BILINEAR HILBERT TRANSFORMS ASSOCIATED TO PLANE CURVES

JINGWEI GUO  LECHAO XIAO

Abstract. We prove that the bilinear Hilbert transforms and maximal functions along certain general plane curves are bounded from $L^2(\mathbb{R}) \times L^2(\mathbb{R})$ to $L^1(\mathbb{R})$.

1. Introduction

Since the initial breakthroughs for singular integrals along curves and surfaces by Nagel, Rivi`ere, Stein, Wainger, et al., in the 1970s (see for example [14] and [16] for some of their works on Hilbert transforms along curves), extensive research in this area of harmonic analysis has been done and a great many fascinating and important results have been established, which culminate in a general theory of singular Radon transforms (see for instance Christ, Nagel, Stein, and Wainger [2]).

Another attractive area, parallel to the above one, is the bilinear extension of the classical Hilbert transform. The boundedness of such bilinear transforms was conjectured by Calderón and motivated by the study of the Cauchy integral on Lipschitz curves. In the 1990s, this conjecture was verified by Lacey and Thiele in a breakthrough pair of papers [8, 9]. In their works, a systematic and delicate method was developed, inspired by the famous works of Carleson [1] and Fefferman [3], which is nowadays referred as the method of time-frequency analysis. Over the past two decades, this method has merged as a powerful analytic tool to handle problems that are related to multilinear analysis.

We are interested in the study of bilinear/multilinear singular integrals along curves and surfaces—a problem that is closely related to the two areas above. (We refer the readers to Li [11] for connections of this problem with ergodic theory and multilinear oscillatory integrals.) To begin with, we consider a model case—the truncated bilinear Hilbert transforms along plane curves. One formulation of the problem is as follows.

2010 Mathematics Subject Classification. Primary 42B20. Secondary 47B38.

Key words and phrases. bilinear Hilbert transforms, bilinear maximal functions, plane curves.
Let \( \Gamma(t) = (t, \gamma(t)) : (-1, 1) \to \mathbb{R}^2 \) be a curve in \( \mathbb{R}^2 \). To \( \Gamma \) we associate the truncated bilinear Hilbert transform operator \( H_\Gamma \) given by the principal value integral

\[
H_\Gamma(f, g)(x) = \int_{-1}^{1} f(x - t)g(x - \gamma(t))t^{-1} \, dt \quad (x \in \mathbb{R}),
\]

where \( f \) and \( g \) are Schwartz functions on \( \mathbb{R} \). When the function \( \gamma \) has certain curvature (or “non-flat”) conditions, the boundedness properties of this operator (e.g. whether it is bounded from \( L^{p_1}(\mathbb{R}) \times L^{p_2}(\mathbb{R}) \) to \( L^{r}(\mathbb{R}) \) for certain \( p_1, p_2, \) and \( r \)) are of great interest to us.

Li [11] studied such an operator (the integral defining \( H_\Gamma(f, g)(x) \) in [11] is over \( \mathbb{R} \)) with the curve being defined by a monomial (i.e. \( \gamma(t) = t^d, d \in \mathbb{N}, d \geq 2 \)) and proved that it is bounded from \( L^2(\mathbb{R}) \times L^2(\mathbb{R}) \) to \( L^1(\mathbb{R}) \). In his proof, he combined results and tools from both time-frequency analysis and oscillatory integral theory and used ingeniously a uniformity concept (the so-called \( \sigma \)-uniformity; see [11, Section 6]). Lie [13] improved Li’s results both qualitatively, by extending monomials to more general curves (certain “slow-varying” curves with extra curvature assumptions), and quantitatively, by improving the estimates. Instead of using Li’s method of \( \sigma \)-uniformity, Lie used a Gabor frame decomposition to discretize certain operators in a smart way and then worked with the discretized operators which have variables separated on the frequency side and preserve certain main characteristics (see the appendix of [13] for a detailed comparison between their methods).

Another interesting aspect of this problem was considered by Li and the second author [12], in which they studied the case when the curve is defined by a polynomial with different emphasis of getting bounds uniform in coefficients of the polynomial and the full range of indices \( (p_1, p_2, r) \). They provided complete answers (except to the endpoint case) for \( H_\Gamma \) when the polynomial is “non-flat” near the origin (i.e. without the linear term). When the polynomial has a linear term, however, the full range of indices for the corresponding uniform estimates is extremely difficult to find and remains open.

In this paper we consider a family of general curves and provide an easy-to-check criterion for a curve whose associated bilinear Hilbert transform is bounded from \( L^2(\mathbb{R}) \times L^2(\mathbb{R}) \) to \( L^1(\mathbb{R}) \) (for the precise statement of our results, see Section 2). We use the methods that are used in Li [11] (with modifications). Although we use different methods from Lie [13], the curves we consider are similar and the estimates we get are the same.

Our criterion, motivated by results in Lie [13] and Nagel, Vance, Wainger, and Weinberg [15], mainly asks one to check whether certain bounds of various expressions involving derivatives of a quotient are satisfied. In [13] a simple necessary and sufficient condition is provided (among other results) for the \( L^2 \)-boundedness of the Hilbert transform along the curve \( \Gamma \) with an odd function \( \gamma \) and it is expressed in terms of an auxiliary function \( h(t) = t\gamma'(t) - \gamma(t) \). Both Lie’s and our results indicate that an appropriate replacement for \( h \) in the bilinear setting might be in
the form of a quotient (see the \( Q_\epsilon(t) \) defined in Section 2). We still do not know whether our criterion is a necessary condition.

In our main estimates in Section 4, we apply the \( TT^* \) method both in frequency space (with an extra size restriction \(|\gamma'(2^{-j})| > 2^{-m}\)) and in time space (with an extra restriction on the function space), then we combine both results to get the fast decay needed in proving the boundedness of the desired operator. Since we are considering general curves, we pay special attention to the dependence (on \( \gamma, j, m, \) etc.) of all bounds we get, especially to those occurring when we apply a quantitative version of the method of stationary phase.

We also establish analogous results for the bilinear maximal function along \( \Gamma \) (defined below) by using the arguments from [12, Section 7] and our main estimates.

\[
M\Gamma(f,g)(x) = \sup_{0<\epsilon<1} \epsilon^{-1} \int_0^{\epsilon} |f(x-t)g(x-\gamma(t))| \, dt \quad (x \in \mathbb{R}).
\]

We note that such an operator along a “non-flat” polynomial was already carefully studied in [12]. Much deeper and more elegant results for a linear curve can be found in Lacey [7].

Notations: The Fourier transform of \( f \) is \( \hat{f}(\xi) = \mathcal{F}[f](\xi) = \int_{\mathbb{R}} f(x) e^{-2\pi i \xi x} \, dx \) and its inverse Fourier transform is \( \mathcal{F}^{-1}[g](x) = \int_{\mathbb{R}} g(\xi) e^{2\pi i \xi x} \, d\xi \). Let \( 1_{a,n} \) be the indicator function of interval \( a \cdot [n, n+1) \) for \( a, n \in \mathbb{R} \) and \( 1_I \) the indicator function of interval \( I \). The indices \( (p_1, p_2, r) \) are always assumed to satisfy \( 1/p_1 + 1/p_2 = 1/r \), \( p_1 > 1, p_2 > 1 \), and \( r > 1/2 \). We use \( C \) to denote an absolute constant which may be depending on the curve and different from line to line.

2. Statement of theorems

For any \( a \in \mathbb{R} \), we say that a curve \( \Gamma(t) = (t, \gamma(t) + a) : (1, 1) \to \mathbb{R}^2 \) belongs to a family of curves, \( \mathcal{F}(-1,1) \), if the function \( \gamma \) satisfies the following conditions (2.1)-(2.4). There exists a constant \( 0 < A_1 < 1/2 \) such that on \( (-A_1, A_1) \setminus \{0\} \) the function \( \gamma \) is of class \( C^5 \) \( (N \geq 5) \) and \( \gamma' \neq 0 \). Let \( Q_\epsilon(t) = \gamma(\epsilon t) / \epsilon \gamma'(\epsilon) \). For \( 0 < |\epsilon| < c_0 < A_1/4 \) and \( 1/4 \leq |t| \leq 4 \), we have

\[
|D^j Q_\epsilon(t)| \leq C_1, \quad 0 \leq j \leq N,
\]

(2.1)

\[
|D^2 Q_\epsilon(t)| \geq c_1,
\]

(2.2)

\(^1\)In the problems considered in this paper, we can always remove the constant \( a \) from the definition of \( \Gamma \) by a translation argument, hence there is no need to specify the dependence of \( \Gamma \) on \( a \) and we will always let \( a = 0 \).
\[ |(D^2 Q_\epsilon)^2(t) - D^1 Q_\epsilon(t) D^3 Q_\epsilon(t)| \geq c_2, \quad \text{if } |\gamma'(\epsilon)| \leq K_1|\epsilon|^{-c_1}, \]

or

\[ 2(D^2 Q_\epsilon)^2(t) - D^1 Q_\epsilon(t) D^3 Q_\epsilon(t) \geq c_3, \quad \text{if } |\gamma'(\epsilon)| \geq K_2|\epsilon|^{-c_1}. \]

Let \( \Delta_j = |2^{-j}\gamma'(2^{-j})|^{-1} \). If \( \gamma''(\epsilon) \gamma'(\epsilon) < 0 \) for \( 0 < \epsilon < c_0 \), then there exist \( K_3 \in \mathbb{Z} \) and \( K_4 \in \mathbb{N} \) such that

\[ \Delta_j + K_3 \geq 2\Delta_j, \quad \text{if } j \geq K_4. \]

**Theorem 2.1.** If \( \Gamma \in L^2(\mathbb{R}) \times L^2(\mathbb{R}) \to L^1(\mathbb{R}) \), then \( H_\Gamma(f,g) \) can be extended to a bounded operator from \( L^2(\mathbb{R}) \times L^2(\mathbb{R}) \to L^1(\mathbb{R}) \).

The analogous version for bilinear maximal functions is as follows.

**Theorem 2.2.** If \( \Gamma \in L^2(\mathbb{R}) \times L^2(\mathbb{R}) \to L^1(\mathbb{R}) \), then \( M_\Gamma(f,g) \) is a bounded operator from \( L^2(\mathbb{R}) \times L^2(\mathbb{R}) \to L^1(\mathbb{R}) \).

**Remark 2.3.** Combining the results in this paper with the time-frequency analysis arguments in [12], the \( L^p(\mathbb{R}) \times L^p(\mathbb{R}) \to L^r(\mathbb{R}) \) boundedness of \( H_\Gamma \) and \( M_\Gamma \) for \( r < 1 \) may be obtained. We do not carry the details out in this paper. The lower bound of such \( r \), as indicated in [12] Theorem 4, is closely related to the decay rate of the following sublevel set estimates

\[ |\{|t| < 1 : |\gamma'(t) - 1| < \epsilon\}|, \]

as \( \epsilon \to 0^+ \). In particular, if \( \gamma'' \) is controlled by \( c_\nu h^\nu \) for some \( \nu > 0 \) and \( c_\nu > 0 \), then \( H_\Gamma \) and \( M_\Gamma \) are expected to be bounded from \( L^p(\mathbb{R}) \times L^{p'}(\mathbb{R}) \to L^\nu(\mathbb{R}) \) given \( r \geq \max\{1/(1 + \nu), 1/2\} \); see [12] Theorem 4 when \( \gamma \) is a polynomial.

