Abstract

This paper studies distributed optimal formation control with hard constraints on energy levels and termination time, in which the formation error is to be minimized jointly with the energy cost. The main contributions include a globally optimal distributed formation control law and a comprehensive analysis of the resulting closed-loop system under those hard constraints. It is revealed that the energy levels, the task termination time, the steady-state error tolerance, as well as the network topology impose inherent limitations in achieving the formation control mission. Most notably, the lower bounds on the achievable termination time and the required minimum energy levels are derived, which are given in terms of the initial formation error, the steady-state error tolerance, and the largest eigenvalue of the Laplacian matrix. These lower bounds can be employed to assert whether an energy and time constrained formation task is achievable and how to accomplish such a task. Furthermore, the monotonicity of those lower bounds in relation to the control parameters is revealed. A simulation example is finally given to illustrate the obtained results.

Key words: Energy constraint; time constraint; formation control; distributed control; optimal control; multi-agent system.

1 Introduction

This paper is concerned with energy and time constraints and performance tradeoff issues one frequently encounters in distributed formation control of multi-agent systems. A fundamental problem under investigation is how energy level, mission termination time, and steady-state error tolerance may inherently impact on the achievable performance of formation control, and how such impacts may be quantified analytically. Formation control problems have been widely studied in the recent literature (see, e.g., [1–6] and the references therein). However, only a rather limited number of works have considered energy constraints [7–10], though the issue is of significant importance for agents with limited energy supplied by on-board batteries.

The energy and time constraints impose severe limitations on distributed cooperative control design and have motivated several existing works involving various cooperative tasks [11–16], wherein the energy cost is defined as an integral of the square of the input, and is to be minimized, together, with certain control error functions. Other relevant attempts have been pursued by researchers to reduce redundant communication to decrease the energy cost [17, 18]. In addition, it has been recognized that the resistance caused by velocity mismatches may also contribute to the energy expenditure, which cannot be ignored for systems with relatively high velocities [19, 20].

The LQR-based method is just one case of many efforts which seek to limit the energy consumption. It is noted that a direct application of the LQR-based method to multi-agent systems will generically require an all-to-all network topology (see, e.g., [21, 22]). That is, there is a dilemma between distributed control and LQR-based optimal control. Very recently, a network approximation approach is developed in [23] by introducing a “minimal” distribution cost in the LQR function, which guarantees
that the resulting control law is optimal in the global sense.

The present paper continues the aforementioned development in the study of energy-aware formation control of multi-agent systems. The main contributions are three-fold. Firstly, a distributed formation control law is derived which is globally optimal with respect to a cost pertinent to energy and control error of the multi-agent system under the LQR framework. To the best of the authors’ knowledge, the proposed algorithm is the first formation control algorithm that is concurrently distributed and optimal while satisfying the hard constraints on energy expenditure and convergence time. Secondly, the conditions on the feasibility of the formation control problem are derived analytically, which depends upon the initial energy level, the formation termination time, the steady-state error tolerance, the network topology, as well as the control parameters. Thirdly, monotonicity properties of the achievable formation control missions under time and energy constraints. A preliminary version of the results discussed here has appeared in [24]. With respect to [24], the current version provides a comprehensive analysis on the monotonicity properties of the PARE solution, the termination time, as well as the energy expenditure. Moreover, numerical examples are also provided to illustrate the validity of the proposed results.

The rest of this paper is organized as follows. In Section 2, preliminaries are presented and the problem is formulated. Section 3 is devoted to the development of the optimal distributed control algorithm and its analysis. Section 4 discusses the monotonicity properties of the achievable formation time and the required minimum energy with respect to the control parameters. Simulation results are presented in Section 5. Finally, Section 6 concludes the paper.

2 Preliminaries and problem statement

2.1 Notation

Let $\mathbb{R}$ denote the set of real numbers, $\mathbb{R}^+$ the set of positive real numbers, $\mathbb{R}^n$ the set of $n$-dimensional real vectors, and $\mathbb{R}^{n \times n}$ the set of $n \times n$ real matrices. Let $I_n \in \mathbb{R}^{n \times n}$ be the $n$-dimensional identity matrix, $0_n \in \mathbb{R}^n$ the vector with all zeros, and $1_n \in \mathbb{R}^n$ the vector with all ones. The subscripts of $I_n$, $0_n$, and $1_n$ might be dropped if no confusion arises from the context. The superscript $T$ denotes the transpose of a matrix or a vector. The set of the eigenvalues of $A$ is denoted by $\text{spec}(A)$. The Euclidean norm is given by $\| \cdot \|$. For two matrices $A \in \mathbb{R}^{m \times n}$ and $B \in \mathbb{R}^{p \times q}$, their Kronecker product is denoted by

$$A \otimes B = \begin{bmatrix} a_{11}B & \cdots & a_{1n}B \\ \vdots & \ddots & \vdots \\ a_{m1}B & \cdots & a_{mn}B \end{bmatrix}.$$ 

The abbreviation “iff” means “if and only if”.

2.2 Graph theory

The information exchange among the agents is described by a graph $G = (\mathcal{V}, \mathcal{E})$, where $\mathcal{V} = \{\nu_1, \ldots, \nu_N\}$ is the set of nodes and $\mathcal{E} \subseteq \mathcal{V} \times \mathcal{V}$ is the set of edges. In this paper, the graph $G$ is assumed to be undirected. The adjacency matrix $A = [a_{ij}] \in \mathbb{R}^{N \times N}$ of $G$ is defined as: $a_{ij} = 1$ if $(i, j) \in \mathcal{E}$, and $a_{ij} = 0$ otherwise. The degree matrix is then given by $D = \text{diag}([d_1, \ldots, d_N])$, where $d_i = \sum_{j=1}^N a_{ij}$. A path from node $v_i$ to node $v_j$ is a sequence of nodes $v_i, \ldots, v_j$, such that each two consecutive nodes in the sequence is connected by an edge. An undirected graph is connected if for any two vertices in $\mathcal{V}$, there always exists a path connecting them. Throughout the paper, the following assumption is made.

Assumption 1 Graph $G$ is undirected and connected.

The Laplacian matrix of the undirected graph $G$ is given by $L = D - A \in \mathbb{R}^{N \times N}$, which is known to be symmetric and positive semi-definite. It has a zero eigenvalue whose normalized eigenvector is $\frac{1}{\sqrt{N}}1_N$, where $1_N \in \mathbb{R}^N$ is the vector with all one. The $N$ real eigenvalues of $L$ can be ordered as $0 = \lambda_1 \leq \lambda_2 \leq \cdots \leq \lambda_N$. Let $W = [w_1, \ldots, w_N]^T$ be the matrix comprising orthonormal eigenvectors of $L$. The Laplacian matrix $L$ can be diagonalized as follows:

$$L = W^T J W,$$

where $J = \text{diag}([\lambda_1, \ldots, \lambda_N])$.

