) = (-1)^{\dim X} \varphi_{S(X)}(n).$$

**Proof.** We know that $N$ is generated by the one-parameter subgroups $x_i(t)$ attached to the simple positive roots. By Proposition [6.1] we have

$$\varphi_X(x_{i_1}(t_1) \cdots x_{i_k}(t_k)) = \sum_{a = (a_1, \ldots, a_k) \in \mathbb{N}^k} \chi_c(F_{a,X}) \frac{a_1^{\alpha_{i_1}} \cdots a_k^{\alpha_{i_k}}}{a_1! \cdots a_k!}.$$

Now, if $n = x_{i_1}(t_1) \cdots x_{i_k}(t_k)$, we have $n^{-1} = x_{i_k}(-t_k) \cdots x_{i_1}(-t_1)$ and the result follows from the fact that $F_{a,X} \cong F_{a_{op}, S(X)}$, where $i_{op}$ and $a_{op}$ denote the sequences obtained by reading $i$ and $a$ from right to left. □

We can now prove the following:

**Theorem 17.4.** Conjecture 9.6 of [GLS6] holds.

**Proof.** As before, let $w := w_0 w_0^K$, and let $i$ be a reduced expression of $w$. The cluster algebra $\mathcal{R}(C_w) = \mathcal{R}(\text{Fac}(P_j))$ is isomorphic to $\mathcal{A}_j$ via the map $\varphi_X \mapsto \varphi_{S(X)}$. This comes from the fact that $S_j : \text{Fac}(P_j) \to \text{Sub}(Q_j)$ is an anti-equivalence which maps the $C_w$-maximal rigid module $V_i$ used to define the initial seed of $\mathcal{R}(C_w)$ to the maximal rigid module $U_j$ of [GLS6 §9.2] used to define the initial seed of $\mathcal{A}_j$. (Here we assume that $j$ is the reduced expression of $w_0^K w_0$ obtained by reading the reduced expression $i$ of $w_0 w_0^K$ from right to left.) In particular the cluster variables $\varphi_{M_k}$ which, by Theorem [15.1] generate $\mathcal{R}(\text{Fac}(P_j)) \cong \mathbb{C}[N(w_0 w_0^K)]$ are mapped to cluster variables $\varphi_{S(M_k)}$ of $\mathcal{A}_j$. They also form a system of generators of the polynomial algebra $\mathbb{C}[N(w_0 w_0^K)] = \mathbb{C}[N_K]$ by Lemma [17.3] because the map $n \mapsto n^{-1}$ is a birigid automorphism of $N_K$. Hence $\mathcal{A}_j = \mathbb{C}[N_K]$. □

**Remark 17.5.** The previous discussion shows that we obtain two different cluster algebra structures on $\mathbb{C}[N_K]$, coming from the two different subcategories $\text{Fac}(P_j)$ and $\text{Sub}(Q_j)$. When using $\text{Fac}(P_j) = C_{w_0 w_0^K}$, we regard $\mathbb{C}[N_K]$ as the subring of $N'(w_0 w_0^K)$-invariant functions of $\mathbb{C}[N]$ for the action of $N'(w_0 w_0^K)$ on $N$ by right translations, see Section [8.1]. This allows us to relate the first cluster structure to the cluster structure of the unipotent cell $\mathbb{C}[N w_0 w_0^K]$, see Proposition [8.5]. When using $\text{Sub}(Q_j)$, we regard $\mathbb{C}[N_K]$ as the subring of $N'(w_0 w_0^K)$-invariant functions of $\mathbb{C}[N]$ for the action of $N'(w_0 w_0^K) = N(w_0^K)$ on $N$ by left translations. These functions can then be “lifted” to $B_K^-$-invariant functions on $G$ for the action of $B_K^-$ on $G$ by left translations. This allows us to “lift” the second cluster structure to a cluster structure on $\mathbb{C}[B_K^G]$, see [GLS6 §10].
18. Remarks and open problems

18.1. Calculation of $M_i(R)$. Let $i$ be a reduced expression of a Weyl group element $w$, and let $R$ be a $V_i$-reachable $\Lambda$-module, see Section 3.1. Based on Theorem 3.1 we can combine Corollary [10.7] and Proposition [12.3] to determine algorithmically $M_i(R)$. (For the definition of $M_i(R)$ see Section 10) Recall that the $V_i$-reachable modules $R$ are in 1-1 correspondence with the cluster monomials $\delta_R$ in $R(C_w)$.

18.2. Calculation of Euler characteristics. Let $i$ be a reduced expression of a Weyl group element $w$, and let $R$ be a $V_i$-reachable $\Lambda$-module, and let $j = (j_1, \ldots, j_p)$. By Proposition 6.1 the Euler characteristic $\chi_c(F_{j,R})$ is equal to the coefficient of $t_1 \cdots t_p$ in $\varphi_R(x_{j_1}(t_1) \cdots x_{j_p}(t_p))$. Using mutations, we can express algorithmically $\varphi_R$ as a Laurent polynomial in the functions $\varphi_{V_1}, \ldots, \varphi_{V_s}$. Now we can use the calculations from Section 9.6 to compute all the Euler characteristics $\chi_c(F_{j,R})$.

