Proximal point algorithm, Douglas–Rachford algorithm and alternating projections: a case study

Heinz H. Bauschke∗, Minh N. Dao†, Dominikus Noll‡ and Hung M. Phan§

January 26, 2015

Abstract

Many iterative methods for solving optimization or feasibility problems have been invented, and often convergence of the iterates to some solution is proven. Under favourable conditions, one might have additional bounds on the distance of the iterate to the solution leading thus to worst case estimates, i.e., how fast the algorithm must converge.

Exact convergence estimates are typically hard to come by. In this paper, we consider the complementary problem of finding best case estimates, i.e., how slow the algorithm has to converge, and we also study exact asymptotic rates of convergence. Our investigation focuses on convex feasibility in the Euclidean plane, where one set is the real axis while the other is the epigraph of a convex function. This case study allows us to obtain various convergence rate results. We focus on the popular method of alternating projections and the Douglas–Rachford algorithm. These methods are connected to the proximal point algorithm which is also discussed. Our findings suggest that the Douglas–Rachford algorithm outperforms the method of alternating projections in the absence of constraint qualifications. Various examples illustrate the theory.

2010 Mathematics Subject Classification: Primary 65K05; Secondary 65K10, 90C25.

Keywords: alternating projections, convex feasibility problem, convex set, Douglas–Rachford algorithm, projection, proximal mapping, proximal point algorithm, proximity operator.

1 Introduction

Three algorithms

Let $X$ be a Euclidean space, with inner product $\langle \cdot, \cdot \rangle$ and induced norm $\| \cdot \|$, and let $f : X \to ]-\infty, +\infty[$ be convex, lower semicontinuous, and proper. A classical method for finding a minimizer of $f$ is the proximal point algorithm (PPA). It requires using the proximal point mapping (or proximity operator) which was pioneered by Moreau [13]:

**Fact 1.1 (proximal mapping)** For every $x \in X$, there exists a unique point $p = P_f(x) \in X$ such that
\[
\min_{y \in X} f(y) + \frac{1}{2} \| x - y \|^2 = f(p) + \frac{1}{2} \| x - p \|^2.
\]
The induced operator $P_f : X \to X$ is firmly nonexpansive\(^1\), i.e., $(\forall x \in X)(\forall y \in X) \| P_f(x) - P_f(y) \|^2 + \| (\text{Id} - P_f)x - (\text{Id} - P_f)y \|^2 \leq \| x - y \|^2$.

The proximal point algorithm was proposed by Martinet [12] and further studied by Rockafellar [16]. Nowadays numerous extensions exist; however, here we focus only on the most basic instance of PPA:

**Fact 1.2 (proximal point algorithm (PPA))** Let $f : X \to ]-\infty, +\infty[$ be convex, lower semicontinuous, and proper. Suppose that $Z$, the set of minimizers of $f$, is nonempty, and let $x_0 \in X$. Then the sequence generated by
\[
(\forall n \in \mathbb{N}) \quad x_{n+1} = P_f(x_n)
\]
converges to a point in $Z$ and it satisfies
\[
(\forall z \in Z)(\forall n \in \mathbb{N}) \| x_{n+1} - z \|^2 + \| x_n - x_{n+1} \|^2 \leq \| x_n - z \|^2.
\]

An ostensibly quite different type of optimization problem is, for two given closed convex nonempty subsets $A$ and $B$ of $X$, to find a point in $A \cap B \neq \emptyset$. Let us present two fundamental algorithms for solving this convex feasibility problem. The first method was proposed by Bregman [8].

**Fact 1.3 (method of alternating projections (MAP))** Let $a_0 \in A$ and set
\[
(\forall n \in \mathbb{N}) \quad a_{n+1} = P_A P_B(a_n).
\]
Then $(a_n)_{n \in \mathbb{N}}$ converges to a point $a_\infty \in C = A \cap B$. Moreover,
\[
(\forall c \in C)(\forall n \in \mathbb{N}) \| a_{n+1} - c \|^2 + \| a_{n+1} - P_B a_n \|^2 + \| P_B a_n - a_n \|^2 \leq \| a_n - c \|^2.
\]

The second method is the celebrated Douglas–Rachford algorithm. The next result can be deduced by combining [11] and [4].

\(^1\) Note that if $f = \iota_C$ is the indicator function of a nonempty closed convex subset of $X$, then $P_f = P_C$, where the $P_C$ is the nearest point mapping or projector of $C$; the corresponding reflector is $R_C = 2P_C - \text{Id}$. 
Fact 1.4 (Douglas–Rachford algorithm (DRA)) Set \( T = \text{Id} - P_A + P_B R_A \), let \( z_0 \in X \), and set
\[
(\forall n \in \mathbb{N}) \quad a_n = P_A z_n \quad \text{and} \quad z_{n+1} = T z_n.
\]
Then \((z_n)_{n \in \mathbb{N}}\) converges to some point in \( z_\infty \in \text{Fix } T = (A \cap B) + N_{A-B}(0) \), and \((a_n)_{n \in \mathbb{N}}\) converges to \( P_A z_\infty \in A \cap B \).

Again, there are numerous refinements and adaptations of MAP and DRA; however, it is here not our goal to survey the most general results possible \(^3\) but rather to focus on the speed of convergence. We will make this precise in the next subsection.