2.3 Problem statement

Consider a multi-agent system consisting of $N$ agents moving in the $n$-dimensional space. Each agent is governed by the following equations:

$$\dot{p}_i(t) = v_i(t), \quad \dot{v}_i(t) = u_i(t),$$

$$\dot{E}_i(t) = -u_i^T(t)u_i(t) - \frac{\beta}{2} \sum_{i=1}^N a_{ij} ||v_i(t) - v_j(t)||^2,$$ 

$$p_i(0) = p_i^0, \quad v_i(0) = v_i^0, \quad E_i(0) = E_i^0, \quad i = 1, \ldots, N,$$

where $p_i(t) \in \mathbb{R}^n$, $v_i(t) \in \mathbb{R}^n$, $u_i(t) \in \mathbb{R}^n$, and $E_i(t) \in \mathbb{R}$ denote, respectively, the position, velocity, input, and
energy level of agent $i$, and $p_i^0 \in \mathbb{R}^n$, $v_i^0 \in \mathbb{R}^n$, and $E_i^0 \in \mathbb{R}$ are their initial values. Equation (2) describes the double-integrator dynamics of the agents, while Eq. (3) delineates how the energy level of the agents changes. The first term of (3) represents the energy expenditure caused by the control input, while the second term represents the energy expenditure due to the resistance of velocity mismatch, where $\beta$ is a positive constant. Let

$$J_E(t) = \int_0^t -\dot{E}_i(\tau) d\tau$$

be the energy consumed by agent $i$ till time $t$. The energy cost of the multi-agent system is given by

$$J_E(t) = \sum_{i=1}^N \int_0^t -\dot{E}_i(\tau) d\tau$$

$$= \int_0^t \{u^T(\tau) u(\tau) + \beta v^T(\tau) (\mathcal{L} \otimes I_n) v(\tau)\} d\tau, \quad (4)$$

where $u(\tau) = [u_1^T(\tau), \ldots, u_N^T(\tau)]^T \in \mathbb{R}^{Nn}$ and $v(\tau) = [v_1^T(\tau), \ldots, v_N^T(\tau)]^T \in \mathbb{R}^{Nn}$. For notational convenience, $J_E(\infty)$ will be simplified as $J_E$ in the rest of the paper.

Define $x_i(t) = [p_i^T(t) \quad v_i^T(t)]^T \in \mathbb{R}^{2n}$. Equation (2) can be written compactly as

$$\dot{x}_i(t) = Ax_i(t) + Bu_i(t), \quad (5)$$

where $A = \begin{bmatrix} 0 & 1 \end{bmatrix} \otimes I_n$ and $B = \begin{bmatrix} 0 \\ 1 \end{bmatrix} \otimes I_n$. Let

$$x^d = [(p_1^d)^T \quad (v_1^d)^T]^T \in \mathbb{R}^{2Nn}$$

represents the desired state with $p^d = [(p_1^d)^T, \ldots, (p_N^d)^T]^T \in \mathbb{R}^{Nn}$ and $v^d = [(v_1^d)^T, \ldots, (v_N^d)^T]^T \in \mathbb{R}^{Nn}$ denoting, respectively, the desired position and velocity. To guarantee the tracking result, it is necessary that all agents have the same desired velocity. Particularly, for notational convenience, it is assumed that $v^d = 0$. Accordingly, the energy cost function (4) can be rewritten in terms of $u(t)$ and $x(t)$ as

$$J_E = \int_0^\infty \{u^T(t) u(t) + \beta [x(t) - x^d]^T (\mathcal{L} \otimes Q) x(t) - x^d]\} \quad \times \left[ [x(t) - x^d]^T (\mathcal{L} \otimes Q) [x(t) - x^d] \right] dt, \quad (6)$$

where $Q = \text{diag}(\begin{bmatrix} 0 & 1 \end{bmatrix}) \otimes I_n$, $x(t) = [x_1^T(t), \ldots, x_N^T(t)] \in \mathbb{R}^{2Nn}$. Let $d_{ij} = [(p_j^i)^T \quad (v_j^i)^T]^T$ denote the prespecified relative state between agent $i$ and $j$, i.e., $p_j^i = p_i^d - p_j^d$ and $v_j^i = v_i^d - v_j^d = 0$. Let $T$ be the termination time of the formation task, and $\varepsilon \in \mathbb{R}^+$ be the parameter of the steady-state error tolerance. The following problem is investigated in the paper.

**Problem 1** Design a distributed control input $u_i(t)$ for the system (5), based on local information, such that for some $t_f \in \mathbb{R}^+$,

$$\limsup_{t \to t_f} \|x_i(t) - x_j(t) - d_{ij}\| \leq \varepsilon$$

$$\text{s.t.} \quad t_f \leq T, \quad J_E(T) < E_i^0. \quad (7)$$

It is worth pointing out that $t_f \leq T$ and $J_E(T) < E_i^0$ are two “hard” constraints on the formation task. If $t_f > T$, the formation task fails to be achieved since it is not accomplished in a timely manner. On the other hand, $J_E(T) \geq E_i^0$ means that the energy is exhausted before the mission is completed.

### 3 Distributed optimal energy-aware formation control

This section is devoted to the development of an energy-aware distributed formation control algorithm by employing solely local information. To this aim, define the performance measure

$$J = J_E + J^f_x + J_{x}^{NA},$$

where the energy cost $J_E$ is defined in (6), and

$$J^f_x = \alpha \int_0^\infty [x(t) - x^d]^T (\mathcal{L} \otimes I_{2n}) [x(t) - x^d] dt$$

$$= \frac{\alpha}{2} \int_0^\infty \sum_{i=1}^N a_{ij} \|x_i(t) - x_j(t) - d_{ij}\|^2 dt,$$

$$J_{x}^{NA} = \alpha \int_0^\infty [x(t) - x^d]^T [M \otimes S] [x(t) - x^d] dt.$$ Here, $\alpha > 0$ is a tradeoff parameter, $M = \alpha (\mathcal{L}^2 - \sigma \mathcal{L})$ with $0 < \sigma < \lambda_2$, and $S \geq 0$ is a positive semi-definite matrix to be designed. The formation cost term $J^f_x$ represents the accumulated formation error, and ensures that the formation is reached asymptotically. It has been recognized that for a multi-agent system, the LQR-based optimal control law only exists under an all-to-all network topology [21]. To circumvent the difficulty, the distribution cost term $J_{x}^{NA}$ is introduced to warrant that the optimal distributed control law exists for a generic connected network topology [23]. The main results of this section are given as follows.