**Remark 2.4.** (1) We will use \( A_1, c_0, c_1, c_2, c_3, C_1, K_1, K_2, K_3, \) and \( K_4 \) throughout this paper.

(2) The condition \( (2.1) \) with \( j = 1 \) implies that

\[ |D^1 Q_\epsilon(t)| \geq 1/C_1, \quad \text{for } 0 < |\epsilon| < \epsilon_0/4, 1/4 \leq |t| \leq 4. \]

(3) If \( \gamma''(\epsilon) \gamma'(\epsilon) > 0 \) for \( 0 < \epsilon < \epsilon_0 \), then \( (2.4) \) always holds with \( K_3 = 1 \).

(4) We now compare our assumptions \( (2.1)-(2.4) \) with Lie’s assumptions (1)-(5) in [13] P. 3. The \( (2.1) \) implies Lie’s (1). The \( (2.1) \) and \( (2.2) \) correspond to Lie’s (2) and (4) (the \( Q'' \) part) while the \( (2.3) \) essentially corresponds to Lie’s (5).

(5) Note that the curves considered here are not necessarily differentiable at the origin (they can even have a pole). One explanation for this phenomenon is that the bilinear Hilbert transform possesses certain symmetry between its two functions \( f \)

\[ \text{or} \]

\[ |\gamma'(\epsilon)| \geq K_3|\epsilon|^{-c_1}, \quad \text{for } 0 < |\epsilon| < \epsilon_0. \]

See also Lie [13] P. 4 Observation (6) and (7).
and $g$ (as well as its two variables $\xi$ and $\eta$ on the frequency side) that we can take advantage of to essentially transfer the case with a pole to the case without a pole (see the two expressions of $B_{j,m}^\varphi(f,g)$ at the beginning of Section 4).

Remark 2.5. Here are some curves $\Gamma(t) = (t, \gamma(t))$ that belong to $\mathcal{F}(-1, 1)$:

1. Those smooth curves that have contact with $t$-axis at the origin of finite order $\geq 2$ (namely, $\gamma(0) = \gamma'(0) = \ldots = \gamma^{(d-1)}(0) = 0$, but $\gamma^{(d)}(0) \neq 0$ for some natural number $d \geq 2$), for example, $\gamma(t) = t^d$ if $d \geq 2$;
2. The function $\gamma$ has a pole at the origin of finite order $\geq 1$ (namely, $\gamma(t) = t^{-n}h(t)$ for some natural number $n \geq 1$ and some smooth function $h$ with $h(0) \neq 0$);
3. $\gamma(t)$ is a linear combination of finitely many terms of the form $|t|^{\alpha} \log|t|^{\beta}$ for $\alpha, \beta \in \mathbb{R}$ and $\alpha \neq 0, 1$;
4. $\gamma(t) = \text{sgn}(t)|t|^{\alpha}$ or $|t|^{\alpha} \log|t|^{\beta}$ for $\alpha, \beta \in \mathbb{R}$ and $\alpha \neq 0, 1$.

3. Preliminaries

In this section, we first study a special oscillatory integral which occurs in later sections. The results are standard, but we include a proof for completeness and the convenience of the readers.

Let $\rho \in C_0^\infty(\mathbb{R})$ be a real-valued function with $\text{supp } \rho \subset \left[1/2, 2\right]$, $\xi, \eta \in \mathbb{R}$, $\eta \neq 0$, $A > 1$ a constant, and

$$I(\lambda, \epsilon, \xi, \eta) = 1_{[-A, A]}(\xi/\eta) \int_0^\infty \rho(t)e^{i\lambda \phi_\epsilon(t, \xi, \eta)} dt, \quad \lambda > 1,$$

where

$$\phi_\epsilon(t, \xi, \eta) = Q_\epsilon(t) + (\xi/\eta) t.$$

Lemma 3.1. Assume that $Q_\epsilon \in C^N([1/4, 4])$ ($N \geq 5$) is a real-valued function such that $|D^jQ_\epsilon| \leq C_1$ for $0 \leq j \leq N$ and $|D^2Q_\epsilon| \geq c_1$ for constants $C_1$ and $c_1$. If $\chi \in C_0^\infty(\mathbb{R})$ has its support contained in an interval of length $c_1/12$, then either one of the following two statements holds.

1. We have

$$\chi(-\xi/\eta)I(\lambda, \epsilon, \xi, \eta) = O(\lambda^{-(N-1)}).$$

2. For each pair $(\xi, \eta)$ with $-\xi/\eta \in \text{supp } \chi$, there exists a unique $t = t(\xi, \eta) \in [1/3, 13/6]$ such that $t(\xi, \eta) = (Q'_{\epsilon})^{-1}(-\xi/\eta)$ is $(N - 1)$-times differentiable and satisfies

$$D^1_\xi \phi_\epsilon(t(\xi, \eta), \xi, \eta) = 0$$

and

$$\chi(-\xi/\eta)I(\lambda, \epsilon, \xi, \eta) = C\chi(-\xi/\eta)1_{[-A, A]}(\xi/\eta)\rho(t(\xi, \eta)).$$

with $C$ being an absolute constant.
Furthermore, the implicit constants in (3.1) and (3.3) are independent of \( \lambda, \epsilon, \xi, \) and \( \eta. \)

**Proof.** Due to (2.2), we observe that \( Q'_t \) is monotone on \([1/4, 4]\) and that, for any \( t \in [1/3, 13/6] \) and \( r \in (0, 1/12], \) \( Q'_t \) is a bijection from \( B(t, r) \) to an interval which contains \( B(Q'_t(t), c_1 r). \)

Assume that there exist \( a \in [1/2, 2) \) and \( (\xi_0, \eta_0) \) with \( -\xi_0/\eta_0 \in \text{supp} \chi \) such that \( |D^1_1 \phi_t(a, \xi_0, \eta_0)| < c_1/12, \) otherwise we get (3.1) by integration by parts.

Since \( D^1_1 \phi_t(t, \xi, \eta) = Q'_t(t) + \xi/\eta, \) we have that \( -\xi_0/\eta_0 \in B(Q'_t(a), c_1/12). \) It follows from the observation above that there exists a unique \( a_0 \in [1/4, 4] \) such that \( a_0 \in B(a, 1/12) \) and \( Q'_t(a_0) = -\xi_0/\eta_0. \) Thus \( \text{supp} \chi \subset B(Q'_t(a_0), c_1/12). \) The observation above then implies that, for each pair \((\xi, \eta)\) with \( -\xi/\eta \in \text{supp} \chi, \) there exists a unique \( t(\xi, \eta) \in B(a_0, 1/12) \) such that \( Q'_t(t(\xi, \eta)) = -\xi/\eta, \) which is (3.2).

In particular, \( t(\xi, \eta) = (Q'_t)^{-1}(-\xi/\eta), \) whose differentiability is a consequence of the inverse function theorem.

Note that \( B(t(\xi, \eta), 1/12) \subset [1/4, 9/4] \) and we also have

\[ |D^1_1 \phi_t(t, \xi, \eta)| = |D^1_1 \phi_t(t, \xi, \eta) - D^1_1 \phi_t(t(\xi, \eta), \xi, \eta)| \geq c_1 |t - t(\xi, \eta)|. \]

Applying to \( I(\lambda, \epsilon, \xi, \eta) \) the method of stationary phase on \( B(t(\xi, \eta), 1/12) \) and integration by parts outside \( B(t(\xi, \eta), 1/24) \) yields (3.3). \( \square \)

**Remark 3.2.** A similar argument in high dimensions can be found in the proof of [11 Proposition 2.4]. For the method of stationary phase, the reader can check [6 Section 7.7].

We quote below Li’s [11 Theorem 6.2] with a small modification in the statement for the sake of our later application, however its proof remains the same. Let \( \sigma \in (0, 1], I \subset \mathbb{R} \) be a fixed bounded interval, and \( U(I) \) a nontrivial subset of \( L^2(I) \) such that the \( L^2 \)-norm of every element of \( U(I) \) is uniformly bounded by a constant.

We say that a function \( f \in L^2(I) \) is \( \sigma \)-uniform in \( U(I) \) if

\[ \left| \int_I f(x) u(x) \, dx \right| \leq \sigma \| f \|_{L^2(I)} \quad \text{for all} \ u \in U(I). \]

**Lemma 3.3.** Let \( \mathcal{L} \) be a bounded sublinear functional from \( L^2(I) \) to \( \mathbb{C} \), \( S_\sigma \) the set of all functions that are \( \sigma \)-uniform in \( U(I), \)

\[ A_\sigma = \sup \{ |\mathcal{L}(f)| / \| f \|_{L^2(I)} : f \in S_\sigma, f \neq 0 \}, \]

and

\[ M = \sup_{u \in U(I)} |\mathcal{L}(u)|. \]

Then

\[ \| \mathcal{L} \| \leq \max \{ A_\sigma, 2\sigma^{-1} M \}. \]

\( ^3 \)\( B(t, r) \) denotes the interval \( (t - r, t + r). \)
We also need the following theorem to handle the minor part in Section 6. This theorem is a variant of the results in [10] Theorem 2.1 concerning estimates for certain paraproducts. The only change is that the standard dyadic sequence \( \{2^{\alpha_j}\}_{j \in \mathbb{Z}} \) with \( \alpha \in \mathbb{N}\setminus\{0\} \) (in [10]) is replaced by a dyadic-like sequence \( \{\Delta_j\} \) here, while the proof remains the same; see [10] Section 3 and 4.

**Theorem 3.4.** Let \( L \in \mathbb{Z} \) and let \( \{\Delta_j\}_{j>L} \) be a sequence of positive numbers which is dyadic-like, i.e. there is a \( K \in \mathbb{Z} \) s.t. for all \( j > L \) and \( j+K > L \) the following holds

\[
\Delta_{j+K} \geq 2\Delta_j,
\]

(3.4)

Let \( \Phi_1 \) be a Schwartz function on \( \mathbb{R} \) whose Fourier transform is a standard bump function supported on \( [-2,-1/2] \cup [1/2,2] \), and \( \Phi_2 \) be a Schwartz function on \( \mathbb{R} \) such that \( \Phi_2 \) is a standard bump function supported on \( [-1,1] \) and \( \Phi_2(0) = 1 \). For \((n_1,n_2) \in \mathbb{Z}^2 \) and \( l = 1 \) or \( 2 \), set

\[
\mathcal{M}_{l,n_1,n_2}(\xi,\eta) = \sum_{j>L} \hat{\Phi}_1(\frac{\xi}{2^j}) e^{2\pi i n_1 \frac{\xi}{2^j}} \hat{\Phi}_2(\frac{\eta}{2^j}) e^{2\pi i n_2 \frac{\eta}{2^j}}.
\]

Then for \( l = 1 \) and \( 2 \), for any \( p_1, p_2 > 1 \), with \( 1/r = 1/p_1 + 1/p_2 \), there is a constant \( C \) independent of \((n_1,n_2)\) such that for all \( f_1 \in L^{p_1}(\mathbb{R}) \), \( f_2 \in L^{p_2}(\mathbb{R}) \), the following holds

\[
\|\Pi_{l,n_1,n_2}(f_1,f_2)\|_r \leq C(1 + n_1^2)^{10}(1 + n_2^2)^{10}\|f_1\|_{p_1}\|f_2\|_{p_2},
\]

where

\[
\Pi_{l,n_1,n_2}(f_1,f_2)(x) = \iint \mathcal{M}_{l,n_1,n_2}(\xi,\eta) \hat{f}_1(\xi) \hat{f}_2(\eta) e^{2\pi i (\xi+\eta)x} \, d\xi \, d\eta.
\]

4. The main estimates

Let \( \tilde{\varphi} \in C_0^\infty(\mathbb{R}) \) such that \( \tilde{\varphi} = 1 \) on \( \{t \in \mathbb{R} : 3/8 \leq |t| \leq 17/8 \} \) and \( \text{supp} \, \tilde{\varphi} \subset \{t \in \mathbb{R} : 1/4 \leq |t| \leq 9/4 \} \). For \( j, m \in \mathbb{N} \) denote \( \epsilon_j = 2^{-j} \) and

\[
K_{j,m}(\xi,\eta) = \int_0^\infty \rho(t) e^{-2\pi i 2^m \eta \phi_j(t,\xi,\eta)} \, dt,
\]

where \( \rho \) and \( \phi_j \) are as defined at the beginning of Section 3.