Goal and contributions

Most rate-of-convergence results for PPA, MAP, and DRA take the following form: If some additional condition is satisfied, then the convergence of the sequence is at least as good as some form of “fast” convergence (linear, superlinear, quadratic etc.). This can be interpreted as a worst case analysis. In the generality considered here \(^3\) we are not aware of results that approach this problem from the other side, i.e., that address the question: Under which conditions is the convergence no better than some form of “slow” convergence? This concerns the best case analysis.

Ideally, one would like an exact asymptotic rate of convergence in the sense of \(^{14}\) below.

While we do not completely answer these questions, we do set out to tackle them by providing a case study when \( X = \mathbb{R}^2 \) is the Euclidean plane, the set \( A = \mathbb{R} \times \{0\} \) is the real axis, and the set \( B \) is the epigraph of a proper lower semicontinuous convex function \( f \). We will see that in this case MAP and DRA have connections to the PPA applied to \( f \). We focus in particular on the case not covered by conditions guaranteeing linear convergence of MAP or DRA \(^5\). We originally expected the behaviour of MAP and DRA in cases of “bad geometry” to be similar \(^6\). It came to us as surprise that this appears not to be the case. In fact, the examples we provide below suggest that DRA performs significantly better than MAP. Concretely, suppose that \( B \) is the epigraph of the function \( f(x) = (1/p)|x|^p \), where \( 1 < p < +\infty \). Since \( A = \mathbb{R} \times \{0\} \), we have that \( A \cap B = \{(0,0)\} \) and since \( f'(0) = 0 \), the “angle” between \( A \) and \( B \) at the intersection is 0. As expected MAP converges sublinearly (even logarithmically) to 0. However, DRA converges faster in all cases: superlinearly (when \( 1 < p < 2 \)), linearly (when \( p = 2 \)) or logarithmically (when \( 2 < p < +\infty \)). This example is deduced by general results we obtain on exact rates of convergence for PPA, MAP and DRA.

---

\(^2\) Here \( \text{Fix } T = \{ x \in X \mid x = Tx \} \) is the set of fixed points of \( T \), and \( N_{A-B}(0) \) stands for the normal cone of the set \( A \cap B = \{ a - b : a \in A, b \in B \} \) at 0.

\(^3\) See, e.g. \(^8\) for various more general variants of PPA, MAP, and DRA.

\(^4\) Some results are known for MAP when the sets are linear subspaces; however, the slow (sublinear) convergence can only be observed in infinite-dimensional Hilbert space; see \(^7\) and references therein.

\(^5\) Indeed, the most common sufficient condition for linear convergence in either case is \( \text{ri}(A) \cap \text{ri}(B) \neq \emptyset \); see \(^5\) Theorem 3.21 for MAP and \(^{14}\) or \(^6\) Theorem 8.5(ii) for DRA.

\(^6\) This expectation was founded in the similar behaviour of MAP and DRA for two subspaces; see \(^2\).
Organization

The paper is organized as follows. In Section 2, we provide various auxiliary results on the convergence of real sequences. These will make the subsequent analysis of PPA, MAP, and DRA more structured. Section 3 focuses on the PPA. After reviewing results on finite, super-linear, and linear convergence, we exhibit a case where the asymptotic rate is only logarithmic. We then turn to MAP in Section 4 and provide results on the asymptotic convergence. We also draw the connection between MAP and PPA and point out that a result of Güler is sharp. In Section 5, we deal with DRA, draw again a connection to PPA and present asymptotic convergence. The notation we employ is fairly standard and follows, e.g., [15] and [3].

2 Auxiliary results

In this section we collect various results that facilitate the subsequent analysis of PPA, MAP and DRA. We begin with the following useful result which appears to be part of the folklore.

Fact 2.1 (generalized Stolz–Cesàro theorem) Let \((a_n)_{n \in \mathbb{N}}\) and \((b_n)_{n \in \mathbb{N}}\) be sequences in \(\mathbb{R}\) such that \((b_n)_{n \in \mathbb{N}}\) is unbounded and either strictly monotone increasing or strictly monotone decreasing. Then

\[
\lim_{n \to \infty} \frac{a_{n+1} - a_n}{b_{n+1} - b_n} \leq \lim_{n \to \infty} \frac{a_n}{b_n} \leq \lim_{n \to \infty} \frac{a_{n+1} - a_n}{b_{n+1} - b_n},
\]

where the limits may lie in \([-\infty, +\infty]\).

Setting \((b_n)_{n \in \mathbb{N}} = (n)_{n \in \mathbb{N}}\) in Fact 2.1, we obtain the following:

Corollary 2.2 The following inequalities hold for an arbitrary sequence \((x_n)_{n \in \mathbb{N}}\) in \(\mathbb{R}\):

\[
\lim_{n \to \infty} (x_{n+1} - x_n) \leq \lim_{n \to \infty} \frac{x_n}{n} \leq \lim_{n \to \infty} \frac{x_n}{n} \leq \lim_{n \to \infty} (x_{n+1} - x_n).
\]

For the remainder of this section, we assume that

\[
g: \mathbb{R}_+ \to \mathbb{R}_+ \text{ is increasing and } H \text{ is an antiderivative of } -1/g.
\]

Example 2.3 (x^q) Let \(g(x) = x^q\) on \(\mathbb{R}_+\), where \(1 \leq q < \infty\). If \(q > 1\), then \(-1/g(x) = -x^{-q}\) and we can choose \(H(x) = x^{1-q}/(q-1)\) which has the inverse \(H^{-1}(x) = 1/((q-1)x^{1/(q-1)})\). If \(q = 1\), then we can choose \(H(x) = -\ln(x)\) which has the inverse \(H^{-1}(x) = \exp(-x)\).