**Theorem 1** Let

$$P = \frac{1}{\sqrt{\sigma \alpha}} \left[ \sqrt{\sigma \alpha + \beta \sigma + 2 \sqrt{\sigma \alpha}} \right] \otimes I_n,$$

where $0 < \sigma < \lambda_2$ with $\lambda_2$ being the second smallest
eigenvalue of the Laplacian matrix $\mathcal{L}$. If $M = \alpha (\mathcal{L}^2 - \sigma \mathcal{L})$, $S = P \mathcal{B} B^T P$, and Assumption 1 holds, then

(1) the optimal distributed control input of (5) that minimizes $J$ is given by

$$u^*_i(t) = -\alpha \sum_{j=1}^{N} a_{ij} B^T P [x^*_i(t) - x^*_j(t) - d_{ij}],$$

where $x^*_i(t)$ is the state under the optimal input $u^*_i(t)$ at time $t$;

(2) for given initial energy $E(0) = [E_1(0), \ldots, E_N(0)]^T \in \mathbb{R}^N$, termination time $T > 0$, and steady-state error tolerance $\epsilon > 0$, if the following inequalities hold

$$\begin{cases} T \geq \lambda_{\min}(P) \ln \frac{V(x(0))}{\lambda_{\min}(P)(N-1)^2}, \\
e_{i}(0) \geq \frac{V_{\mathcal{L}}(0)}{2} \left[ \lambda_N \left( \frac{\alpha + 1}{\sigma} \right) \left( \alpha + \beta + 2 \sqrt{\frac{\alpha}{\sigma}} \right) \\
+ \beta \left( 1 + \frac{\beta}{\alpha} + \frac{2}{\sqrt{\alpha \sigma}} \right) \left( 1 - e^{-\lambda_N \sqrt{\beta \alpha}} \right)^T \right], \end{cases}$$

$$i \in \{1, \ldots, N\},$$

where

$$\lambda_{\min}(P) = \frac{1}{2 \sqrt{\sigma \alpha}} \left( \left( 1 + \sqrt{\sigma \alpha} \right) \sqrt{\frac{\beta}{\alpha} + \frac{2}{\sqrt{\sigma \alpha}}}
- \sqrt{\left( 1 + \sqrt{\sigma \alpha} \right) \left( 1 + \frac{\beta}{\alpha} + \frac{2}{\sqrt{\sigma \alpha}} \right) + 4} \right),$$

$$V(x(0)) = [x(0) - x^0]^T \left( I_N - \frac{1}{N} 1 1^T \right) \otimes P \times [x(0) - x^0]^T,$$

$$V_{\mathcal{L}}(0) = [x(0) - x^0]^T (\mathcal{L} \otimes I_{2n}) [x(0) - x^0],$$

then Problem 1 is solved under the distributed optimal control algorithm (8).

**Proof**

1) Define

$$J(t_f, x(t_f))$$

$$= \int_{0}^{t_f} \{ u^T(t)u(t) + \beta [x(t) - x^0]^T (\mathcal{L} \otimes Q) [x(t) - x^0] \} dt$$

$$+ \alpha \left( \int_{0}^{t_f} [x(t) - x^0]^T (\mathcal{L} \otimes I_{2n}) [x(t) - x^0] dt \right.$$

$$+ \int_{0}^{t_f} [x(t) - x^0]^T [M \otimes S(t)] [x(t) - x^0] dt$$

$$+ [x(t_f) - x^0]^T (\mathcal{L} \otimes I_{2n}) [x(t_f) - x^0] \},$$

where $S(t) \in \mathbb{R}^{2n \times 2n}$ is a time-varying positive semi-

definite matrix, and $t_f$ is the actual convergence time defined in Problem 1. Let $\hat{x}_i(t)$ and $\hat{u}_i(t)$ denote, respectively, the $i$th component of $\hat{x}(t) \triangleq (W \otimes I_{2n})[x(t) - x^0]$ and $\hat{u}(t) \triangleq (W \otimes I_{2n})u(t)$, where $W$ is defined in (1). The multi-agent system (5) can be written equivalently as

$$\dot{x}_i(t) = A\hat{x}_i(t) + B\hat{u}_i(t), \quad i = 1, \ldots, N,$$

where $A x^0_i = 0$, $i = 1, \ldots, N$, is used. Due to Assumption 1, $J(t_f, x(t_f))$ can be written equivalently as

$$J_i(t_f, \hat{x}_i(t_f)) = \sum_{i=1}^{N} J_i(t_f, \hat{x}_i(t_f)),$$

where

$$J_i(t_f, \hat{x}_i(t_f)) = \int_{0}^{t_f} \hat{u}_i^T(t) \hat{u}_i(t) dt,$$

$$J_i(t_f, \hat{x}_i(t_f)) = \int_{0}^{t_f} \{ \hat{u}_i^T(t) \hat{u}_i(t) + \lambda_i \beta \hat{x}_i^T(t) Q \hat{x}_i(t) \} dt$$

$$+ \alpha \left( \int_{0}^{t_f} \hat{x}_i^T(t) [\lambda_i I_{2n} + m_i S(t)] \hat{x}_i(t) dt \right.$$

$$+ \lambda_i \hat{x}_i^T(t_f) \hat{x}_i(t_f) \}, \quad i = 2, \ldots, N$$

with $m_i \triangleq \alpha (\lambda_i^2 - \sigma \lambda_i)$. It is straightforward to obtain that $\hat{u}_i^* \equiv 0$.

Next, the optimal input $\hat{u}_i^*$ is derived for $i = 2, \ldots, N$. Let $\hat{x}_i^*(t)$ denote the state of (11) under the optimal input $\hat{u}_i^*(t)$, i.e.,

$$\dot{\hat{x}}_i^*(t) = A\hat{x}_i^*(t) + B\hat{u}_i^*(t)$$

with the initial condition $\hat{x}_i^*(0) = \hat{x}_i^0$, where $\hat{x}_i^0$ is the $i$th component of $\hat{x}^0 = (W \otimes I_{2n})(x^0 - x^0)$. Consider a new input vector

$$\hat{u}_i(t) = \hat{u}_i^*(t) + \epsilon \hat{u}_i(t)$$

for (11), where $\hat{u}_i(t)$ is an arbitrary function of time, and $\epsilon \in \mathbb{R}$ is an arbitrary number. Due to the variation of the input vector, the state of the system (11) will change from $\hat{x}_i^*(t)$ to

$$\dot{x}_i(t) = \hat{x}_i(t) + \epsilon \dot{x}_i(t), \quad 0 \leq t \leq t_f,$$

where $\dot{x}_i(t)$ is some function of time. Substitution of (14) and (15) into (11) yields

$$\dot{\hat{x}}_i^*(t) + \epsilon \dot{x}_i(t) = A[\hat{x}_i^*(t) + \epsilon \dot{x}_i(t)] + B[\hat{u}_i^*(t) + \epsilon \hat{u}_i(t)].$$

Subtraction of (13) from (16) and cancelation of $\epsilon$ lead
to
\[ \dot{x}_i(t) = A\dot{x}_i(t) + B\dot{u}_i(t) \] (17)
with the initial condition \( \dot{x}_i(0) = 0 \). The solution of (17) is
\[ \dot{x}_i(t) = \int_0^t e^{A(t-\tau)}B\dot{u}_i(\tau)\,d\tau. \] (18)

Using (14) and (15), Equation (12) can be rewritten as a function related to \( \epsilon \), denoted by \( J_i(t_f, \dot{x}_i(t_f), \epsilon) \). Since \( \dot{u}_i^*(t) \) is the control input that minimizes \( J_i(t_f, \dot{x}_i(t_f), \epsilon) \), \( J_i(t_f, \dot{x}_i(t_f), \epsilon) \) must have a minimum at \( \epsilon = 0 \), which implies that the first derivative of \( J_i(t_f, \dot{x}_i(t_f), \epsilon) \) with respect to \( \epsilon \) should be zero at \( \epsilon = 0 \). It thus follows that
\[ \int_0^{t_f} \left\{ \dot{u}_i^*(t)\dot{x}_i^*(t) + \dot{x}_i^*(t) [\lambda_i\beta Q + \lambda_i\alpha I_{2n} + m_i\alpha S(t)] \times \dot{x}_i^*(t) \right\} \,dt + \lambda_i\alpha \dot{x}_i^*(t_f)\dot{x}_i^*(t_f) = 0. \] (19)