For \( f, g \in L^2(\mathbb{R}) \) denote, when \( |\gamma'(\epsilon_j)| \leq K_1|\epsilon_j|^{-c_1} \),

\[
B_{j,m}^\varphi(f,g)(x) = |\gamma'(\epsilon_j)|^{-1/2} \iint \hat{f}(\xi) \tilde{\varphi}(\xi) \hat{g}(\eta) \tilde{\varphi}(\eta) e^{2\pi i (\gamma'(\epsilon_j)\xi + \eta)x} K_{j,m}(\xi,\eta) \, d\xi \, d\eta,
\]

and, when \( |\gamma'(\epsilon_j)| \geq K_2|\epsilon_j|^{-c_1} \),

\[
B_{j,m}^\varphi(f,g)(x) = |\gamma'(\epsilon_j)|^{-1/2} \iint \hat{f}(\xi) \tilde{\varphi}(\xi) \hat{g}(\eta) \tilde{\varphi}(\eta) e^{2\pi i (\xi + (\gamma'(\epsilon_j))^{-1}\eta)x} K_{j,m}(\xi,\eta) \, d\xi \, d\eta.
\]
Proposition 4.1. Assume that $\Gamma(t) = (t, \gamma(t)) \in F(1,1)$. For any $\beta < 1$, there exist an $L \in \mathbb{N}$ and a constant $C_\beta$ such that whenever $j \geq L$, $m \in \mathbb{N}$, $n \in \mathbb{Z}$, and $f, g \in L^2(\mathbb{R})$, we have

1. if $|\gamma'(\epsilon_j)| \leq K_1|\epsilon_j|^{c_1}$, then
   \[
   \|B^\sigma_{j,m}(f,g)\|_{1} \leq C_\beta C_{j,m} \|f\|_2 \|g\|_2,
   \]
   where
   \[
   C_{j,m} = \begin{cases} 2^{-m/16} & \text{if } |\gamma'(\epsilon_j)| > 2^{-m}, \\ 2^{-\beta m/4} & \text{if } |\gamma'(\epsilon_j)| \leq 2^{-m}; \end{cases}
   \]

2. if $|\gamma'(\epsilon_j)| \geq K_2|\epsilon_j|^{-c_1}$, then
   \[
   \|B^\sigma_{j,m}(f,g)\|_{1} \leq C_\beta C'_{j,m} \|f\|_2 \|g\|_2;
   \]
   where
   \[
   C'_{j,m} = \begin{cases} 2^{-m/16} & \text{if } |\gamma'(\epsilon_j)| < 2^{m}, \\ 2^{-\beta m/4} & \text{if } |\gamma'(\epsilon_j)| \geq 2^{m}. \end{cases}
   \]

The rest of this section is devoted to the proof of Proposition 4.1.

We first observe that there is actually a symmetry between the case $|\gamma'(\epsilon_j)| \leq K_1|\epsilon_j|^{c_1}$ and the case $|\gamma'(\epsilon_j)| \geq K_2|\epsilon_j|^{-c_1}$, hence we will only prove the former case while the other one can be handled similarly. We can also simplify the domain of integration of $B^\sigma_{j,m}(f,g)(x)$ by using a decomposition $\hat{\varphi} = \hat{\varphi}1_{(0,\infty)} + \hat{\varphi}1_{(-\infty,0)}$, which allows us to restrict the domain to one of the cubes $(\pm[1/4,9/4]) \times (\pm[1/4,9/4])$. We will still use $\hat{\varphi}$ below but with its support contained in either $[1/4,9/4]$ or $[-9/4,-1/4]$ (and this won’t cause any problem).

The proof is split into three parts. In the first part, we apply the $TT^*$ method to estimate $\|B^\sigma_{j,m}(f,g)\|_1$, during which procedure we need a standard result from the oscillatory integral theory and a necessary condition $|\gamma'(\epsilon_j)| > 2^{-m}$. The bound we get (see (1.1) below) is efficient when $|\gamma'(\epsilon_j)|$ is large but inefficient when $|\gamma'(\epsilon_j)|$ is close to $2^{-m}$. In the second part, with the help of Lemma 3.3 (the method of $\sigma$-uniformity introduced in Li [11]), we can put certain restrictions on the function $f$ (or $g$) and reduce the estimate of $\|B^\sigma_{j,m}(f,g)\|_1$ to a restricted version, to which the $TT^*$ method can be applied without extra assumptions on the size of $|\gamma'(\epsilon_j)|$.

The bound we get in this part (see (1.2) and (1.3) below) is efficient when $|\gamma'(\epsilon_j)|$ is small (even when $|\gamma'(\epsilon_j)|$ is close to $2^{-m}$) but inefficient when $|\gamma'(\epsilon_j)|$ is large (see also Li [11], P. 18). In the last part, we take advantage of both results and prove the desired estimate.

4.1. Part 1: $j \geq L$, $m \in \mathbb{N}$ such that $|\gamma'(\epsilon_j)| > 2^{-m}$. We first prove that, for $h \in L^2(\mathbb{R})$,

\[
\left| \int B^\sigma_{j,m}(f,g)(x)h(x) \, dx \right| \leq C(2^m|\gamma'(\epsilon_j)|)^{-1/6} \|f\|_2 \|g\|_2 \cdot (2^{-m}|\gamma'(\epsilon_j)|)^{1/2} \|h\|_2,
\]

where $C(2^m|\gamma'(\epsilon_j)|)^{-1/6} \leq 2^{-m/8}$.
which trivially leads to the estimate
\begin{equation}
\|B_{j,m}^\varepsilon(f,g)\|_2 \leq C(2^m|\gamma'(\varepsilon_j)|)^{-1/6}\|f\|_2\|g\|_2.
\end{equation}

We can find a finite open cover of the interval $[-10,10]$ by using open intervals of length $c_1/12$, associated to which we can construct a partition of unity. By inserting this partition of unity we reduce the estimate of $\int B_{j,m}^\varepsilon(f,g)(x)h(x)\,dx$ to
\[\int \tilde{B}_{j,m}^\varepsilon(f,g)(x)h(x)\,dx = |\gamma'(\varepsilon_j)|^{1/2} \int \tilde{f}(\xi)\tilde{g}(\eta)\mathcal{F}^{-1}[h](\gamma'(\varepsilon_j)\xi + \eta)\chi(-\xi/\eta)K_{j,m}(\xi,\eta)\,d\xi\,d\eta,
\]
where $\chi$ is smooth and supported in an interval of length $c_1/12$.

We can then apply Lemma 3.3 to $\chi(-\xi/\eta)K_{j,m}(\xi,\eta)$. If (3.3) holds, then an application of Hölder’s inequality yields
\begin{equation}
\left|\int \tilde{B}_{j,m}^\varepsilon(f,g)(x)h(x)\,dx\right| \leq C2^{-m/2}\|f\|_2\|g\|_2 \cdot (2^{-m}|\gamma'(\varepsilon_j)|)^{1/2}\|h\|_2.
\end{equation}
This estimate immediately leads to (4.3).

Below we will assume that the second statement in Lemma 3.1 holds. Applying (3.3) yields
\begin{equation}
\int \tilde{B}_{j,m}^\varepsilon(f,g)(x)h(x)\,dx = C(2^{-m}|\gamma'(\varepsilon_j)|)^{1/2}.
\end{equation}
\begin{equation}
\int \tilde{f}(\xi)\tilde{g}(\eta)\mathcal{F}^{-1}[h](\gamma'(\varepsilon_j)\xi + \eta)a(\xi,\eta)e^{-2\pi i 2^m\eta\phi_j(t(\xi,\eta),\xi,\eta)}\,d\xi\,d\eta,
\end{equation}
where we have omitted the error term in (3.3) (since it leads to the same bound as in (4.3)), and $a(\xi,\eta)$ is defined as
\[a(\xi,\eta) = \chi(-\xi/\eta)\rho(t(\xi,\eta))|\eta|^{-1/2}|\mathcal{D}^2\phi_j(t(\xi,\eta),\xi,\eta)|^{-1/2}.
\]
Applying to the double integral in (4.6) a change of variables $\gamma'(\varepsilon_j)\xi + \eta \rightarrow \xi, \eta/\gamma'(\varepsilon_j) \rightarrow \eta$ and then Hölder’s inequality yields
\begin{equation}
\left|\int \tilde{B}_{j,m}^\varepsilon(f,g)(x)h(x)\,dx\right| \leq C\|T_{j,m}(f,g)\|_2 \cdot (2^{-m}|\gamma'(\varepsilon_j)|)^{1/2}\|h\|_2,
\end{equation}
where
\[T_{j,m}(f,g)(\xi) = \int \tilde{f}(\xi)\tilde{g}(\eta)\mathcal{F}^{-1}[h]\gamma'(\varepsilon_j)\eta)a(\gamma'(\varepsilon_j)^{-1}\xi - \eta, \gamma'(\varepsilon_j)\eta)\cdot e^{-2\pi i 2^m(\gamma'(\varepsilon_j)\eta)\phi_j(t(\gamma'(\varepsilon_j)^{-1}\xi - \eta, \gamma'(\varepsilon_j)\eta),\gamma'(\varepsilon_j)^{-1}\xi - \eta, \gamma'(\varepsilon_j)\eta)\,d\eta}.
\]
We then have, after a change of variables,
\begin{equation}
\|T_{j,m}(f,g)\|_2^2 = \int T_{j,m}(f,g)(\xi)\overline{T_{j,m}(f,g)(\xi)}\,d\xi = \int d\tau \int F_\tau(x)G_\tau(y)A_\tau(x,y)e^{-2\pi i 2^mP_\tau(x,y)}\,dx\,dy,
\end{equation}
where
\[
F_\tau(x) = \hat{f}(x - \tau) \overline{\hat{f}(x)},
\]
\[
G_\tau(y) = \hat{g}(y + \gamma'(\epsilon_j) \tau) \overline{\hat{g}(y)},
\]
\[
A_\tau(x, y) = a(x - \tau, y + \gamma'(\epsilon_j) \tau) \overline{a(x, y)},
\]
and
\[
P_\tau(x, y) = P_1(x - \tau, y + \gamma'(\epsilon_j) \tau) - P_1(x, y)
\]
with
\[
P_1(x, y) = y_\phi(t(x, y), x, y).
\]