Proposition 2.4 Let \((\beta_n)_{n \in \mathbb{N}}\) and \((\delta_n)_{n \in \mathbb{N}}\) be sequences in \(\mathbb{R}_+\), and suppose that

\[
(\forall n \in \mathbb{N}) \quad \beta_{n+1} = \beta_n - \delta_n g(\beta_n).
\]

Then the following hold:

Since we were able to locate only an online reference, we include a proof in Appendix A.
(i) \((\forall n \in \mathbb{N})\) \(\delta_n \leq H(\beta_{n+1}) - H(\beta_n) \leq \delta_{n+1} \frac{\beta_n - \beta_{n+1}}{\beta_{n+1} - \beta_{n+2}} = \delta_n \frac{g(\beta_n)}{g(\beta_{n+1})}.

(ii) \(\lim_{n \to \infty} \delta_n \leq \lim_{n \to \infty} \frac{H(\beta_n)}{n} \leq \lim_{n \to \infty} \frac{H(\beta_n)}{n} \leq \lim_{n \to \infty} \frac{H(\beta_n)}{n} \leq \lim_{n \to \infty} \frac{g(\beta_n)}{g(\beta_{n+1})}.

(iii) If \((\delta_n)_{n \in \mathbb{N}}\) is convergent, say \(\delta_n \to \delta_\infty\), and \(\frac{g(\beta_n)}{g(\beta_{n+1})} \to 1\), then \(\frac{H(\beta_n)}{n} \to \delta_\infty\).

\[\text{Proof.}\] For every \(n \in \mathbb{N}\), we have

\[(10a)\] \(\delta_n = \frac{\beta_n - \beta_{n+1}}{g(\beta_n)} \leq \int_{\beta_n}^{\beta_{n+1}} \frac{dx}{g(x)} = H(\beta_{n+1}) - H(\beta_n)

\[(10b)\] \(\leq \frac{\beta_n - \beta_{n+1}}{g(\beta_{n+1})} = \delta_{n+1} \frac{\beta_n - \beta_{n+1}}{\beta_{n+1} - \beta_{n+2}} = \delta_n \frac{g(\beta_n)}{g(\beta_{n+1})}.

Hence [1] holds. Combining with [7], we obtain [2]. Finally, [iii] follows from [ii].

\[\text{Corollary 2.5}\] Let \((x_n)_{n \in \mathbb{N}}\) and \((\delta_n)_{n \in \mathbb{N}}\) be sequences in \(\mathbb{R}_+\) such that

\[(11)\] \((\forall n \in \mathbb{N})\) \(x_n = x_{n+1} + \delta_n g(x_{n+1}).

Then the following hold:

(i) \((\forall n \in \mathbb{N})\) \(\delta_n \frac{g(x_{n+1})}{g(x_n)} \leq H(x_{n+1}) - H(x_n) \leq \delta_n.

(ii) \(\lim_{n \to \infty} \delta_n \frac{g(x_{n+1})}{g(x_n)} \leq \lim_{n \to \infty} \frac{H(x_n)}{n} \leq \lim_{n \to \infty} \frac{H(x_n)}{n} \leq \lim_{n \to \infty} \frac{g(x_{n+1})}{g(x_n)} \leq \lim_{n \to \infty} \frac{H(x_n)}{n} \to \delta_\infty.

(iii) If \((\delta_n)_{n \in \mathbb{N}}\) is convergent, say \(\delta_n \to \delta_\infty\), and \(\frac{g(x_{n+1})}{g(x_n)} \to 1\), then \(\frac{H(x_n)}{n} \to \delta_\infty\).

\[\text{Proof.}\] Indeed, set \((\forall n \in \mathbb{N})\) \(\varepsilon_n = \delta_n \frac{g(x_{n+1})}{g(x_n)}\) and rewrite the update

\[(12)\] \(x_{n+1} = x_n - \delta_n \frac{g(x_{n+1})}{g(x_n)} g(x_n) = x_n - \varepsilon_n g(x_n).

Now apply Proposition 2.4.

\[\text{Definition 2.6 (types of convergence)}\] Let \((\alpha_n)_{n \in \mathbb{N}}\) be a sequence in \(\mathbb{R}_+\) such that \(\alpha_n \to 0\), and suppose there exist \(1 \leq q < +\infty\) such that

\[(13)\] \(\frac{\alpha_{n+1}}{\alpha_n^q} \to c \in \mathbb{R}_+\).