Substitution of (18) into (19) together with some rearrangements leads to
\[ \int_0^{t_f} \dot{u}_i^*(t) \left\{ \dot{u}_i^*(t) + B^T \int_0^{t_f} e^{A^T(\tau-t)} [\lambda_i\beta Q + \lambda_i\alpha I_{2n} + m_i\alpha S(\tau)] \dot{x}_i^*(\tau) \,d\tau + \lambda_i\alpha B^T e^{A^T(t_f-\tau)} \dot{x}_i^*(t_f) \right\} \,dt = 0. \] (20)

Let
\[ p_i(t) \triangleq \int_t^{t_f} e^{A^T(\tau-t)} [\lambda_i\beta Q + \lambda_i I_{2n} + m_i S(\tau)] \dot{x}_i^*(\tau) \,d\tau + \lambda_i\alpha B^T e^{A^T(t_f-\tau)} \dot{x}_i^*(t_f). \] (21)

Equation (20) can be written compactly as
\[ \int_0^{t_f} \dot{u}_i^*(t) \{ \dot{u}_i^*(t) + \alpha B^T p_i(t) \} \,dt = 0. \] (22)

Since (22) holds for all possible \( \dot{u}_i(t) \), it follows that
\[ \dot{u}_i^*(t) = -\alpha B^T p_i(t). \] (23)

Therefore, the problem of finding the optimal input \( \dot{u}_i^*(t) \) is transformed into the problem of finding the solution of \( p_i(t) \) that satisfies (21). Similar to the process of obtaining \( p_i(t) \) in [23], it can be shown that
\[ p_i(t) = \lambda_i P(t)\dot{x}_i^*(t), \] (24)
where \( P(t) \) is the solution to the following parametric differential Riccati equation (PDRE)
\[ \dot{P}(t) + I_{2n} + \frac{\beta}{\alpha} Q + A^T P(t) + P(t)A - \sigma P(t)BB^T P(t) = 0, \] (25)
\[ P(t_f) = I_{2n}, \]
where \( 0 < \sigma < \lambda_2 \). Substitution of (24) into (23) yields
\[ \dot{u}_i^*(t) = -\alpha \lambda_i B^T P(t)\dot{x}_i^*(t), \]
or equivalently
\[ u^*(t) = -\alpha [\mathcal{L} \otimes B^T P(t)] [x^*(t) - x^0]. \]

Let \( P \) be the solution to the following parametric algebraic Riccati equation (PARE)
\[ I_{2n} + \frac{\beta}{\alpha} Q + A^T P + P A - \sigma P B B^T P = 0. \] (26)

Since \((A, B)\) is stabilizable and \((A, I_{2n})\) is detectable, the solution to (25) converges to that of (26) as \( t_f \to \infty \). This leads to the optimal control input in the infinite-horizon case,
\[ \dot{u}_i^*(t) = -\alpha \lambda_i B^T P \dot{x}_i^*(t), \] (27)

or equivalently
\[ u^*(t) = -\alpha [\mathcal{L} \otimes B^T P] [x^*(t) - x^0]. \]

Substituting \( A = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \otimes I_n \) and \( B = \begin{bmatrix} 0 \\ 1 \end{bmatrix} \otimes I_n \) into (26), the solution \( P \) to (26) is given by
\[ P = \frac{1}{\sqrt{\sigma \alpha}} \begin{bmatrix} \sqrt{\sigma \alpha + \beta \alpha + 2\sqrt{\sigma \alpha}} & 1 \\ 1 & \sqrt{1 + \frac{\beta}{\alpha} + \frac{2}{\sqrt{\sigma \alpha}}} \end{bmatrix} \otimes I_n. \] (28)

The proof of the first part is thus completed.

2) Substituting the optimal control law (8) into the system (5) yields the following closed-loop system:
\[ \dot{x}^*(t) = (I_N \otimes A)x^*(t) - \alpha (\mathcal{L} \otimes B B^T P)[x^*(t) - x^0]. \] (29)
Define $V(x) = [x(t) - x^d]^T \left( I_N - \frac{1}{N} 11^T \right) \otimes P [x(t) - x^d]$, where $P$ is given by (28). Note that $V(x) = 0$ iff the formation is reached. It follows from (29) that

$$
\dot{V}(x^*) = 2[x^*(t) - x^d]^T \left( I_N - \frac{1}{N} 11^T \right) \otimes PA [x^*(t) - x^d]
- 2[x^*(t) - x^d]^T [\mathcal{L} \otimes \alpha PBB^T P] [x^*(t) - x^d].
$$

(30)

The first term in (30) can be written as

$$
2[x^*(t) - x^d]^T \left( I_N - \frac{1}{N} 11^T \right) \otimes PA [x^*(t) - x^d]
= 2[x^*(t) - x^d]^T (W^T W \otimes PA) [x^*(t) - x^d]
= 2 \sum_{i=2}^N [\tilde{x}_i^*(t)]^T PA \tilde{x}_i^*(t),
$$

(31)

where $W = \text{diag}([0,1,\ldots,1]) \in \mathbb{R}^{N \times N}$. Similarly, the second term can be rewritten as

$$
2[x^*(t) - x^d]^T [\mathcal{L} \otimes \alpha PBB^T P] [x^*(t) - x^d]
= 2 \sum_{i=2}^N \alpha \lambda_i [\tilde{x}_i^*(t)]^T PBB^T P \tilde{x}_i^*(t).
$$

(32)

Substituting (32) and (31) into (30) yields

$$
\dot{V}(x^*) = \sum_{i=2}^N [\tilde{x}_i^*(t)]^T [(A - \alpha \lambda_i \alpha B B^T P) P + P (A - \lambda_i \alpha B B^T P)] \tilde{x}_i^*(t)
- \sum_{i=2}^N \alpha \lambda_i [\tilde{x}_i^*(t)]^T PBB^T P \tilde{x}_i^*(t)
\leq - \sum_{i=2}^N \lambda_{\min}(P) \sum_{i=2}^N [\tilde{x}_i^*(t)]^T \tilde{x}_i^*(t),
$$

(33)

where the second equality is due to $(A - \alpha \lambda_i \alpha B B^T P) P + P (A - \lambda_i \alpha B B^T P) = A^T P - \sigma \alpha B B^T P + PA - \sigma \alpha B B^T P - 2 \alpha (\lambda_i - \sigma) B B^T P = - \left( I_{2n} + \frac{\sigma}{\alpha} Q + \alpha \sigma + 2 (\lambda_i - \sigma) \right) B B^T P$. Additionally,

$$
V(x^*) = [x^*(t) - x^d]^T \left( I_N - \frac{1}{N} 11^T \right) \otimes P [x^*(t) - x^d]
\geq \lambda_{\min}(P) \sum_{i=2}^N [\tilde{x}_i^*(t)]^T \tilde{x}_i^*(t).
$$

(34)

It follows from (33) and (34) that $\frac{\dot{V}(x^*)}{V(x^*)} \leq -\frac{1}{\lambda_{\min}(P)}$, which gives

$$
V(x^*(t)) \leq e^{-\frac{1}{\lambda_{\min}(P)} t} V(x(0)).
$$

(35)