In order to estimate the inner double integral in (4.8), we first show that there exists an \(L \in \mathbb{N}\) such that if \(j \geq L\) then
\[
|\frac{\partial^2 P_\tau}{\partial y \partial x}(x, y)| \sim |\tau|.
\]

Recall that \(t(x, y)\) satisfies (3.2) (with \(\xi, \eta, \) and \(\epsilon\) replaced by \(x, y, \) and \(\epsilon_j\) respectively). By implicit differentiation, we get
\[
\frac{\partial t}{\partial x}(x, y) = -\frac{1}{y Q''_{\epsilon_j}(t(x, y))} \quad \text{and} \quad \frac{\partial t}{\partial y}(x, y) = -\frac{Q'_{\epsilon_j}(t(x, y))}{y Q''_{\epsilon_j}(t(x, y))}.
\]

By (2.1), (2.2), and (2.3), we then have
\[
\frac{\partial^2 t}{\partial x \partial y}(x, y) = \frac{1}{y^2} \frac{(Q''_{\epsilon_j})^2 - Q'_{\epsilon_j} Q'''_{\epsilon_j}(t(x, y))}{(Q''_{\epsilon_j})^3} \approx 1
\]
and
\[
\frac{\partial^2 t}{\partial y^2}(x, y) = \frac{1}{y^2} \frac{Q'_{\epsilon_j}(2(Q''_{\epsilon_j})^2 - Q'_{\epsilon_j} Q'''_{\epsilon_j}(t(x, y)))}{(Q''_{\epsilon_j})^3} \lesssim 1.
\]

By using (3.2) we also get
\[
\frac{\partial^2 P_1}{\partial y \partial x}(x, y) = \frac{\partial t}{\partial y}(x, y).
\]

Noticing that \(|\gamma'(\epsilon_j)|\) is small if \(L\) is large, by the mean value theorem we get (4.9). Let \(\tau_0 = (2^m |\gamma'(\epsilon_j)|)^{-1/3}\). We have the following splitting of (4.8):
\[
\|T_{j, m}(f, g)\|_2^2 = \left( \int_{|\tau| < \tau_0} + \int_{\tau_0 \leq |\tau| \leq 10} \right) \cdot \iint F_\tau(x) G_\tau(y) A_\tau(x, y) e^{-2\pi i \sigma_{2m} P_\tau(x, y)} \, dx \, dy.
\]
where \( g \) leads to, for \( B (4.10) \)

\[
\|T_{j,m}(f,g)\|_2^2 \leq C_{\alpha}(\|f\|_2^2 + C \int_{\tau_0 \leq |\tau| \leq 10} (2^m |\tau|)^{-1/2} \|F_\tau\|_2 \|G_\tau\|_2 \, d\tau)
\leq C(\tau_0 + (2^m |\gamma'(\epsilon_j)|\tau_0)^{-1/2}) \|f\|_2^2 \|g\|_2^2
\leq C(2^m |\gamma'(\epsilon_j))|^{-1/3} \|f\|_2^2 \|g\|_2^2.
\]

To conclude, the desired estimate (4.13) follows from (4.5), (4.7), and the estimate above of \( \|T_{j,m}(f,g)\|_2 \).

4.2. Part 2: \( j \geq L, m \in \mathbb{N} \). We can find a finite open cover of the interval \([-36C_1, 36C_1]\) by using open intervals of length \( C_1/24 \), associated to which we can construct a partition of unity \( \{\chi_s : 1 \leq s \leq \Theta\} \) such that \( \sum_s \chi_s = 1 \) in \([-36C_1, 36C_1]\) and each \( \chi_s \) is smooth and supported in an interval that belongs to the finite open cover above.

Lemma 3.1 will be applied to \( \chi_s(-\xi/\eta)K_{j,m}(\xi,\eta) \) (below). Here we denote \( S \) to be the collection of all \( 1 \leq s \leq \Theta \) for which the second statement in Lemma 3.1 holds. Let \( I \) be either \([1/4, 9/4]\) or \([-9/4, -1/4]\), and

\[
U(I) := \{u_{s,r,\eta}(\xi) \in L^2(I) : s \in S, r \in \mathbb{R}, 1/16C_1 \leq |\eta| \leq 9C_1\},
\]

where

\[
u_{s,r,\eta}(\xi) = \chi_s(-\xi/\eta)e^{2\pi i(2m\eta \phi_{s,\eta}(t(\xi,\eta),\xi,\eta)+r\xi)}.
\]

According to Lemma 3.1 we will finish this part in three steps.

Step 1: Let \( \int_I \), the restriction of \( \hat{f} \) to \( I \), be an arbitrary function in \( L^2(I) \) that is \( \sigma \)-uniform in \( U(I) \).

We first note that \( B_{j,m}^\varphi(f,g)(x) \) in the time space can be expressed as

\[
(4.10) \quad B_{j,m}^\varphi(f,g)(x) = |\gamma'(\epsilon_j)|^{1/2} \int_0^\infty f * \varphi(\gamma'(\epsilon_j)x - 2^m t)g * \varphi(x - 2^m Q_{\epsilon_j}(t))\rho(t) \, dt,
\]

which leads to, for \( h \in L^2(\mathbb{R}) \),

\[
\int B_{j,m}^\varphi(f,g)(x)h(x) \, dx = |\gamma'(\epsilon_j)|^{1/2}.
\]

\[
\sum_{l \in \mathbb{Z}} \iint_0^\infty f * \varphi(\gamma'(\epsilon_j)x - 2^m t)g_{j,m,l}(x - 2^m Q_{\epsilon_j}(t))\rho(t)(1_{\gamma'(\epsilon_j)\leq l = \gamma'(\epsilon_j)} - 1)h(x) \, dt \, dx,
\]

where \( g_{j,m,l} = 1_{j,m,l} * g \ast \varphi \) with \( I_{j,m,l} = [\alpha_{j,l}m - C_1 2^m, \alpha_{j,l+1} + C_1 2^m] \) and \( \alpha_{j,l} = |\gamma'(\epsilon_j)|^{-1} \). In the frequency space we then have

\[
\int B_{j,m}^\varphi(f,g)(x)h(x) \, dx = |\gamma'(\epsilon_j)|^{1/2}.
\]

\[
\sum_{l \in \mathbb{Z}} \iint \hat{f}\hat{\varphi}(\xi)e^{2\pi i \gamma'(\epsilon_j)\xi g_{j,m,l}(\eta)}e^{2\pi i \eta x} K_{j,m}(\xi,\eta)(1_{\gamma'(\epsilon_j)\leq l = \gamma'(\epsilon_j)} - 1)h(x) \, dx \, d\xi \, d\eta.
\]
Let \( \tilde{\varphi}_1 \in C_0^\infty(\mathbb{R}) \) such that \( \tilde{\varphi}_1(\eta) = 1 \) if \( |\eta| \in [1/8C_1, 9C_1/2] \) and \( \text{supp} \tilde{\varphi}_1 \subset \{ x \in \mathbb{R} : 1/16C_1 \leq |x| \leq 9C_1 \} \). By using 1 = \( \tilde{\varphi}_1(\eta) + (1 - \tilde{\varphi}_1(\eta)) \) and the power series of \( e^{2\pi i \gamma'/(\xi - \alpha_{j,l})} \), we get

\[
\int B_{j,m}^\rho(f, g)(x)h(x) \, dx = I + II,
\]

where

\[
I = |\gamma'(\epsilon_j)|^{1/2} \sum_{l \in \mathbb{Z}} \sum_{p=0}^{\infty} \frac{(2\pi i)^p}{p!} \int \tilde{f}(\xi)\xi^p e^{2\pi i \gamma'/\alpha_{j,l}} \tilde{\varphi}_1(\eta).
\]

\[
g_{j,m,l}(\eta) \tilde{\varphi}_1(\eta) K_{j,m}(\xi, \eta) F^{-1}[\gamma'((\cdot - \alpha_{j,l}))^p (1_{\gamma'(\epsilon_j)} - 1, h)(\cdot)](\eta) \, d\xi \, d\eta
\]

and

\[
II = |\gamma'(\epsilon_j)|^{1/2} \sum_{l \in \mathbb{Z}} \sum_{p=0}^{\infty} \frac{(2\pi i)^p}{p!} \int \tilde{f}(\xi)\xi^p e^{2\pi i \gamma'/\alpha_{j,l}} \tilde{\varphi}_1(\eta).
\]

\[
g_{j,m,l}(\eta)(1 - \tilde{\varphi}_1(\eta)) K_{j,m}(\xi, \eta) F^{-1}[\gamma'((\cdot - \alpha_{j,l}))^p (1_{\gamma'(\epsilon_j)} - 1, h)(\cdot)](\eta) \, d\xi \, d\eta.
\]

We first estimate Sum II. When \( 1 - \tilde{\varphi}_1(\eta) \neq 0 \), Remark 2.4 (2) implies that the gradient of the phase function of \( K_{j,m}(\xi, \eta) \) has a uniform lower bound, which leads to the bound \( K_{j,m}(\xi, \eta) = O(2^{-m}) \). Then by Hölder’s inequality we get

\[
|II| \leq C2^{-m}|\gamma'(\epsilon_j)|^{1/2} \sum_{l \in \mathbb{Z}} \|g_{j,m,l}\|_2 \|1_{\gamma'(\epsilon_j)} - 1, h\|_2.
\]

Applying the Cauchy-Schwarz inequality yields

\[(4.11)\]

\[
|II| \leq \begin{cases} 
C2^{-m/2} \|1_{\tilde{f}}\|_2 \|g\|_2 \cdot (2^{-m}|\gamma'(\epsilon_j)|^{1/2}\|h\|_2, & \text{if } |\gamma'(\epsilon_j)| \leq 2^{-m}, \\
C|\gamma'(\epsilon_j)|^{1/2} \|1_{\tilde{f}}\|_2 \|g\|_2 \cdot (2^{-m}|\gamma'(\epsilon_j)|^{1/2}\|h\|_2, & \text{if } |\gamma'(\epsilon_j)| > 2^{-m}.
\end{cases}
\]