Then the convergence of \((\alpha_n)_{n \in \mathbb{N}}\) to 0 is:

(i) with order \(q\) if \(q > 1\) and \(c > 0\);
(ii) superlinear if \( q = 1 \) and \( c = 0 \);

(iii) linear if \( q = 1 \) and \( 0 < c < 1 \);

(iv) sublinear if \( q = 1 \) and \( c = 1 \);

(v) logarithmic if it is sublinear and

\[
|\alpha_{n+1} - \alpha_{n+2}|/|\alpha_n - \alpha_{n+1}| \to 1.
\]

If \( (\beta_n)_{n \in \mathbb{N}} \) is also a sequence in \( \mathbb{R}_+ \), it is convenient to define

\[
\alpha_n \sim \beta_n \iff \lim_{n \to \infty} \frac{\alpha_n}{\beta_n} \in \mathbb{R}_+.
\]  

The following example exhibits a case where we obtain a simple exact asymptotic rate of convergence.

**Example 2.7** Let \( (x_n)_{n \in \mathbb{N}} \) and \( (\delta_n)_{n \in \mathbb{N}} \) be sequences in \( \mathbb{R}_+ \), and let \( 1 < q < \infty \). Suppose that

\[
\delta_n \to \delta_\infty \in \mathbb{R}_+, \quad \frac{x_n}{x_{n+1}} \to 1, \quad \text{and} \quad (\forall n \in \mathbb{N}) \ x_n = x_{n+1} + \delta_n x_n^q.
\]

Then \( x_n \to 0 \) logarithmically,

\[
\frac{x_n}{\left(\frac{1}{n}\right)^{1/(q-1)}} \to \frac{1}{((q-1)\delta_\infty)^{1/(q-1)}} \quad \text{and} \quad x_n \sim \left(\frac{1}{n}\right)^{1/(q-1)}.
\]

**Proof.** Suppose that \( g(x) = x^q \) and note that \( g(x_{n+1})/g(x_n) = (x_{n+1}/x_n)^q \to 1^q = 1 \). This implies that \( x_n \to 0 \) logarithmically. Finally, (16) follows from Example 2.3, Corollary 2.5 and (14).

We conclude this section with some one-sided versions which are useful for obtaining information about how fast or slow a sequence must converge.

**Corollary 2.8** Let \( (\beta_n)_{n \in \mathbb{N}} \) and \( (\rho_n)_{n \in \mathbb{N}} \) be sequences in \( \mathbb{R}_+ \), and suppose that

\[
(\forall n \in \mathbb{N}) \ \beta_{n+1} \leq \beta_n - \rho_n g(\beta_n) \quad \text{and} \quad \rho = \lim_{n \to \infty} \rho_n \in \mathbb{R}_+.
\]

Then

\[
(\forall \varepsilon \in \mathbb{R}_+) \ (\exists m \in \mathbb{N}) (\forall n \geq m) \ \beta_n \leq H^{-1}(n(\rho - \varepsilon)).
\]

**Proof.** Observe that

\[
(\forall n \in \mathbb{N}) \ \beta_{n+1} = \beta_n - \delta_n g(\beta_n), \quad \text{where} \quad \delta_n = \frac{\beta_n - \beta_{n+1}}{g(\beta_n)} \geq \rho_n.
\]

Hence, by Proposition 2.4 \( \rho \leq \lim_{n \to \infty} H(\beta_n)/n \). Let \( \varepsilon \in \mathbb{R}_+ \). Then there exists \( m \in \mathbb{N} \) such that \( (\forall n \geq m) \ \rho \geq H(\beta_n)/n \iff H^{-1}(n(\rho - \varepsilon)) \geq \beta_n. \)
Example 2.9 Let \((\beta_n)_{n \in \mathbb{N}}\) and \((\rho_n)_{n \in \mathbb{N}}\) be sequences in \(\mathbb{R}_+\), let \(1 \leq q < \infty\), and suppose that
\[
(\forall n \in \mathbb{N}) \ \beta_{n+1} \leq \beta_n - \rho_n \beta_n^q \quad \text{and} \quad \rho = \lim_{n \to \infty} \rho_n \in \mathbb{R}_+.
\]
Let \(0 < \epsilon < \rho\). Then there exists \(m \in \mathbb{N}\) such that the following hold:

(i) If \(q > 1\), then \((\forall n \geq m) \ \beta_n \leq \frac{1}{((q-1)n(\rho - \epsilon))^{1/(q-1)}} = O\left(\frac{1}{n^{1/(q-1)}}\right)\).

(ii) If \(q = 1\), then \((\forall n \geq m) \ \beta_n \leq \gamma^n\), where \(\gamma = \exp(\epsilon - \rho) \in ]0,1[\).

Consequently, the convergence of \((\beta_n)_{n \in \mathbb{N}}\) to 0 is at least sublinear if \(q > 1\) and at least linear if \(q = 1\).

Proof. Combine Example 2.3 with Corollary 2.8.

Remark 2.10 Example 2.9(i) can also be deduced from [7, Lemma 4.1]; see also [1].