Moreover, $V(x^*(t_f)) = \sum_{i=2}^N [\tilde{x}_i^*(t_f)]^T P \tilde{x}_i^*(t_f) \geq \lambda_{\min}(P) \sum_{i=2}^N \| \tilde{x}_i^*(t_f) \|^2 \geq \lambda_{\min}(P) (N - 1) \varepsilon^2$. By (35), the upper bound on the formation time is given by

$$
t_f \leq \frac{\lambda_{\min}(P) ln \frac{V(x(0))}{V(x^*(t_f))}}{\lambda_{\min}(P) (N - 1) \varepsilon^2}.
$$

Therefore, for the given steady-state error tolerance $\varepsilon$ and the termination time $T$, the formation task can be achieved if

$$
T \geq \frac{\lambda_{\min}(P) ln \frac{V(x(0))}{V(x^*(t_f))}}{\lambda_{\min}(P) (N - 1) \varepsilon^2},
$$

where by (28)

$$
\lambda_{\min}(P) = \frac{1}{2 \sqrt{\sigma \alpha}} \left[ \left( 1 + \sqrt{\sigma \alpha} \right) \sqrt{1 + \frac{\beta}{\alpha} + \frac{2}{\sigma \alpha}}
- \sqrt{1 + \sigma \alpha - 2 \sqrt{\sigma \alpha}} \left( 1 + \frac{\beta}{\alpha} + \frac{2}{\sqrt{\sigma \alpha}} \right) + 4 \right].
$$

(36)

Let $J_{E*}$ denote the energy consumption during $[0,T]$ under the optimal control law (8). Due to Assumption 1, $J_{E*}$ can be written as $J_{E*} = \sum_{i=2}^N J_{E_i}$, where

$$
J_{E_i} = \int_0^T \{ [\tilde{u}_i^*(t)]^T \tilde{u}_i^*(t) + \beta \lambda_i [\tilde{x}_i^*(t)]^T Q \tilde{x}_i^*(t) \} dt.
$$

It follows from (27) that

$$
J_{E_i} = \int_0^T [\tilde{x}_i^*(t)]^T (\alpha^2 \lambda_i^2 PBB^T P + \beta \lambda_i Q) \tilde{x}_i^*(t) dt
\leq [\alpha^2 \lambda_i^2 \lambda_{\max}(PBB^T P) + \beta \lambda_i] \int_0^T [\tilde{x}_i^*(t)]^T \tilde{x}_i^*(t) dt
\leq \left[ \lambda_N \left( \alpha + \frac{1}{\sigma} \right) \left( \alpha + \beta + 2 \sqrt{\frac{\alpha}{\sigma}} \right) + \beta \right] \lambda_i
\times \int_0^T [\tilde{x}_i^*(t)]^T \tilde{x}_i^*(t) dt.
$$

(36)

On the other hand, the solution of (13) is given by

$$
\tilde{x}_i^*(t) = e^{(A - \lambda_i \alpha B B^T P)t} \tilde{x}_i(0).
$$
It hence follows that \( J^*_E \) is given by
\[
\int_0^T \langle \tilde{x}_i(t) \rangle_t^T \tilde{x}_i(t) dt = \int_0^T \tilde{x}_i^T(0) \times e^{(A-\lambda_i\alpha\mathbf{B}^T\mathbf{P})t} e^{(A-\lambda_i\alpha\mathbf{B}^T\mathbf{P})t} \tilde{x}_i(0) dt \leq ||\tilde{x}_i(0)||^2 \int_0^T \|e^{(A-\lambda_i\alpha\mathbf{B}^T\mathbf{P})t}\|^2 dt. \]
Since
\[
\|e^{(A-\lambda_i\alpha\mathbf{B}^T\mathbf{P})t}\| \leq \max_{t \in \mathbb{I}} \|e^{(A-\lambda_i\alpha\mathbf{B}^T\mathbf{P})t}\|
\]

it follows that
\[
\int_0^T \langle \tilde{x}_i(t) \rangle_t^T \tilde{x}_i(t) dt 
\leq \|\tilde{x}_i(0)\|^2 \int_0^T e^{2\max_{t \in \mathbb{I}} \lambda_{\max}(A-\lambda_i\alpha\mathbf{B}^T\mathbf{P})t} dt
\]
\[
= \frac{2}{\max_{t \in \mathbb{I}} \lambda_{\max}(A-\lambda_i\alpha\mathbf{B}^T\mathbf{P})} \left(1 - e^{2\max_{t \in \mathbb{I}} \lambda_{\max}(A-\lambda_i\alpha\mathbf{B}^T\mathbf{P})T} \right). \]
(37)

It can be verified that
\[
\lambda_{\max}(A-\lambda_i\alpha\mathbf{B}^T\mathbf{P}) = \frac{1}{2} \left( -\lambda_i \sqrt{\frac{\alpha}{\sigma}} \left(1 + \frac{\beta}{\alpha} + \frac{2}{\sqrt{\sigma}}\right) + \sqrt{\lambda_i^2 \left(1 + \frac{\beta}{\alpha} + \frac{2}{\sqrt{\sigma}}\right) - 4\lambda_i \sqrt{\frac{\alpha}{\sigma}}} \right).
\]

Additionally,
\[
\lambda_i \|\tilde{x}_i(0)\|^2 
\leq \sum_{i=1}^N \lambda_i \|\tilde{x}_i(0)\|^2 
\leq \|x(0) - x^d\|^T (\mathcal{L} \otimes I_{2n})(x(0) - x^d).
\]
(38)

Combining (36), (37), and (38) leads to
\[
J^*_{E} \leq \frac{V_c(0)}{2} \max_{t \in \mathbb{I}} \lambda_{\max}(A-\lambda_i\alpha\mathbf{B}^T\mathbf{P}) \left(1 - e^{2\lambda_{\max}(A-\lambda_i\alpha\mathbf{B}^T\mathbf{P})T} \right), \]
(39)

where
\[
V_c(0) = \|x(0) - x^d\|^T (\mathcal{L} \otimes I_{2n})(x(0) - x^d).
\]

Let \( \text{Max}(\lambda) \) denote the parameter \( \lambda_i \) that maximizes \( \lambda_{\max}(A-\lambda_i\alpha\mathbf{B}^T\mathbf{P}) \). Eq. (39) can be written as
\[
J^*_{E} \leq \frac{V_c(0)\lambda_N(\alpha + \frac{\beta}{\sigma})(\alpha + \beta + 2\sqrt{\sigma}) + \beta}{2\lambda_{\max}(A-\lambda_i\alpha\mathbf{B}^T\mathbf{P})} \left(1 - e^{2\max_{t \in \mathbb{I}} \lambda_{\max}(A-\lambda_i\alpha\mathbf{B}^T\mathbf{P})T} \right) \times \left( -\frac{\beta}{\sigma} \left(1 + \frac{\beta}{\alpha} + \frac{2}{\sqrt{\sigma}}\right) \right).
\]
(40)