The estimate of Sum I, by using the partition of unity we have constructed at the beginning of this subsection, can be reduced to

\[
I_s = |\gamma'(\epsilon_j)|^{1/2} \sum_{l \in \mathbb{Z}} \sum_{p=0}^{\infty} \frac{(2\pi i)^p}{p!} \int \tilde{f}(\xi)\xi^p e^{2\pi i \gamma'/\alpha_{j,l}} g_{j,m,l}(\eta) \tilde{\varphi}_1(\eta).
\]

\[
\chi_s(-\xi/\eta) K_{j,m}(\xi, \eta) F^{-1}[\gamma'((\cdot - \alpha_{j,l}))^p (1_{\gamma'(\epsilon_j)} - 1, h)(\cdot)](\eta) \, d\xi \, d\eta
\]

for any \( 1 \leq s \leq \Theta \). We apply Lemma 3.1 to \( \chi_s(-\xi/\eta) K_{j,m}(\xi, \eta) \). If (3.1) holds, then \( I_s \) is bounded by (4.11) too. Hence we may assume that the second statement in Lemma 3.1 holds. Applying (3.3) yields

\[
I_s = C(2^{-m}|\gamma'(\epsilon_j)|^{1/2} \sum_{l \in \mathbb{Z}} \sum_{p=0}^{\infty} \frac{(2\pi i)^p}{p!} \int \Re(\eta) g_{j,m,l}(\eta) F^{-1}[\gamma'((\cdot - \alpha_{j,l}))^p (1_{\gamma'(\epsilon_j)} - 1, h)(\cdot)](\eta) \, d\eta,
\]

\[
\int \Re(\eta) g_{j,m,l}(\eta) F^{-1}[\gamma'((\cdot - \alpha_{j,l}))^p (1_{\gamma'(\epsilon_j)} - 1, h)(\cdot)](\eta) \, d\eta.
\]
where we have omitted the error term in (3.3) (since it leads to the same bound as in (4.11)), and \( \mathfrak{M}(\eta) \) is defined as
\[
\mathfrak{M}(\eta) := \int_I b(\xi, \eta) \hat{f}(\xi) \chi_s(-\xi/\eta)e^{-2\pi i (2^m \eta \phi_{\xi_j}(t(\xi, \eta), \xi, \eta) - \gamma'(\xi_j)\alpha_j, \xi) \frac{\xi}{\eta}} \, d\xi
\]
with
\[
b(\xi, \eta) = \hat{\varphi}(\xi) \hat{\varphi}_1(\eta) \xi^\rho(t(\xi, \eta)) |\eta|^{-1/2} |D_\xi^2 \phi_{\xi_j}(t(\xi, \eta), \xi, \eta)|^{-1/2}.
\]
Using the Fourier series of \( b(\xi, \eta) \) and the assumption that \( \hat{f}\mathbf{1} \) is \( \sigma \)-uniform in \( U(\mathbf{1}) \), we have
\[
|\mathfrak{M}(\eta)| \leq C \sigma \|1_\mathbf{1} \hat{f}\|_2.
\]
Hence by using Hölder’s and the Cauchy-Schwarz inequalities we get
\[
|I_s| \leq \begin{cases} 
C\sigma \|1_\mathbf{1} \hat{f}\|_2 \|g\|_2 \|h\|_2, & \text{if } |\gamma'(\xi_j)| \leq 2^{-m}, \\
C(2^m |\gamma'(\xi_j)|)^{1/2} \|1_\mathbf{1} \hat{f}\|_2 \|g\|_2 \|h\|_2, & \text{if } |\gamma'(\xi_j)| > 2^{-m}.
\end{cases}
\]
To conclude Step 1, if \( \sigma > 2^{-m/2} \), then the bound above of \( I_s \) and (4.11) lead to, for \( h \in L^\infty(\mathbb{R}) \),
\[
\left| \int B_{j,m}^\varphi(f, g)(x) 1_{2^{-m}\gamma'(\xi_j)^{-1}, n}(x) h(x) \, dx \right|
\leq \begin{cases} 
C\sigma \|1_\mathbf{1} \hat{f}\|_2 \|g\|_2 \|h\|_\infty, & \text{if } |\gamma'(\xi_j)| \leq 2^{-m}, \\
C(2^m |\gamma'(\xi_j)|)^{1/2} \|1_\mathbf{1} \hat{f}\|_2 \|g\|_2 \|h\|_\infty, & \text{if } |\gamma'(\xi_j)| > 2^{-m}.
\end{cases}
\]

**Step 2:** We now assume that \( \hat{f}\mathbf{1} \in U(\mathbf{1}) \).

By using (4.10), a change of variables \( x \to 2^m \gamma'(\xi_j)^{-1}(x + \gamma'(\xi_j)Q_{\xi_j}(t)) \), and Hölder’s inequality, we have, for \( h \in L^\infty(\mathbb{R}) \),
\[
\left| \int B_{j,m}^\varphi(f, g)(x) h(x) \, dx \right| = 2^m |\gamma'(\xi_j)|^{-1/2} \left| \int_0^\infty f * \varphi(2^m(x + \gamma'(\xi_j)Q_{\xi_j}(t) - t)) g * \varphi(2^m \gamma'(\xi_j)^{-1}x) h_{j,m}(x + \gamma'(\xi_j)Q_{\xi_j}(t)) \rho(t) \, dt \, dx \right|
\]
\[
\leq C \|g\|_2 \|T_1(h)\|_2,
\]
where \( h_{j,m}(x) = h(2^m \gamma'(\xi_j)^{-1}x) \) and \( T_1(h)(x) = 2^{m/2} \int_0^\infty f * \varphi(2^m(x + \gamma'(\xi_j)Q_{\xi_j}(t) - t)) h_{j,m}(x + \gamma'(\xi_j)Q_{\xi_j}(t)) \rho(t) \, dt. \)

Let \( \hat{f}\mathbf{1} = u_{s,r,\eta}(\xi) \) for arbitrarily fixed \( s \in S, r \in \mathbb{R}, \) and \( 1/16C_1 \leq |\eta| \leq 9C_1. \) By applying the Fourier inversion formula to \( f * \varphi \) and changing variables, we get
\[
\|T_1(h)\|_2^2 = 2^m \int \int_0^\infty K_1(x, t) h_{j,m}(x - 2^{-m}r + \gamma'(\xi_j)Q_{\xi_j}(t)) \rho(t) \, dt \, dx,
\]
where
\[
K_1(x, t) = \int \varphi(\xi) \chi_s(-\xi/\eta)e^{2\pi i 2^m \eta [\phi_{\xi_j}(t(\xi, \eta), \xi, \eta) + y(x, t)(\xi/\eta)]} \, d\xi
\]
with
\[ y = y(x, t) = x + \gamma'(\epsilon_j)Q_{\epsilon_j}(t) - t. \]

Let \( \chi_M \) be a smooth cut-off function supported in \([-M, M]\), which equals 1 in \([-M/2, M/2]\). We decompose the right hand side of \((4.14)\) into two parts by using the decomposition 1 = (1 − \( \chi_M(x) \)) + \( \chi_M(x) \) to restrict the integration domain of \( x \) to \( \{ x \in \mathbb{R} : |x| \geq M/2 \} \) and \( \{ x \in \mathbb{R} : |x| < M \} \) respectively for a sufficiently large constant \( M \). The former part is bounded by
\[
C 2^{-m} \| h \|_\infty^2,
\]
since integration by parts yields \( K_1(x, t) = O(2^{-m}|x|^{-1}) \).

We next consider the latter part with \( |x| < M \). After inserting a partition of unity, we may replace \( K_1(x, t) \) by \( \tilde{\chi}(-y(x, t))K_1(x, t) \) with a smooth cut-off function \( \tilde{\chi} \) supported in an interval of sufficiently small length. Then by repeating the argument in the proof of Lemma 3.1, we have that either \( \tilde{\chi}(-y(x, t))K_1(x, t) = O(2^{-m}) \) (leading to the bound \((4.10)\)) or the phase function in \((4.16)\) has a critical point \( \xi(x, t) \) satisfying
\[
t(\xi(x, t), \eta) = -y(x, t).
\]
This equation, together with \( \partial_\xi \phi_{\epsilon_j}(t(\xi, \eta), \xi, \eta) = 0 \) (namely, the equation \((3.2)\) satisfied by \( t(\xi, \eta) \)), yields
\[
\xi(x, t) = -\eta Q_{\epsilon_j}'(-y(x, t)).
\]
By using the method of stationary phase in a neighborhood of \( \xi(x, t) \) and integration by parts away from it, we get the following asymptotic formula.
\[
\tilde{\chi}(-y(x, t))K_1(x, t) = C\tilde{\chi}(-y(x, t))\chi_s(-\xi(x, t)/\eta)\tilde{\rho}(\xi(x, t))|\partial_\xi t(\xi(x, t), \eta)|^{-1/2}.
\]
By using the leading term above and a change of variables \( u = Q_{\epsilon_j}(t) \), we now need to estimate
\[
\int \chi_M(x) \left| \int h_{j,m}(x - 2^{-m}r + \gamma'(\epsilon_j)u)k(x, u)e^{2\pi i 2^m\eta Q_{\epsilon_j}'(-y(x, Q_{\epsilon_j}^{-1}(u)))} du \right|^2 dx,
\]
where
\[
k(x, u) = \tilde{\chi}(-y(x, Q_{\epsilon_j}^{-1}(u)))\chi_s(-\xi(x, Q_{\epsilon_j}^{-1}(u))/\eta)\tilde{\rho}(\xi(x, Q_{\epsilon_j}^{-1}(u))).
\]
By changing variables \( u_1 = v + \tau, u_2 = v \), followed by \( x \to x - \gamma'(\epsilon_j)v \), \((4.17)\) becomes
\[
\int d\tau \int H_\tau(x) dx \int K_{\tau,\tau}(v)e^{2\pi i 2^m\eta P_{\tau,\tau}(v)} dv,
\]
where all three integrals are over some finite intervals,
\[
H_\tau(x) = h_{j,m}(x - 2^{-m}r + \gamma'(\epsilon_j)\tau)h_{j,m}(x - 2^{-m}r),
\]
\[ K_{\tau,x}(v) = \chi_M(x - \gamma'(\epsilon_j)v)k(x - \gamma'(\epsilon_j)v, v + \tau)k(x - \gamma'(\epsilon_j)v, v), \]
and
\[ P_{\tau,x}(v) = P_2(x + \gamma'(\epsilon_j)\tau, v + \tau) - P_2(x, v) \]
with
\[ P_2(x, v) = Q_{\epsilon_j}(-|x - Q_{\epsilon_j}^{-1}(v)|). \]

Before applying integration by parts to the innermost integral in (4.18) we first estimate its phase function \( P_{\tau,x}(v) \). Actually we have that if \(|\gamma'(\epsilon_j)|/|x|\) is sufficiently small then
\[ |D_\tau P_{\tau,x}(v)| \approx |x| |\tau| \]
and
\[ |D^2_{\tau} P_{\tau,x}(v)| \lesssim |x| |\tau|. \]
The (4.19) follows from the mean value theorem and the following estimates
\[ \frac{\partial^2 P_2}{\partial x \partial v}(x, v) = -\frac{Q''_{\epsilon_j}(-|x - Q_{\epsilon_j}^{-1}(v)|)}{Q'_{\epsilon_j}(Q_{\epsilon_j}^{-1}(v))} \approx 1 \]
and
\[ \frac{\partial^2 P_2}{\partial v^2}(x, v) = x \cdot \frac{Q''_{\epsilon_j}(-|x - Q_{\epsilon_j}^{-1}(v)|)}{(Q'_{\epsilon_j}(Q_{\epsilon_j}^{-1}(v)))^2} \cdot \frac{(Q'_{\epsilon_j})^2 - Q''_{\epsilon_j}Q''_{\epsilon_j}(c) \approx |x|,} \]
where \( c \) is between \(-|x - Q_{\epsilon_j}^{-1}(v)|\) and \( Q_{\epsilon_j}^{-1}(v) \). The (4.20) can be proved similarly.