Corollary 2.11 Let \((\beta_n)_{n \in \mathbb{N}}\) and \((\rho_n)_{n \in \mathbb{N}}\) be sequences in \(\mathbb{R}_+\), and suppose that
\[
(\forall n \in \mathbb{N}) \ \beta_n \geq \beta_{n+1} \geq \beta_n - \rho_n g(\beta_n) \quad \text{and} \quad \bar{p} = \lim_{n \to \infty} \rho_n g(\beta_n) / g(\beta_{n+1}) \in \mathbb{R}_+.
\]
Then
\[
(\forall \epsilon \in \mathbb{R}_+)(\exists m \in \mathbb{N})(\forall n \geq m) \ \beta_n \geq H^{-1}(n(\bar{p} + \epsilon)).
\]

Proof. Observe that
\[
(\forall n \in \mathbb{N}) \ \beta_{n+1} = \beta_n - \delta_n g(\beta_n), \quad \text{where} \quad \delta_n = \frac{\beta_n - \beta_{n+1}}{g(\beta_n)} \leq \rho_n.
\]

Hence, by Proposition 2.4 \(\lim_{n \to \infty} H(\beta_n) / n \leq \bar{p}\). Let \(\epsilon \in \mathbb{R}_+\). Then there exists \(m \in \mathbb{N}\) such that \((\forall n \geq m) \ \bar{p} + \epsilon \geq H(\beta_n) / n \Leftrightarrow H^{-1}(n(\bar{p} + \epsilon)) \leq \beta_n\).

Example 2.12 Let \((\beta_n)_{n \in \mathbb{N}}\) and \((\rho_n)_{n \in \mathbb{N}}\) be sequences in \(\mathbb{R}_+\), let \(1 \leq q < \infty\), and suppose that
\[
(\forall n \in \mathbb{N}) \ \beta_n \geq \beta_{n+1} \geq \beta_n - \rho_n \beta_n^q \quad \text{and} \quad \bar{p} = \lim_{n \to \infty} \rho_n \beta_n^q / \beta_{n+1}^q \in \mathbb{R}_+.
\]
Let \(\epsilon \in \mathbb{R}_+\). Then there exists \(m \in \mathbb{N}\) such that the following hold:

(i) If \(q > 1\), then \((\forall n \geq m) \ \beta_n \geq \frac{1}{((q-1)n(\bar{p} + \epsilon))^{1/(q-1)}}\).

(ii) If \(q = 1\), then \((\forall n \geq m) \ \beta_n \geq \gamma^n\), where \(\gamma = \exp(-\bar{p} - \epsilon) \in ]0,1[\).

Consequently, the convergence of \((\beta_n)_{n \in \mathbb{N}}\) to 0 is at best sublinear if \(q > 1\) and at best linear if \(q = 1\).

Proof. Combine Example 2.3 with Corollary 2.11.
3 Proximal point algorithm (PPA)

This section focuses on the proximal point algorithm. We assume that

\[
f : \mathbb{R} \to [\infty, +\infty]
\]

is convex, lower semicontinuous, proper, with

\[
f(0) = 0 \quad \text{and} \quad f(x) > 0 \quad \text{when} \quad x \neq 0.
\]

Given \(x_0 \in \mathbb{R}\), we will study the basic proximal point iteration

\[
(\forall n \in \mathbb{N}) \quad x_{n+1} = P_f(x_n).
\]

Note that if \(x > 0\) and \(y < 0\), then

\[
f(y) + \frac{1}{2}|x - y|^2 > f(0) + \frac{1}{2}|x - 0|^2 \geq f(P_f x) + \frac{1}{2}|x - P_f x|^2.
\]

Hence the behaviour of \(f|_{\mathbb{R}^-}\) is irrelevant for the determination of \(P_f|_{\mathbb{R}^+}\) (and an analogous statement holds for the determination of \(P_f|_{\mathbb{R}^-}\))! For this reason, we restrict our attention to

\[
x_0 \in \mathbb{R}^+
\]

is the starting point of the proximal point algorithm. The general theory (Fact 1.2) then yields

\[
x_0 \geq x_1 \geq \cdots \geq x_n \downarrow 0.
\]

In this section, it will be convenient to additionally assume that

\[
f \text{ is an even function;}
\]

although, as mentioned, the behaviour of \(f|_{\mathbb{R}^-}\) is actually irrelevant because \(x_0 \in \mathbb{R}^+\).

Combining the assumption that 0 is the unique minimizer of \(f\) with [15, Theorem 24.1], we learn that

\[
0 \in \partial f(0) = [f^-_+(0), f^+_+(0)] \cap \mathbb{R} = [-f^+_+(0), f^+_+(0)] \cap \mathbb{R}.
\]

We start our exploration by discussing convergence in finitely many steps.

**Proposition 3.1 (finite convergence)** We have \(x_n \to 0\) in finitely many steps, regardless of the starting point \(x_0 \in \mathbb{R}^+\), if and only if

\[
0 < f^+_+(0),
\]

in which case \(P_f x_n = 0 \iff x_n \leq f^+_+(0)\).

**Proof.** Let \(x > 0\). Then \(P_f x = 0 \iff x \in 0 + \partial f(0) \iff x \leq f^+_+(0)\) by (31).

Suppose first that \(f^+_+(0) > 0\). Then, by (31), \(0 \in \mathrm{int} \partial f(0)\) and, using (29), there exists \(n \in \mathbb{N}\) such that \(x_n \leq f^+_+(0)\). It follows that \(x_{n+1} = x_{n+2} = \cdots = 0\). (Alternatively, this follows from a much more general result of Rockafellar; see [16, Theorem 3] and also Remark 3.4 below.)