Since
\[
\lambda_{\max}(A-\lambda_i\alpha\mathbf{B}^T\mathbf{P}) = \frac{1}{2} \left( -\lambda_i \sqrt{\frac{\alpha}{\sigma}} \left(1 + \frac{\beta}{\alpha} + \frac{2}{\sqrt{\sigma}}\right) + \sqrt{\lambda_i^2 \left(1 + \frac{\beta}{\alpha} + \frac{2}{\sqrt{\sigma}}\right) - 4\lambda_i \sqrt{\frac{\alpha}{\sigma}}} \right)
\]

it follows that
\[
\lambda_{\max}(A-\lambda_i\alpha\mathbf{B}^T\mathbf{P}) 
\leq 1 - e^{2\lambda_{\max}(A-\lambda_i\alpha\mathbf{B}^T\mathbf{P})T} \leq 1 - e^{-\lambda_N \sqrt{\frac{\beta}{\sigma}} \left(1 + \frac{\beta}{\alpha} + \frac{2}{\sqrt{\sigma}}\right) T}. \]
(41)

Combining (40) and (41) leads to
\[
J^*_{E} \leq \frac{V_c(0)\lambda_N(\alpha + \frac{\beta}{\sigma})(\alpha + \beta + 2\sqrt{\sigma}) + \beta}{2\lambda_{\max}(A-\lambda_i\alpha\mathbf{B}^T\mathbf{P})} \left(1 - e^{2\lambda_{\max}(A-\lambda_i\alpha\mathbf{B}^T\mathbf{P})T} \right) \times \left( -\frac{\beta}{\sigma} \left(1 + \frac{\beta}{\alpha} + \frac{2}{\sqrt{\sigma}}\right) \right). \]
(42)

which holds by multiplying the numerator and denominator with \( \sqrt{\lambda N} \frac{\beta}{\sigma} \left(1 + \frac{\beta}{\alpha} + \frac{2}{\sqrt{\sigma}}\right) - 4\lambda(\lambda) \sqrt{\frac{\alpha}{\sigma}} + \).
Max(λ)\sqrt{\frac{\alpha}{\sigma}}\left(1 + \frac{\beta}{\alpha} + \frac{2}{\sqrt{\sigma \alpha}}\right). Additionally, 

$$\sqrt{\text{Max}^2(\lambda)\frac{\alpha}{\sigma}}\left(1 + \frac{\beta}{\alpha} + \frac{2}{\sqrt{\sigma \alpha}}\right) - 4\text{Max}(\lambda)\sqrt{\frac{\alpha}{\sigma}}$$

$$+ \text{Max}(\lambda)\sqrt{\frac{\alpha}{\sigma}}\left(1 + \frac{\beta}{\alpha} + \frac{2}{\sqrt{\sigma \alpha}}\right) \leq 2\text{Max}(\lambda)\sqrt{\frac{\alpha}{\sigma}}\left(1 + \frac{\beta}{\alpha} + \frac{2}{\sqrt{\sigma \alpha}}\right). \quad (43)$$

Substituting (43) into (42) yields

$$J_{\tilde{E}_1} \leq \frac{V_C(\lambda)[\lambda_N(\alpha + \frac{1}{\alpha})(\alpha + \beta + 2\sqrt{\frac{2}{\sigma}}) + \beta]}{4\text{Max}(\lambda)\sqrt{\frac{\alpha}{\sigma}}\left(1 + \frac{\beta}{\alpha} + \frac{2}{\sqrt{\sigma \alpha}}\right)}.$$ 

The energy constraint is given by $J_{\tilde{E}_1} \leq E_i(0)$. Thus, the energy requirement can be met if

$$E_i(0) \geq \frac{1}{2}V_C(\lambda)[\lambda_N(\alpha + \frac{1}{\alpha})(\alpha + \beta + 2\sqrt{\frac{2}{\sigma}}) + \beta] \sqrt{1 + \frac{\beta}{\alpha} + \frac{2}{\sqrt{\sigma \alpha}}}, \quad i \in \{1, \ldots, N\}.$$ 

The proof is thus completed.

According to Theorem 1, if the time constraint is removed, i.e., $T \to \infty$, the energy bound can be simplified as $E_i(0) \geq \frac{1}{2}V_C(\lambda)[\lambda_N(\alpha + \frac{1}{\alpha})(\alpha + \beta + 2\sqrt{\frac{2}{\sigma}}) + \beta] \sqrt{1 + \frac{\beta}{\alpha} + \frac{2}{\sqrt{\sigma \alpha}}}, \quad i \in \{1, \ldots, N\}$. Additionally, it is noted that if the initial formation error is large, a longer termination time $T$ and a higher energy level $E_i(0)$ are expected for achieving the formation of the multi-agent system. Besides, the smaller the formation threshold $\varepsilon$, the longer the termination time and the more the energy consumption.

4 Monotonicity properties of the optimal formation algorithm

This section is devoted to the discussion of the relationships between the lower bound of the required initial energy $E_i(0)$, the lower bound of the achievable termination time $T$, and the algorithm parameters.

4.1 Monotonicity of the PARE solution

The following result presents the monotonicity of the solution $P$ of the PARE (26) with respect to the parameters $\alpha$, $\sigma$, and $\beta$.

**Theorem 2** The solution $P$ of the PARE (26) is a decreasing function of $\alpha$ and $\sigma$, and an increasing function of $\beta$, i.e.,

$$\frac{\partial P}{\partial \alpha} \leq 0, \quad \frac{\partial P}{\partial \sigma} \leq 0, \quad \frac{\partial P}{\partial \beta} \geq 0, \quad \forall \alpha, \sigma, \beta > 0.$$

**Proof 2** It follows from (26) that

$$(A - \alpha \sigma BB^T P)^T P + P(A - \alpha \sigma BB^T P) = -\left(I_{2n} + \frac{\beta}{\alpha} Q + \alpha PBB^T P\right). \quad (44)$$

Since $I_{2n} + \frac{\beta}{\alpha} Q + \alpha PBB^T P$ is positive definite, it follows from (44) that $(A - \alpha \sigma BB^T P)$ is Hurwitz. To show the relationship between $P$ and $\alpha$, differentiating both sides of (44) with respect to $\alpha$ yields

$$\frac{\partial P}{\partial \alpha} (A - \alpha \sigma BB^T P) + (A - \alpha \sigma BB^T P)^T \frac{\partial P}{\partial \alpha} = \sigma PBB^T P + \frac{\beta}{\alpha^2} Q. \quad (45)$$

Since $(A - \alpha \sigma BB^T P)$ is Hurwitz, and the right-hand side of (45) is positive semidefinite, (45) has the following unique solution

$$\frac{\partial P}{\partial \alpha} = -\int_0^\infty e^{(A - \alpha \sigma BB^T P)t} \left(\sigma PBB^T P + \frac{\beta}{\alpha^2} Q\right) \times e^{(A - \alpha \sigma BB^T P)t} dt \leq 0.$$ 

Thus, $P$ is monotonically decreasing with $\alpha$. Similarly, it can be shown that

$$\frac{\partial P}{\partial \sigma} (A - \alpha \sigma BB^T P) + (A - \alpha \sigma BB^T P)^T \frac{\partial P}{\partial \sigma} = \alpha PBB^T P,$$
which has the following unique solution
\[
\frac{\partial P}{\partial \sigma} = -\int_0^\infty e^{(A-\alpha BB^T P)^T t} \alpha PBB^T Pe^{(A-\alpha BB^T P)^T t} dt \leq 0.
\]

Similarly, it can be shown that
\[
\frac{\partial P}{\partial \beta}(A-\alpha BB^T P) + (A-\alpha BB^T P)^T \frac{\partial P}{\partial \beta} = -\frac{1}{\alpha} Q,
\]
which has the unique solution
\[
\frac{\partial P}{\partial \beta} = \int_0^\infty e^{(A-\alpha BB^T P)^T t} \frac{1}{\alpha} Q e^{(A-\alpha BB^T P)^T t} dt \geq 0.
\]

Thus, $P$ is monotonically decreasing with $\sigma$ and monotonically increasing with $\beta$. The proof is thus completed.