Therefore, if \(|\gamma'(\epsilon_j)|/|x|\) is sufficiently small, for any \( \beta < 1 \) we have
\[ \left| \int K_{\tau,x}(v)e^{2\pi im \eta P_{\tau,x}(v)} dv \right| \leq C \min \{1, (2^m |x| |\tau|)^{-1} \} \leq C(2^m |x| |\tau|)^{-\beta}. \]

We now estimate (4.18) by splitting it into two parts (depending on the size of \(|\gamma'(\epsilon_j)|/|x|\)) and using the trivial estimate and the bound above respectively. Then it is bounded by
\[ C(|\gamma'(\epsilon_j)| + 2^{-\beta m})\|h\|_{L^\infty}. \]

To conclude Step 2, by (4.13), (4.14), (4.16), and (4.21), we get, for \( h \in L^\infty(\mathbb{R}) \),
\[ \left| \int B_{\gamma,j,m}^\varphi(f, g)(x)1_{2^m \gamma'(\epsilon_j) - 1, n}(x)h(x) dx \right| \leq \begin{cases} \frac{C2^{-\beta m/2}\|g\|_2\|h\|_{L^\infty}}{C_{\max\{\gamma'(\epsilon_j)|2^{-\beta m}\}}^{1/2}\|g\|_2\|h\|_{L^\infty}}, & \text{if } |\gamma'(\epsilon_j)| \leq 2^{-m}, \\ C_{\max\{\gamma'(\epsilon_j)|2^{-\beta m}\}}^{1/2}\|g\|_2\|h\|_{L^\infty}, & \text{if } |\gamma'(\epsilon_j)| > 2^{-m}. \end{cases} \]

**Step 3:** To conclude this subsection (namely, Part 2), by using Lemma 3.3 and the estimates (4.12) and (4.22), we get that for any \( \beta < 1 \)
\[ \|B_{\gamma,j,m}^\varphi(f, g)1_{2^m \gamma'(\epsilon_j) - 1, n}\| \leq C2^{-\beta m/4}\|f\|_2\|g\|_2, \quad \text{if } |\gamma'(\epsilon_j)| \leq 2^{-\beta m}, \]
Proposition 5.1. Assume that 
\[ ||\phi||_{L} \]

Proof of Proposition 5.1. published as Li [11].

Remark 5.2. This proposition is a consequence of Proposition 4.1. It is essentially the Lemma 5.1 contained in the arXiv preprint (arXiv:0805.0107) (which was later published as Li [11]).

5. Estimate of \( ||B_{j,m}(f,g)||_1 \)

Let \( \hat{\Phi} \in C_c^\infty(\mathbb{R}) \) be supported in \( \{ \xi \in \mathbb{R} : 1/2 \leq |\xi| \leq 2 \} \) and \( B_{j,m}(f,g) \) be as defined at the beginning of Section 4 (with \( \varphi \) there replaced by \( \hat{\Phi} \)).

**Proposition 5.1.** Assume that \( \Gamma(t) = (t, \gamma(t)) \in F(-1,1) \). For any \( \beta < 1 \), there exist an \( L \in \mathbb{N} \) and a constant \( C_\beta' \) such that whenever \( j \geq L, m \in \mathbb{N}, \) and \( f, g \in L^2(\mathbb{R}) \) we have

\[
||B_{j,m}(f,g)||_1 \leq C_\beta' A_{j,m}^2 ||f||_2 ||g||_2,
\]

where \( A_{1,m} \) equals \( C_{j,m} \) if \( |\gamma'(\epsilon_j)| \leq K_1 |\epsilon_j|^{c_1} \) and \( C'_{j,m} \) if \( |\gamma'(\epsilon_j)| \geq K_2 |\epsilon_j|^{-c_1} \) (with \( C_{j,m} \) and \( C'_{j,m} \) defined as in Proposition 4.4).

**Remark 5.2.** This proposition is a consequence of Proposition 4.1. It is essentially the Lemma 5.1 contained in the arXiv preprint (arXiv:0805.0107) (which was later published as Li [11]).

**Proof of Proposition 5.1.** We only prove the case when \( |\gamma'(\epsilon_j)| \leq K_1 |\epsilon_j|^{c_1} \) while the other case can be handled similarly. Let \( \phi \) be a Schwartz function on \( \mathbb{R} \) such that \( \int \phi = 1 \) and \( \text{supp} \phi \subset [-1/100, 1/100] \). Denote \( \phi_K(x) = K^{-1}\phi(K^{-1}x) \). We have

\[
B_{j,m}(f,g)(x) = |\gamma'(\epsilon_j)|^{1/2} \sum_{n \in \mathbb{Z}} \sum_{k_1, k_2 \in \mathbb{Z}} \int_0^\infty (1_{2^m,n+k_1} * \phi_{2^m}) (x) \Phi(\gamma'(\epsilon_j)x - 2^mt) \cdot (1_{2^m \gamma'(\epsilon_j)-1,n+k_2} * \phi_{2^m \gamma'(\epsilon_j)-1} \cdot g * \Phi)(x - 2^m Q_{\epsilon_j}(t)) \rho(t) dt.
\]

We then make the decomposition \( B_{j,m}(f,g)(x) := I + II \) by splitting the inner summation for \( k_1, k_2 \) into two parts such that the first part, denoted by \( I \), sums over \( \{k_1, k_2 \in \mathbb{Z} :  \max\{|k_1|, |k_2|\} \geq A\} \) and the second one, denoted by \( II \), over \( \{k_1, k_2 \in \mathbb{Z} :  \max\{|k_1|, |k_2|\} < A\} \) with \( A = C_{j,m}^{-1}/2 > 1 \).
Using the fast decay of \(1_{2^m, n+k_1} \ast \phi_{2^m}\) and \(1_{2^m, \gamma'(\epsilon_j)-1, n+k_2} \ast \phi_{2^m, \gamma'(\epsilon_j)-1}\) yields that

\[
|I| \leq C|\gamma'(\epsilon_j)|^{1/2} \sum_{k_1, k_2 \in \mathbb{Z}} \sum_{\max\{|k_1|, |k_2|\} \geq A} \int_0^\infty \frac{|f \ast \Phi(\gamma'(\epsilon_j)x - 2^m t)g \ast \Phi(x - 2^m Q_{\epsilon_j}(t))\rho(t)|}{(1 + |t + k_1|)^{N_1}(1 + |\gamma'(\epsilon_j)Q_{\epsilon_j}(t) + k_2|)^{N_2}} dt \\
\leq C(A^{1-N_1} + A^{1-N_2})|\gamma'(\epsilon_j)|^{1/2},
\]

for any \(N_1, N_2 \in \mathbb{N}\).

By Hölder’s and Young’s inequalities, we get

\[
|I|_1 \leq C(A^{1-N_1} + A^{1-N_2})\|f\|_2 \|g\|_2 \leq C\beta C^{\beta}_{j,m} \|f\|_2 \|g\|_2, \tag{5.2}
\]

where the second inequality holds whenever \(N_1, N_2 \geq (1 + \beta)/(1 - \beta)\).

On the other hand, since

\[
\text{supp}(\mathcal{F}[1_{2^m, n+k_1} \ast \phi_{2^m} \cdot f \ast \Phi]) \subset \{\xi \in \mathbb{R} : 3/8 \leq |\xi| \leq 17/8\}
\]

and

\[
\text{supp}(\mathcal{F}[1_{2^m, \gamma'(\epsilon_j)-1, n+k_2} \ast \phi_{2^m, \gamma'(\epsilon_j)-1} \cdot g \ast \Phi]) \subset \{\xi \in \mathbb{R} : 3/8 \leq |\xi| \leq 17/8\},
\]

we then have

\[
\Pi = \sum_{n \in \mathbb{Z}} \sum_{k_1, k_2 \in \mathbb{Z}} B^\beta_{j,m}(1_{2^m, n+k_1} \ast \phi_{2^m} \cdot f \ast \Phi, \tag{5.3}
\]

where \(B^\beta_{j,m}\) and the Cauchy-Schwarz inequality, we have

\[
\|\Pi\|_1 \leq C\beta C^{\beta}_{j,m} A^2 \|f\|_2 \|g\|_2 = C\beta C^{\beta}_{j,m} \|f\|_2 \|g\|_2. \tag{5.4}
\]

The desired inequality \((5.1)\) follows from \((5.2)\) and \((5.3)\). \(\square\)

6. Proof of Theorem 2.1

We prove Theorem 2.1 in this section. Let \(\rho \in C^\infty_0(\mathbb{R})\) be an odd function supported in \(\{t \in \mathbb{R} : 1/2 \leq |t| \leq 2\}\) and \(\rho_j(t) = 2^j \rho(2^j t)\) such that

\[
1/t = \sum_{j \in \mathbb{Z}} \rho_j(t), \quad \text{if } t \neq 0.
\]

Then

\[
H_\Gamma(f, g)(x) = \sum_{j \geq 0} \int_{-1}^1 f(x - t)g(x - \gamma(t))\rho_j(t) dt.
\]
Let $L \in \mathbb{N}$. If $0 \leq j \leq L$, we can trivially estimate the $L^1$-norm of each summand above by Hölder’s inequality and get a bound in the form of $C\|f\|_2\|g\|_2$. Hence we may assume $j > L$ below. By the Fourier inversion formula we need to estimate

$$\tilde{H}_T(f, g)(x) = \sum_{j > L} \int \int \hat{f}(\xi)\hat{g}(\eta) m_j(\xi, \eta) e^{2\pi i (\xi + \eta)x} \, d\xi \, d\eta,$$

where

$$m_j(\xi, \eta) = \int_\mathbb{R} \rho(t) e^{-2\pi i (2^{-j} \xi t + \eta \gamma (2^{-j} t))} \, dt. \tag{6.1}$$

Let $\tilde{\Phi} \in C_0^\infty(\mathbb{R})$ be an even nonnegative function supported in $\{\xi \in \mathbb{R} : 1/2 \leq |\xi| \leq 2\}$ such that $\hat{\Phi}(\xi/2^m) = 1$, if $\xi \neq 0$.