Now assume that there exists \(n \in \mathbb{N}\) such that \(P_f x_n = 0\) and \(x_n > 0\). By the above, \(x_n \leq f^+_+(0)\) and thus \(f^+_+(0) > 0\). \(\blacksquare\)
An extreme case occurs when $f'_+(0) = +\infty$ in Proposition 3.1.

**Example 3.2 ($\iota\{0\}$ and the projector)** Suppose that $f = \iota\{0\}$. Then $P_f = P_{\{0\}}$ and $(\forall n \geq 1) x_n = 0$.

**Example 3.3 ($|x|^1$ and the thresholder)** Suppose that $f = |\cdot|$ in which case $\partial f(0) = [-1, 1]$ and $f'_+(0) = 1$. Proposition 3.1 guarantees finite convergence of the PPA. Indeed, either a direct argument or [3, Example 14.5] yields

(33) $P_f : x \mapsto \begin{cases} x - \frac{x}{|x|}, & \text{if } |x| > 1; \\ 0, & \text{otherwise}, \end{cases}$

Consequently, $x_n = 0$ if and only if $n \geq \lceil |x_0| \rceil$.

**Remark 3.4** In [16, Theorem 3], Rockafellar provided a very general sufficient condition for finite convergence of the PPA (which works actually for finding zeros of a maximally monotone operator defined on a Hilbert space). In our present setting, his condition is

(34) $0 \in \text{int} \partial f(0)$.

By Proposition 3.1, this is also a condition that is necessary for finite convergence.

Thus, we assume from now on that $f'_+(0) = 0$, or equivalently (since $f$ is even and by (31)), that

(35) $f'(0) = 0$.

in which case finite convergence fails and thus

(36) $x_0 > x_1 > \cdots > x_n \downarrow 0$.

We now have the following sufficient condition for linear convergence. The proof is a refinement of the ideas of Rockafellar in [16].

**Proposition 3.5 (sufficient condition for linear convergence)** Suppose that

(37) $\lambda = \lim_{x \to 0} \frac{f(x)}{x^2} \in ]0, +\infty]$.

Then the following hold:

(i) If $\lambda < +\infty$, then there exists $\alpha_0 \in \left[ \frac{1}{\lambda}, \frac{1}{\lambda} \right]$ such that

(38) $(\forall \epsilon > 0)(\exists m \in \mathbb{N})(\forall n \geq m) |x_{n+1}| \leq \frac{\alpha_0}{\sqrt{1 + \alpha_0^2(1 + 2\lambda - 2\epsilon)}} |x_n|$. 

9
(ii) If $\lambda = +\infty$, then

$$
(39) \quad (\forall \alpha > 0)(\forall \epsilon > 0)(\exists m \in \mathbb{N})(\forall n \geq m) \quad |x_{n+1}| \leq \frac{\alpha}{\sqrt{1 + \alpha^2(1 + 2\lambda - \epsilon)}} |x_n|.
$$

Proof. By [16, Remark 4 and Proposition 7], there exists $\alpha_0 \in \left[ \frac{1}{2\sqrt{\lambda}}, 1 \right]$ such that $(\partial f)^{-1}$ is Lipschitz continuous at 0 with every modulus $\alpha > \alpha_0$. Let $\alpha > \alpha_0$. Then there exists $\tau > 0$ such that

$$
(40) \quad (\forall |x| < \tau)(\forall z \in (\partial f)^{-1}(x)) \quad |z| \leq \alpha |x|.
$$

Since $x_n \to 0$ by [16 Theorem 2] (or (36)), there exists $m \in \mathbb{N}$ such that $(\forall n \geq m) \quad |x_n - x_{n+1}| \leq \tau$. Let $n \geq m$. Noticing that $x_n \in (\text{Id} + \partial f)(x_{n+1})$, we have

$$
(41) \quad x_{n+1} \in (\partial f)^{-1}(x_n - x_{n+1}).
$$

It follows by (40) that

$$
(42) \quad |x_{n+1}| \leq \alpha |x_n - x_{n+1}|.
$$

Since $x_n - x_{n+1} \in \partial f(x_{n+1})$, we have

$$
(43) \quad \langle x_n - x_{n+1}, x_{n+1} \rangle = \langle x_n - x_{n+1}, x_{n+1} - 0 \rangle \geq f(x_{n+1}) - f(0) = f(x_{n+1}).
$$

Now for every $\epsilon > 0$, employing (37) and increasing $m$ if necessary, we can and do assume that

$$
(44) \quad (\forall n \geq m) \quad \langle x_n - x_{n+1}, x_{n+1} \rangle \geq \left( \lambda - \frac{\epsilon}{2} \right) |x_{n+1}|^2.
$$

Let $n \geq m$. Combining (42) and (44), we obtain

$$
(45a) \quad |x_n|^2 = |x_{n+1}|^2 + |x_n - x_{n+1}|^2 + 2 \langle x_n - x_{n+1}, x_{n+1} \rangle
$$

$$
(45b) \quad \geq |x_{n+1}|^2 + \frac{1}{\alpha^2} |x_n|^2 + (2\lambda - \epsilon) |x_{n+1}|^2
$$

$$
(45c) \quad = \left( \frac{1 + \alpha^2(1 + 2\lambda - \epsilon)}{\alpha^2} \right) |x_{n+1}|^2.
$$