4.2 Termination time

The following result discusses the monotonicity of the lower bound of the termination time $T$ in (9).

**Theorem 3** The lower bound of the achievable termination time $T$ in (9) is a decreasing function of both $\sigma$ and $\alpha$ and an increasing function of $\beta$.

**Proof 3** For notational convenience, define the lower bound of the termination time $T$ as $T_l$, i.e.,
\[
T_l = \lambda_{\min}(P) \ln \frac{V(x(0))}{\lambda_{\min}(P)(N-1)\varepsilon^2}. \tag{46}
\]

Differentiating both sides of (46) with respect to $\alpha$ yields
\[
\frac{\partial T_l}{\partial \alpha} = \frac{\partial \lambda_{\min}(P)}{\partial \alpha} \left( \ln \frac{V(x(0))}{\lambda_{\min}(P)(N-1)\varepsilon^2} - 1 \right) + \frac{\lambda_{\min}(P) \partial V(x(0))}{V(x(0))}. \tag{47}
\]

It is straightforward to know that $\frac{\partial T_l}{\partial \alpha} \leq 0$ if the two terms on the right-hand side of (47) are non-positive. According to the relationship of $P$ and $\alpha$, it follows that
\[
\frac{\partial V(x(0))}{\partial \alpha} \leq 0.
\]

Since $P$ is symmetric and positive semidefinite, it can be diagonalized as
\[
P = M^T \Lambda(P) M, \tag{48}
\]
where $M = [m_1, \ldots, m_{2n}]$ is the matrix comprising the orthonormal eigenvectors of $P$ and $\Lambda(P) = \text{diag}([\lambda_1(P), \ldots, \lambda_{2n}(P)])$ with $\lambda_i(P)$ being the $i$th eigenvalue of $P$.

Differentiating both sides of (48) with respect to $\alpha$ yields
\[
\frac{\partial P}{\partial \alpha} = \frac{\partial M^T}{\partial \alpha} (\Lambda(P) M) + M^T \frac{\partial (\Lambda(P) M)}{\partial \alpha} = 0 + M^T \frac{\partial (\Lambda(P) M)}{\partial \alpha} + \Lambda(P) \frac{\partial M}{\partial \alpha} = M^T \frac{\partial \Lambda(P)}{\partial \alpha} M.
\]

Since $\frac{\partial P}{\partial \alpha} \leq 0$, each eigenvalue of $\frac{\partial P}{\partial \alpha}$ must be non-positive, i.e.,
\[
\frac{\partial \lambda_i(P)}{\partial \alpha} \leq 0, \quad i \in \{1, \ldots, 2n\},
\]
which gives $\frac{\partial \lambda_{\min}(P)}{\partial \alpha} \leq 0$. Additionally,
\[
\ln \frac{V(x(0))}{\lambda_{\min}(P)(N-1)\varepsilon^2} - 1 \geq \ln \frac{\lambda_{\min}(P) \sum_{i=2}^N \|\tilde{x}_i(0)\|^2}{\lambda_{\min}(P)(N-1)\varepsilon^2} - 1 = \ln \frac{\sum_{i=2}^N \|\tilde{x}_i(0)\|^2}{(N-1)\varepsilon^2} - 1 \geq 0,
\]
which leads to $\frac{\partial T_l}{\partial \alpha} \leq 0$. Similarly, it can be shown that $\frac{\partial T_l}{\partial \beta} \geq 0$.

The proof is thus completed.

4.3 Energy expenditure

Next, the effect of the parameters $\alpha$, $\sigma$, and $\beta$ on the lower bound of the energy level $E_i(0)$ in (10) is investigated. The following assumption is made in this subsection.

**Assumption 2** Suppose that
\[
\lambda_N \left( \frac{3}{2} \alpha + \frac{1}{2} \beta + 2 \sqrt{\frac{\alpha}{\sigma} + \frac{1}{2\sigma} - \frac{\beta}{2\alpha}} \right) - \frac{\beta}{2\alpha} \geq 0,
\]
where $\lambda_N$ denotes the largest eigenvalue of the Laplacian matrix.

**Theorem 4** If Assumption 2 holds, then the lower bound of the required initial energy $E_i(0)$ in (10) is an increasing function of $\alpha$ and $\beta$ and a decreasing function of $\sigma$.

**Proof 4** For notational convenience, define the lower
bound of $E_i(0)$ as $E_i$, i.e.,

$$E_i = \frac{1}{2} V_L(0) \left[ \lambda_N \left( \alpha + \frac{1}{\sigma} \right) \left( \alpha + \beta + 2 \sqrt{\frac{\alpha}{\sigma}} \right) + \beta \right] \times \left( 1 + \frac{\beta}{\alpha} + \frac{2}{\sqrt{\alpha \sigma}} \right) e^{-\lambda_N \sqrt{\frac{1}{2} \left( \frac{1}{\alpha} + \frac{1}{\sigma} \right) T}}. \quad (49)$$

Differentiating both sides of (49) with respect to $\alpha$ yields

$$\frac{\partial E_i}{\partial \alpha} = \frac{\partial H_1}{\partial \alpha} V_L(0) H_2 + \frac{\partial H_2}{\partial \alpha} V_L(0) H_1, \quad (50)$$

where $H_1 = \left[ \lambda_N \left( \alpha + \frac{1}{\sigma} \right) \left( \alpha + \beta + 2 \sqrt{\frac{\alpha}{\sigma}} \right) + \beta \right] \left( 1 + \frac{\beta}{\alpha} + \frac{2}{\sqrt{\alpha \sigma}} \right)$, $H_2 = \frac{1}{2} \left( 1 - e^{-\lambda_N \sqrt{\frac{1}{2} \left( \frac{1}{\alpha} + \frac{1}{\sigma} \right) T}} \right)$.