Let $m, m' \in \mathbb{Z}$. Set $m_{j, m, m'}(\xi, \eta) = \hat{\Phi}(\xi/2^j)\hat{\Phi}(\eta/2^{m'})m_j(\xi, \eta)$, where $\Delta_j$ is defined in Section 2. Then $m_j(\xi, \eta)$ can be decomposed as the sum of

$$m_{j,+,+}(\xi, \eta) = \sum_{m, m' \geq 0} \sum_{|m' - m| < C} m_{j, m, m'}(\xi, \eta),$$

$$m_{j,--,}(\xi, \eta) = \sum_{m < 0} \sum_{m' < 0} m_{j, m, m'}(\xi, \eta),$$

$$m_{j,+,--}(\xi, \eta) = \sum_{m \geq 0} \sum_{m' \leq m - C} m_{j, m, m'}(\xi, \eta),$$

and

$$m_{j,--,+}(\xi, \eta) = \sum_{m \geq 0} \sum_{m \leq m' - C} m_{j, m, m'}(\xi, \eta),$$

where $C$ is a large constant (to be determined later; see (6.5) below). Then

$$\tilde{H}_T(f, g)(x) = \sum_{(s, **) \in \mathcal{A}} \left( \sum_{j > L} \int \int \hat{f}(\xi)\hat{g}(\eta)m_{j, s, **}(\xi, \eta) e^{2\pi i (\xi + \eta)x} \, d\xi \, d\eta \right)$$

$$=: \sum_{(s, **) \in \mathcal{A}} \tilde{H}_{(s, **)}(f, g)(x),$$

where the index set $\mathcal{A}$ is given by

$$\mathcal{A} = \{(+, +), (--), (+, -), (-, +)\}. \tag{6.2}$$

We split $\tilde{H}_T(f, g)(x)$ into two parts:

**Major part**: $(s, **) = (+, +)$;

**Minor part**: $(s, **) = (--), (+, -), and (-, +).$
The essential difficulty in the proof of Theorem 2.1 lies in the estimates of the major part. All our preparations in Section 3-5 are done for it. The minor part can be reduced to classical paraproducts by using the Taylor and Fourier series expansions, and then handled by Theorem 3.4.

The following proposition completes the proof of Theorem 2.1.

**Proposition 6.1.** Using the notations above, we have

(i) Major part: if \((*,**) = (+, +)\), then

\[
\| \widetilde{H}(\ast, \ast\ast)(f, g) \|_1 \leq C \| f \|_2 \| g \|_2.
\]

(ii) Minor part: if \((*, **) \neq (+, +)\), then

\[
\| \widetilde{H}(\ast, \ast\ast)(f, g) \|_r \leq C \| f \|_{p_1} \| g \|_{p_2},
\]

for all \(p_1 > 1\) and \(p_2 > 1\) such that \(1/r = 1/p_1 + 1/p_2\).

The rest of this section is devoted to the proof of this proposition.

### 6.1. Estimates of the major part.

We consider the case \(m, m' \in \mathbb{N}\) with \(|m - m'| \leq C\) in this subsection. Actually it suffices to prove the special case \(m' = m \in \mathbb{N}\) to which we can easily reduce the case \(m' = m + b\) (for each \(1 \leq |b| < C\)) simply by replacing \(\gamma\) by a constant multiple of \(\gamma\). We also notice that there is a symmetry between the two cases: \(t \geq 0\) and \(t \leq 0\) and they can be handled similarly.

With these simplifications it suffices to prove

\[
(6.3) \quad \left\| \sum_{j > L} \sum_{m \in \mathbb{N}} T_{j,m}(f, g) \right\|_1 \leq C \| f \|_2 \| g \|_2,
\]

where

\[
T_{j,m}(f, g)(x) = \iint \hat{f}(\xi) \hat{g}(\eta) \Phi(\frac{2^{-j} \xi}{2^m}) \Phi(\frac{2^{-j} \gamma'(2^{-j}) \eta}{2^m}) m_j^+(\xi, \eta) e^{2\pi i (\xi + \eta)x} d\xi d\eta
\]

with

\[
m_j^+(\xi, \eta) = \int_0^\infty \rho(t) e^{-2\pi i (2^{-j} \xi + \eta(t))} dt.
\]

To prove (6.3) we first apply a change of variables and get

\[
\int \int \hat{f}_{j,m}(\xi) \hat{g}_{j,m}(\eta) \Phi(\eta) e^{2\pi i (2^{-j} + \gamma'(2^{-j})) (\xi + \eta)x} K_{j,m}(\xi, \eta) d\xi d\eta,
\]

where

\[
f_{j,m}(x) = 2^{-j-m} f(2^{-j-m} x),
\]

\[
g_{j,m}(x) = 2^{-j-m} \gamma'(2^{-j}) g(2^{-j-m} \gamma'(2^{-j}) x),
\]

and

\[
K_{j,m}(\xi, \eta) = m_j^+(2^{j+m} \xi, 2^{j+m} \eta/\gamma'(2^{-j})) = \int_0^\infty \rho(t) e^{-2\pi i 2^m (\xi \eta + t(\gamma'(2^{-j}))} dt
\]
with
\[ Q_{2^{-j}}(t) = \gamma(2^{-j}t)/(2^{-j}\gamma'(2^{-j})). \]
Let \( 1_0 \) be the indicator function of \( \{ x \in \mathbb{R} : 1/2 \leq |x| \leq 2 \} \). Then
\[
\|T_{j,m}(f,g)\|_1 = 2^{j+m}|\gamma'(2^{-j})|^{-1/2}\|B_{j,m}^\Phi(F^{-1}[f_{j,m}1_0],F^{-1}[g_{j,m}1_0])\|_1,
\]
\[
\leq C2^{-m/32}2^{j+m}|\gamma'(2^{-j})|^{-1/2}\|f_{j,m}1_0\|_2\|g_{j,m}1_0\|_2,
\]
where we have applied Proposition 4.1 and 5.1 if \( L \) is sufficiently large. Thus,
\[
\left\|\sum_{j>L} \sum_{m \in \mathbb{N}} T_{j,m}(f,g)\right\|_1 \leq C\sum_{m \in \mathbb{N}} 2^{-m/32} \sum_{j>L} \|f\|_2 \|g\|_2.
\]
In the last inequality, we have used the Cauchy-Schwarz inequality and the bound
\[
\sum_{j>L} 1_0(2^{-j-m}\gamma'(2^{-j})\eta) \leq C,
\]
which follows from the condition (2.4) (and also Remark 2.4 (3)). This finishes the estimates of the major part.

6.2. Estimates of the minor part. For the minor part, we begin with \((\ast, \ast\ast) = (-,-)\). Notice
\[
m_{j,-,-}(\xi,\eta) = \sum_{m=-\infty}^{m'} m_{j,m,m'}(\xi,\eta) + \sum_{m'=m'}^{m-1} m_{j,m,m'}(\xi,\eta)
\]
\[
=: m_{j,-,m'}(\xi,\eta) + m_{j,m,-}(\xi,\eta)
\]
The treatments of \( m_{j,-,m'}(\xi,\eta) \) and \( m_{j,m,-}(\xi,\eta) \) are similar. We show how to handle \( m_{j,-,m'}(\xi,\eta) \). Set
\[
\hat{\Psi}(\xi) = \sum_{m \leq 0} \hat{\Phi}(\frac{\xi}{2^m}).
\]
By employing the Taylor expansion, \( m_{j,-,m'}(\xi,\eta) \) is equal to
\[
\sum_{p=0}^{\infty} \sum_{q=0}^{\infty} \frac{1}{p!q!} \hat{\Psi}(\frac{\xi}{2^j+m}) \hat{\Phi}(\frac{\eta}{2^m}) \int \rho(t)(-2\pi i\xi2^{-j}t)^p(2\pi i\eta\gamma(2^{-j}t))^q dt
\]
\[
= \sum_{p=0}^{\infty} \sum_{q=0}^{\infty} c_{j,p,q} \frac{1}{p!q!} 2^{m-(p+q)} N_{j,p,q}(\xi,\eta),
\]
where
\[
(6.4) \quad c_{j,p,q} = \int \rho(t)(-2\pi it)^p(-2\pi i\gamma(2^{-j}t)\Delta_j))^q \, dt
\]
and
\[
N_{j,p,q}(\xi, \eta) = \hat{\Psi}(\frac{\xi}{2^{j+m'}})(\frac{\xi}{2^{j+m'}})^p\hat{\Phi}(\frac{\eta}{2^{m'}\Delta_j})(\frac{\eta}{2^{m'}\Delta_j})^q.
\]
Since $\rho$ is an odd function, $c_{j,0,0} = 0$ for all $j \in \mathbb{Z}$ and thus we do not need to consider $N_{j,0,0}(\xi, \eta)$ for all $j > L$. This yields a decay factor as follows
\[
2^{m'(p+q)} \leq 2^{m'} \quad \text{if} \quad (p, q) \neq (0, 0),
\]
which allows us to sum over $m' \leq 0$ later.

The condition (2.1) gives
\[
|c_{j,p,q}| \leq \|\rho\|_1(4\pi)^p (2\pi C_1)^q
\]
and
\[
\sum_{p,q \geq 0} \frac{1}{p! q!} |c_{j,p,q}| < C < \infty
\]
for some constant $C$ which is independent of $j$.

Set
\[
N_{p,q}(\xi, \eta) = \sum_{j>L} N_{j,p,q}(\xi, \eta) = \sum_{j>L} \hat{\Psi}(\frac{\xi}{2^{j+m'}})(\frac{\xi}{2^{j+m'}})^p\hat{\Phi}(\frac{\eta}{2^{m'}\Delta_j})(\frac{\eta}{2^{m'}\Delta_j})^q.
\]
It suffices to show that $N_{p,q}$, as a bilinear multiplier, maps $L^{p_1} \times L^{p_2}$ to $L^r$ with a bound independent of $m'$. Indeed, the dependence of $m'$ can be removed easily via the following claim:

**Claim 6.2.** Assume $M(\xi, \eta)$, as a symbol for a bilinear multiplier, maps $L^{p_1} \times L^{p_2}$ to $L^r$ with a bound $A$. Here $p_1 > 1$, $p_2 > 1$, and $1/p_1 + 1/p_2 = 1/r$. Let $R > 0$ be any constant. Then $M_R(\xi, \eta) = M(R\xi, R\eta)$ is also a bounded bilinear multiplier which maps $L^{p_1} \times L^{p_2}$ to $L^r$ with the same bound $A$.

Claim 6.2 can be proved by a standard rescaling argument and we omit the details here.

Applying the same arguments to $m_{j,m,-}(\xi, \eta)$, we obtain the corresponding multiplier
\[
\tilde{N}_{p,q}(\xi, \eta) = \sum_{j>L} \hat{\Phi}(\frac{\xi}{2^{j+m-1}})(\frac{\xi}{2^{j+m-1}})^p\hat{\Psi}(\frac{\eta}{2^{m'-1}\Delta_j})(\frac{\eta}{2^{m'-1}\Delta_j})^q.
\]
Again, Claim 6.2 allows us to dispose the factor $2^{m-1}$ on the right hand side.

To sum up, the case $(\ast, \ast\ast) = (-, -)$ is reduced to the problem concerning the boundedness of the bilinear multipliers whose symbols are given by
\[
\sum_{j>L} \hat{\Psi}(\frac{\xi}{2^j})(\frac{\xi}{2^j})^p\hat{\Phi}(\frac{\eta}{\Delta_j})(\frac{\eta}{\Delta_j})^q.
\]
and
\[
\sum_{j > L} \hat{\Phi}(\frac{\xi}{2j}) \hat{\Phi}(\frac{\eta}{2j}) \hat{\Psi}(\frac{\eta}{\Delta_j}) \hat{\Psi}(\frac{\eta}{\Delta_j})^q,
\]
which is covered by Theorem 3.4 as a special case when \((n_1, n_2) = (0, 0)\).