18.3. Open orbit conjecture. It is known that the (specialized) dual canonical basis $B^*$ and the dual semicanonical basis $S^*$ of $\mathcal{M}^* \equiv U(n)^*_{q,t}$ do not coincide, see [GLS1, Section 1.5]. But one might at least hope that both bases have some interesting elements in common:

Conjecture 18.1 (Open Orbit Conjecture). Let $Z$ be an irreducible component of $\Lambda_d$, and let $b_Z$ and $\rho_Z$ be the associated dual canonical and dual semicanonical basis vectors of $\mathcal{M}^*$. If $Z$ contains an open $\text{GL}_d$-orbit, then $b_Z = \rho_Z$.

We know that each cluster monomial of the cluster algebra $A(C_w)$ is of the form $\rho_Z$, where $Z$ contains an open $\text{GL}_d$-orbit. So if the conjecture is true, then all cluster monomials belong to the dual canonical basis.

18.4. Example. Finally, we would like to ask the following question. Is it possible to realize every element of the dual canonical basis of $\mathcal{M}^*$ as a $\delta$-function? We know several examples of elements $b$ of $B^*$ which do not belong to $S^*$. In all these examples, $b$ is however equal to $\delta_X$ for a non-generic $\Lambda$-module $X$. (We say that $X \in \text{nil}(\Lambda)$ is generic if $\delta_X \in S^*$.)

Let us look at an example. Let $Q$ be the quiver $1 \leftarrow 2$ and let $\Lambda$ be the associated preprojective algebra. For $\lambda \in \mathbb{C}^*$ we define representations $M(\lambda, 1)$ and $M(\lambda, 2)$ of $Q$ as follows:

\[ M(\lambda, 1) := \mathbb{C} \begin{pmatrix} 1 \\
\lambda \end{pmatrix} \quad \text{and} \quad M(\lambda, 2) := \mathbb{C}^2 \begin{pmatrix} 1 & 0 \\
\lambda & 1 \end{pmatrix} \]

Let $\iota: \text{rep}(Q, (2, 2)) \rightarrow \Lambda_{(2,2)}$ be the obvious canonical embedding. Clearly, the image of $\iota$ is an irreducible component of $\Lambda_{(2,2)}$, which we denote by $Z_Q$. It is not difficult to check that the set

\[ \{ M(\lambda, 1) \oplus M(\mu, 1) \mid \lambda, \mu \in \mathbb{C}^* \} \]

is a dense subset of $Z_Q$. It follows that

\[ \delta_{M(\lambda, 1) \oplus M(\mu, 1)} = \rho_{Z_Q} \]

is an element of the dual semicanonical basis $S^*$. It is easy to check that

\[ \delta_{M(\lambda, 2)} \neq \delta_{M(\lambda, 1) \oplus M(\mu, 1)}. \]
Indeed, the variety $\mathcal{F}_{j,X}$ of composition series of type $j = (1, 2, 1, 2)$ has Euler characteristic 2 for $X = M(\lambda, 1) \oplus M(\mu, 1)$ and Euler characteristic 1 for $X = M(\lambda, 2)$. Furthermore, one can show that 

$$\delta_{M(\lambda, 2)} = b_{ZQ}$$

belongs to the dual canonical basis $B^*$ of $M^*$.

Note that the functions $\delta_{M(\lambda, 1) \oplus M(\mu, 1)}$ and $\delta_{M(\lambda, 2)}$ do not belong to any of the subalgebras $R(C_w)$, since $M(\lambda, 1)$ and $M(\lambda, 2)$ are regular representations of the quiver $Q$ for all $\lambda$.

Acknowledgements. We are grateful to Øyvind Solberg for answering our questions on relative homology theory. We thank Shrawan Kumar for his kind help concerning Kac-Moody groups. It is a pleasure to thank the Mathematisches Forschungsinstitut Oberwolfach (MFO) for two weeks of hospitality in July/August 2006, where this work was started. Furthermore, the first and second authors like to thank the Max-Planck Institute for Mathematics in Bonn for a research stay in September - December 2006 and October 2006, respectively. We also thank the Sonderforschungsbereich/Transregio SFB 45 for financial support. The three authors are grateful to the Mathematical Sciences Research Institute in Berkeley (MSRI) for an invitation in Spring 2008 during which substantial parts of this work were written. The first author was partially supported by PAPIIT grant IN103507-2 and CONACYT grant 81948. All three authors thank the Hausdorff Center for Mathematics in Bonn for financial support.