$$\frac{\partial H_1}{\partial \alpha} = \lambda_N \left( 2 \alpha + \beta + 3 \sqrt{\frac{\alpha}{\sigma}} + \frac{1}{\sqrt{\alpha \sigma}} \right) \left( 1 + \frac{\beta}{\alpha} + \frac{2}{\sqrt{\alpha \sigma}} \right) \left[ \lambda_N \left( \alpha + \frac{1}{\sigma} \right) \left( \alpha + \beta + 2 \sqrt{\frac{\alpha}{\sigma}} \right) + \beta \right] \left[ 1 + \frac{2}{\sqrt{\alpha \sigma}} \right]$$

$$\frac{\partial H_2}{\partial \alpha} = \lambda_N T \left( 1 + \frac{2}{\sqrt{\alpha \sigma}} \right) e^{-\lambda_N \sqrt{\frac{1}{2} \left( \frac{1}{\alpha} + \frac{1}{\sigma} \right) T}}. \quad (51)$$

can be seen that $\frac{\partial H_1}{\partial \alpha} \geq 0$ when the two terms on the right-hand side of (50) are non-negative. Since $V_L(0) \geq 0$, $H_1 \geq 0$, $H_2 \geq 0$, and $\frac{\partial H_2}{\partial \alpha} \geq 0$, the second term of (50) is non-negative. In the following, the sign of $\frac{\partial H_1}{\partial \alpha}$ is discussed. It follows that

$$\frac{\partial H_1}{\partial \alpha} \geq \lambda_N \left( 2 \alpha + \beta + 3 \sqrt{\frac{\alpha}{\sigma}} + \frac{1}{\sqrt{\alpha \sigma}} \right) \left[ \lambda_N \left( \alpha + \frac{1}{\sigma} \right) \left( \alpha + \beta + 2 \sqrt{\frac{\alpha}{\sigma}} \right) + \beta \right] \left[ 1 + \frac{2}{\sqrt{\alpha \sigma}} \right]$$

which leads to $\frac{\partial H_1}{\partial \alpha} \geq 0$, which gives $\frac{\partial E_i}{\partial \alpha} \geq 0$. Thus, the lower bound of the required initial energy $E_i(0)$ is a decreasing function of $\alpha$. Similarly, it can be shown that

$$\frac{\partial E_i}{\partial \sigma} = V_L(0) \frac{\partial H_1}{\partial \sigma} H_2 + V_L(0) \frac{\partial H_2}{\partial \sigma} H_1,$$

where

$$\frac{\partial H_1}{\partial \sigma} = -\frac{\lambda_N}{\sigma^2} \left( \alpha + \beta + 3 \sqrt{\frac{\alpha}{\sigma}} + \frac{1}{\sqrt{\alpha \sigma}} \right) \left( 1 + \frac{\beta}{\alpha} + \frac{2}{\sqrt{\alpha \sigma}} \right)$$

$$\frac{\partial H_2}{\partial \sigma} = \frac{\lambda N T \left( 1 + \frac{2}{\sqrt{\alpha \sigma}} \right)}{4 \sqrt{\frac{1}{2} \left( \frac{1}{\alpha} + \frac{1}{\sigma} \right) T}} e^{-\lambda_N \sqrt{\frac{1}{2} \left( \frac{1}{\alpha} + \frac{1}{\sigma} \right) T}} \leq 0,$$

which further leads to $\frac{\partial E_i}{\partial \sigma} \leq 0$. Also, one has $\frac{\partial E_i}{\partial \beta} = V_L(0) \frac{\partial H_1}{\partial \beta} H_2 + V_L(0) \frac{\partial H_2}{\partial \beta} H_1$, and

$$\frac{\partial H_1}{\partial \beta} = \left[ \lambda_N \left( \alpha + \frac{1}{\sigma} \right) + 1 \right] \left( 1 + \frac{\beta}{\alpha} + \frac{2}{\sqrt{\alpha \sigma}} \right)$$

$$\frac{\partial H_2}{\partial \beta} = \frac{\lambda N T \left( 1 + \frac{2}{\sqrt{\alpha \sigma}} \right)}{4 \sqrt{\frac{1}{2} \left( \frac{1}{\alpha} + \frac{1}{\sigma} \right) T}} e^{-\lambda_N \sqrt{\frac{1}{2} \left( \frac{1}{\alpha} + \frac{1}{\sigma} \right) T}} \geq 0,$$

which leads to $\frac{\partial E_i}{\partial \beta} \geq 0$. Thus, the lower bound of the required initial energy $E_i(0)$ is a decreasing function of $\sigma$ and an increasing function of $\beta$. The proof is hence completed.

It follows from Theorems 3 and 4 that the lower bounds on the achievable termination time and the required initial energy are both decreasing functions of $\sigma$. Hence, one can increase the value of $\sigma$ to reduce the formation time and the energy consumption. However, $\sigma$ is not allowed to be arbitrarily large, because the condition $\sigma < \sigma_2$ must be met as indicated by Theorem 1. Meanwhile, a large value of $\alpha$ is capable of speeding the convergence of the formation algorithm, yet at the cost of more energy consumption. Finally, the resistance coefficient $\beta$ is both harmful to convergence time as well as energy consumption. That is, a larger value of $\beta$ will lead to a longer convergence time and more energy consumption.

5 Simulation

In this section, numerical examples are presented to verify the theoretical results. Let $N = 5$ and $n = 2$. The ini-
Fig. 1. The network topology

The values of the parameters are given by $x_1(0) = (0, 4, 0, 0)$, $x_2(0) = (12, 9, 0, 0)$, $x_3(0) = (5, 3, 0, 0)$, $x_4(0) = (9, 3, 0, 0)$, and $x_5(0) = (4, 0, 0, 0)$. The desired relative states are set to $d_{21} = (5, -2.5, 0, 0)$, $d_{32} = (5, 2.5, 0, 0)$, $d_{34} = (-5, 2.5, 0, 0)$, $d_{14} = (-5, -2.5, 0, 0)$, $d_{15} = (5, 0, 0, 0)$, and $d_{23} = (5, 0, 0, 0)$. The initial energy levels are given by $E(0) = \{1000, 1200, 700, 900, 500\}$, the termination time is $T = 3s$, and the steady-state error tolerance is $\varepsilon = 0.1$. The network topology is given in Fig. 1, for which the eigenvalues of the Laplacian matrix $\mathcal{L}$ are $\text{spec}(\mathcal{L}) = \{0, 1.382, 1.382, 3.618, 3.618\}$, and the second smallest eigenvalue is $\lambda_2 = 1.382$.

Table 1 shows three sets of the values of $\alpha$, $\sigma$, and $\beta$. Only the first set satisfies the energy and time constraints, i.e., Eqs. (9) and (10), simultaneously. The second set violates the termination time constraint (9), while the third set violates the energy constraint (10). Fig. 4 depicts the final formation shape of the multi-agent system in each case. Fig. 5 shows the energy consumption of the agents during the formation task. It can be observed that in the first case, the formation is achieved and the energy is not exhausted for each agent; in the second case, the formation task is not accomplished by the end of the termination time $T = 3s$; in the third case, the energy of agent 4 is exhausted before the formation mission is accomplished.

### 6 Conclusions

This paper presents a globally optimal distributed formation control algorithm and a comprehensive analysis of the roles of energy levels, termination time, control parameters, as well as the network topology on achieving energy and time constrained formation control. Two lower bounds on the required initial energy levels and on the achievable termination time are explicitly given, which help answer the question whether a distributed formation control problem is feasible under prescribed hard constraints on the termination time and energy expenditure. Additionally, several monotonicity properties in relation to the control parameters, in particular, the achievable termination time and the required initial energy with respect to those control parameters are derived. These properties can be properly exploited to facilitate the formation control design. The formulation of this paper provides a solution to LQR-based formation control under constraints of both termination time and energy. The future topic can be directed to nonlinear agent dynamics and directed network topologies.