This gives

$$
(46) \quad |x_{n+1}| \leq \frac{\alpha}{\sqrt{1 + \alpha^2(1 + 2\lambda - \epsilon)}} |x_n|
$$

and hence (39) holds. Now assume that $\lambda < +\infty$ so that $a_0 > 0$. Since $\alpha \mapsto \frac{\alpha}{\sqrt{1 + \alpha^2(1 + 2\lambda - \epsilon)}} = \frac{1}{\sqrt{\frac{1}{\alpha^2} + \frac{1}{1 + 2\lambda - \epsilon}}} \quad \text{is strictly increasing on } \mathbb{R}_+$, we note that the choice $\alpha = a_0 / \sqrt{1 - \epsilon a_0^2} > a_0$ yields (38).
Remark 3.6 Assume that \( f \) is differentiable on \( U = [0, \delta[, \) where \( \delta \in \mathbb{R}_{++} \). Then \( f'(x) > 0 \) on \( U \). Note that \( \lim_{x \downarrow 0} f'(x) = f''(0) \). Therefore, L'Hôpital's rule shows that if \( f''(0) \) exists in \([0, +\infty]\), then
\[
\lambda = \frac{1}{2} f''(0)
\]
in (37). A sufficient condition for \( \lambda \) to exist is to assume that the function \( f(x)/x^2 \) is monotone on \( U \), which in turn happens when \( 2f(x) - xf'(x) \) is either nonnegative or nonpositive on \( U \) by using the quotient rule.

Although we won’t need it in the remainder of this paper, we point out that the proof of Proposition 3.5 still works in a more general setting leading to the following result:

Corollary 3.7 Let \( H \) be a real Hilbert space, and let \( f : H \to [-\infty, +\infty] \) be convex, lower semicontinuous and proper such that 0 is the unique minimizer of \( f \). Assume also that
\[
\lambda = \lim_{0 \neq x \to 0} \frac{f(x)}{\|x\|^2} \in [0, +\infty].
\]
Then there exists \( \alpha_0 \in \left[\frac{1}{2}, \frac{1}{\lambda}\right] \) such that
\[
(\forall \alpha > \alpha_0)(\forall \epsilon > 0)(\exists m \in \mathbb{N})(\forall n \geq m) \quad \|x_{n+1}\| \leq \frac{\alpha}{\sqrt{1 + \alpha^2(1 + 2\lambda - \epsilon)}}\|x_n\|.
\]
If \( \lambda < +\infty \), then eventually
\[
\|x_{n+1}\| \leq \frac{\alpha_0}{\sqrt{1 + \alpha_0^2}}\|x_n\|,
\]
a result which can also be deduced from [16, Theorem 2].

We now discuss powers of the absolute value function.

Example 3.8 (\(|x|^2 \) and linear convergence) Suppose that \( f(x) = x^2 \). Then \( x + f'(x) = 3x \) and hence \( P_f = \frac{1}{3} \text{Id} \). We see that the actual linear rate of convergence of the PPA is
\[
\frac{1}{3}.
\]

Now consider Proposition 3.5 and Corollary 3.7. Then clearly \( \lambda = 1 \) in (37) and hence \( \alpha_0 \in \left[\frac{1}{2}, 1\right] \). In fact, since \( \partial f = 2 \text{Id} \) and so \( (\partial f)^{-1} = \frac{1}{2} \text{Id} \), we know that the tightest choice for \( \alpha_0 \) is \( \alpha_0 = \frac{1}{2} \). The linear rate obtained by (50) is \((1/2)/\sqrt{1 + (1/2)^2}, \) i.e.,
\[
\frac{1}{\sqrt{5}}.
\]
Let us compare to the linear rate provided by Proposition 3.5 where, for every \( \epsilon > 0 \), we obtain \((1/2)/\sqrt{1 + (1/2)^2(1 + 2 - 2\epsilon)} = 1/\sqrt{7 - 2\epsilon} \). From the proof of Proposition 3.5, we see that we can here actually set \( \epsilon = 0 \); thus, the rate provided is
\[
\frac{1}{\sqrt{7}}.
\]
In summary, $1/\sqrt{7}$, the rate from Proposition 3.5, is better than $1/\sqrt{5}$, which comes from (50); however, even the former does not capture the true rate $1/3$.

**Example 3.9 ($|x|^q$, where $1 < q < 2$, and superlinear convergence)**

Suppose that $f(x) = |x|^q$, where $1 < q < 2$. Note that $\lambda = +\infty$ and thus $\alpha_0 = 0$ in (38). In passing, we point out that we cannot use $\alpha_0$ itself in (38) because it would imply finite convergence which does not occur by (36). Set $\phi(x) = x + qx^{q-1}$ and note that $(\forall n \in \mathbb{N})$ $x_n = \phi(x_{n+1})$. Now set also $\psi(x) = qx^{q-1}$, and assume that a sequence $(\rho_n)_{n \in \mathbb{N}}$ satisfies $(\forall n \in \mathbb{N})$ $\rho_n = \psi(\rho_{n+1})$. The sequence $(\rho_n)_{n \in \mathbb{N}}$ can be thought of as an approximation of $(x_n)_{n \in \mathbb{N}}$. It has the advantage that the implicit recursion is invertible and solvable; indeed one may verify by induction that

\begin{equation}
(\forall n \in \mathbb{N}) \quad \rho_n = \rho_0^{1/(q-1)^{n}} (1/q)^{(1/(q-1)^{n-1})/(2-q)};
\end{equation}