Now we turn to \((\ast, \ast\ast) = (-, +)\). Notice
\[
m_{j, -,+}(\xi, \eta) = \sum_{m' \geq 0} m_{j, -m'}(\xi, \eta)
\]
where
\[
m_{j, -m'}(\xi, \eta) = \sum_{m = -\infty}^{m' - C} m_{j, m, m'}(\xi, \eta).
\]
Applying the Fourier series of \(m_j(\xi, \eta)\) yields
\[
m_{j, -m'}(\xi, \eta) = \sum_{n_1, n_2 \in \mathbb{Z}} a_{n_1, n_2} e^{2\pi i n_1 \frac{\xi}{2j + m - C} + n_2 \frac{\eta}{2m' \Delta_j}}.
\]

Since
\[
|D_t (\eta \gamma (2^{-j} t))| = \left| \frac{\eta}{\Delta_j} \right| > 2^9 |D_t (\xi 2^{-j} t)|
\]
given \(C\) sufficiently large, integration by parts gives the following fast decay
\[
|a_{n_1, n_2}| \leq C_N (1 + n_1^2 + n_2^2)^{-N} 2^{-m'N} \quad \text{for any} \quad N \in \mathbb{N}.
\]
Consequently, we only need to deal with a fixed \(m'\) and a fixed pair \((n_1, n_2)\). Set
\[
N_{n_1, n_2}(\xi, \eta) = \sum_{j > L} \hat{\Phi}(\frac{\xi}{2j + m' - C}) e^{2\pi i n_1 \frac{\xi}{2j + m' - C}} \hat{\Phi}(\frac{\eta}{2m' \Delta_j}) e^{2\pi i n_2 \frac{\eta}{2m' \Delta_j}}.
\]
Similarly, in the case \((\ast, \ast\ast) = (+, -)\) we need to handle the following multiplier
\[
N'_{n_1, n_2}(\xi, \eta) = \sum_{j > L} \hat{\Phi}(\frac{\xi}{2j + m}) e^{2\pi i n_1 \frac{\xi}{2j + m}} \hat{\Psi}(\frac{\eta}{2m - C \Delta_j}) e^{2\pi i n_2 \frac{\eta}{2m - C \Delta_j}}.
\]
By Claim 6.2 the factor \(2^{m'}\) in (6.6) and the factor \(2^m\) in (6.7) are disposable. Thus we reduce our problem to establishing the boundedness of the paraproducts whose symbols are given by
\[
\sum_{j > L} \hat{\Phi}(\frac{\xi}{2j - C}) e^{2\pi i n_1 \frac{\xi}{2j - C}} \hat{\Phi}(\frac{\eta}{\Delta_j}) e^{2\pi i n_2 \frac{\eta}{\Delta_j}}.
\]
and
\begin{equation}
\sum_{j>L} \hat{\Phi} \left( \frac{\xi}{2^j} \right) e^{2\pi i n_1 \xi} \hat{\Psi} \left( \frac{\eta}{2^{-C} \Delta_j} \right) e^{2\pi i n_2 \frac{\eta}{2^{-C} \Delta_j}},
\end{equation}
with bounds whose growth rates are at most a polynomial of \((1+n_1^2+n_2^2)\), which also follows from Theorem 3.4. Indeed, Theorem 3.4 is applicable to the multiplier (6.9), since the sequence \(\{2^{-C} \Delta_j\}_{j>L}\) satisfies the condition (3.4). For the multiplier (6.8), one can perform a rescaling argument \((\xi, \eta) \rightarrow (2^{C} \xi, 2^{C} \eta)\) and notice the sequence \(\{2^{C} \Delta_j\}_{j>L}\) satisfies the condition (3.4), which allows us to apply Theorem 3.4 again. This finishes the estimates of the minor part.

7. The bilinear maximal functions

This section is devoted to the proof of Theorem 2.2. The arguments we use here are essentially those from [12, Section 7]. Recall that
\begin{equation}
M_\Gamma(f, g)(x) = \sup_{0<\epsilon<1} \epsilon^{-1} \int_0^\epsilon f(x-t)g(x-\gamma(t)) \, dt,
\end{equation}
where we have assumed that \(f\) and \(g\) are both nonnegative. We want to show
\begin{equation}
\|M_\Gamma(f, g)\|_1 \leq C \|f\|_2 \|g\|_2.
\end{equation}
The proof of (7.1) is almost identical to the proof of Theorem 2.1 in Section 6. One noticeable difference is that the minor part of the bilinear maximal function can be controlled pointwisely by the Hardy-Littlewood maximal function.

Let \(\rho \in C^\infty([1/4, 1])\) be nonnegative with \(\rho(1/2) = 1\). Set \(\rho_j(t) = 2^j \rho(2^j t)\). It suffices to establish the boundedness of the following maximal function
\begin{equation}
M^*(f, g)(x) = \sup_{j>L} \int f(x-t)g(x-\gamma(t))\rho_j(t) \, dt =: \sup_{j>L} M_j(f, g)(x),
\end{equation}
where \(L \in \mathbb{N}\) is sufficiently large.

Like what we did in Section 6 we have
\begin{align*}
M_j(f, g)(x) &= \int \int \hat{f}(\xi)\hat{g}(\eta)m_j(\xi, \eta) e^{2\pi i (\xi+\eta)x} \, d\xi \, d\eta \\
&= \sum_{(*) \in A} \int \int \hat{f}(\xi)\hat{g}(\eta)m_{j, \star, \star}(\xi, \eta) e^{2\pi i (\xi+\eta)x} \, d\xi \, d\eta \\
&=: \sum_{(*) \in A} M_{j, \star, \star}(f, g)(x),
\end{align*}
where \(m_j(\xi, \eta)\) and \(A\) are as defined in (6.1) and (6.2) respectively. It suffices to prove
\begin{equation}
\left\| \sup_j |M_{j, \star, \star}(f, g)| \right\|_1 \leq C \|f\|_2 \|g\|_2
\end{equation}
for each pair \((\star, \star) \in A\).
Lemma 7.1 (Minor part). Let \( M(f) \) denote the Hardy-Littlewood maximal function of \( f \). If \( (\ast, \ast) \neq (+, +) \), then there is a constant \( C > 0 \) such that
\[
\sup_{j > L} \left| M_{j, \ast, \ast}(f, g)(x) \right| \leq CM(f(x)M(g)(x)).
\]

Assume this lemma for a moment. The Cauchy-Schwarz inequality and the Hardy-Littlewood maximal function yield
\[
\left\| \sup_{j > L} \left| M_{j, \ast, \ast}(f, g) \right| \right\|_p \leq C \| M(f)M(g) \|_p,
\]
\[
\leq C \| M(f) \|_{p_1} \| M(g) \|_{p_2}
\]
\[
\leq C \| f \|_{p_1} \| g \|_{p_2}.
\]
In particular, if \( (\ast, \ast) \neq (+, +) \), (7.2) follows from the inequality above by taking \( (r, p_1, p_2) = (1, 2, 2) \).

Proposition 7.2 (Major part). If \( (\ast, \ast) = (+, +) \), we have
\[
\left\| \sup_{j > L} \left| M_{j, +, +}(f, g) \right| \right\| \leq C \| f \|_2 \| g \|_2.
\]

This proposition is essentially the result obtained in Subsection 6.1. Indeed, we have the following pointwise estimate
\[
\sup_{j > L} \left| M_{j, +, +}(f, g)(x) \right| \leq \sum_{j > L} \left| M_{j, +, +}(f, g)(x) \right|.
\]
Then (6.3) implies
\[
\left\| \sup_{j > L} \left| M_{j, +, +}(f, g) \right| \right\|_1 \leq \left\| \sum_{j > L} \left| M_{j, +, +}(f, g) \right| \right\|_1 \leq C \| f \|_2 \| g \|_2.
\]

It remains to verify Lemma 7.1. We consider the case \( (\ast, \ast) = (+, -) \) first. Most of the calculation in Subsection 6.2 remains valid. In particular, we have
\[
m_{j, -, -}(\xi, \eta) := \sum_{p, q \in \mathbb{N}} c_{j, p, q} \frac{1}{p! q!} \hat{\Psi}(\frac{\xi}{2^j})(\frac{\xi}{2^j})^p \hat{\Psi}(\frac{\eta}{2^j})(\frac{\eta}{2^j})^q.
\]
Notice
\[
\sup_{\xi \in \mathbb{N}} \left| \int \hat{\Psi}(\frac{\xi}{2^j})(\frac{\xi}{2^j})^p \hat{f}(\xi)e^{2\pi i \xi x} d\xi \right| \leq C_1 M(f)(x)
\]
and
\[
\sup_{\eta \in \mathbb{N}} \left| \int \hat{\Psi}(\frac{\eta}{2^j})(\frac{\eta}{2^j})^q \hat{g}(\eta)e^{2\pi i \eta x} d\eta \right| \leq C_2 M(g)(x),
\]
where \( C_1 \) and \( C_2 \) depend at most exponentially on \( p \) and \( q \). Thus
\[
\sup_{\eta \in \mathbb{N}} \left| \int \hat{f}(\xi)\hat{g}(\eta)m_{j, -, -}(\xi, \eta)e^{2\pi i (\xi + \eta)x} d\xi d\eta \right| \leq CM(f(x)M(g)(x),
\]
which proves Lemma 7.1 when $(\ast, \ast) = (\ast, \ast)$.

The cases $(\ast, +)$ and $(+, -)$ are exactly the same. We only show how to handle the former one. Using the same notations as in Subsection 6.2, we have

\[ m_{j, -}((\xi, \eta)) = \sum_{m' \geq 0} m_{j, -}((\xi, \eta)) \]

and

\[ m_{j, +}((\xi, \eta)) = \hat{\Psi}(\frac{\xi}{2j + m' - C}) \hat{\Phi}(\frac{\eta}{2m' \Delta_j}) \sum_{n_1, n_2 \in \mathbb{Z}} a_{n_1, n_2} e^{2\pi i (n_1 \frac{\xi}{2j + m' - C} + n_2 \frac{\eta}{2m' \Delta_j})}, \]

where

\[ |a_{n_1, n_2}| \leq C_N(1 + n_1^2 + n_2^2)^{-N} 2^{-m'N} \text{ for any } N \in \mathbb{N}. \]

Then

\[ \sup_{j \in \mathbb{Z}} \left| \int \hat{f}(\xi)e^{2\pi i \xi x} \frac{\xi}{2j + m' - C} e^{2\pi i n_1 \xi} d\xi \right| \leq C(1 + n_1^2)M(f)(x) \]

and

\[ \sup_{j \in \mathbb{Z}} \left| \int \hat{g}(\eta)e^{2\pi i \eta x} \frac{\eta}{2m' \Delta_j} e^{2\pi i n_2 \eta} d\eta \right| \leq C(1 + n_2^2)M(g)(x). \]

In the statements (7.6) and (7.7), we have applied the following fact

\[ \sup_{t > 0} |f * \Omega_t(x - \frac{n}{t})| \leq C_\Omega(1 + n^2)M(f)(x), \]

where

\[ \Omega_t(x) = t\Omega(tx). \]

Then (7.3), (7.4), (7.5), (7.6) and (7.7) yield

\[ \sup_{j > L} |M_{j, -}((f, g))(x)| \leq CM(f)(x)M(g)(x), \]

as desired.