Assume furthermore that $\rho_0 = x_0$ is sufficiently close to 0. Since $\phi$ and $\psi$ are increasing and $\phi > \psi > 0$ on $\mathbb{R}_{++}$, we deduce that $(\forall n \geq 1)$ $x_n < \rho_n$. Therefore,

\begin{equation}
(\forall n \in \mathbb{N}) \quad \frac{x_n}{\rho_n} = \frac{\phi(x_{n+1})}{\psi(x_{n+1})} \left( \frac{x_{n+1}}{\rho_{n+1}} \right)^{q-1} > \left( \frac{x_{n+1}}{\rho_{n+1}} \right)^{q-1},
\end{equation}

which implies that

\begin{equation}
0 < \frac{x_n}{\rho_n} < \left( \frac{x_1}{\rho_1} \right)^{1/(q-1)^{n-1}} \to 0
\end{equation}

because $1/(q-1) > 1$. Let $n \in \mathbb{N}$. It follows from $x_n = x_{n+1} + qx_{n+1}^{q-1} > x_{n+1}$ and $1 < q < 2$ that $x_{n+1}^{q-1} < x_n x_{n+1}^{q-1}$, and so

\begin{equation}
\frac{x_n}{x_{n-1}} = \frac{x_{n+1} + qx_{n+1}^{q-1}}{x_n + qx_n^{q-1}} < \frac{x_{n+1}^{q-1}}{x_n^{q-1}}.
\end{equation}

This gives $\frac{\sum_{1/(q-1)}^{x_n}}{x_{1/(q-1)}} < \frac{x_n}{x_{n-1}}$; hence,

\begin{equation}
\frac{x_n}{x_{1/(q-1)}} < \frac{x_n^{1/(q-1)}}{x_n^{1/(q-1)}}.
\end{equation}

On the other hand, $x_n = x_{n+1} + qx_{n+1}^{q-1} > qx_{n+1}^{q-1}$, which yields $(\frac{x_n}{q})^{1/(q-1)} > x_{n+1}$ and hence $\frac{x_{n+1}}{x_n^{1/(q-1)}} < q^{1/(1-q)}$. The sequence $(x_{n+1}/(x_n^{1/(q-1)}))_{n \in \mathbb{N}}$ is thus increasing and bounded above, and so it converges to some $\mu > 0$. We obtain that $x_n \to 0$ superlinearly with order $1/(q-1)$.

**Example 3.10 ($|x|^q$, where $2 < q$, and logarithmic convergence)**

Suppose that $f(x) = |x|^q$, where $2 < q < +\infty$. Because $(\forall n \in \mathbb{N})$ $x_n = x_{n+1} + qx_{n+1}^{q-1}$, we have $x_n/x_{n+1} = 1 + qx_{n+1}^{q-2} \to 1$. It thus follows from Example 2.7 that $x_n \to 0$ logarithmically and

\begin{equation}
\frac{x_n}{((\frac{1}{q})^{1/(q-2)})} \to \frac{1}{((q-2)q)^{1/(q-2)}}.
\end{equation}
Let us summarize what we found out in the previous three examples about the behaviour of the PPA applied to $|x|^q$:

| $q$ | PPA convergence of $x_n \to 0$ for $f(x) = |x|^q$ |
|-----|--------------------------------------------------|
| $1 < q < 2$ | superlinear with order $1/(q - 1)$ |
| $q = 2$ | linear with rate $1/3$ |
| $2 < q < +\infty$ | logarithmic |

## 4 Method of Alternating Projections (MAP)

We now turn to the method of alternating projections. As in Section 3, we assume without loss of generality that

$$f: \mathbb{R} \to ]-\infty, +\infty[$$

is convex, lower semicontinuous, and proper, with

$$f \text{ even, } f(0) = 0, f > 0 \text{ otherwise, and } f'(0) = 0.$$ 

Furthermore, we set

$$A = \mathbb{R} \times \{0\} \quad \text{and} \quad B = \text{epi } f.$$

The projection onto $A$ is very simple:

$$P_A: \mathbb{R}^2 \to \mathbb{R}^2: (x, r) \mapsto (x, 0).$$

We now turn to $P_B$.

**Fact 4.1** (See [3, Proposition 9.18 and Proposition 28.28]) Let $(x, r) \in (\text{dom } f \times \mathbb{R}) \setminus B$. Then

$$P_B(x, r) = (y, f(y)), \text{ where } y \text{ satisfies } x \in y + (f(y) - r)\partial f(y). \text{ Moreover, } r < f(y) \text{ and } (\forall z \in \text{dom } f) (z - y)(x - y) \leq (f(z) - f(y))(f(y) - r).$$

**Corollary 4.2** Suppose that $f$ is differentiable at 0, let $(x, r) \in (\text{dom } f \times \mathbb{R}) \setminus B$, and set $(y, f(y)) = P_B(x, r)$. Then $y = 0$ if $x = 0$, and $y$ lies strictly between $x$ and 0 otherwise. Furthermore, $x^2 + r^2 \geq y^2 + f(y)^2 + (x - y)^2 + (r - f(y))^2$.

**Proof.** We use Fact 4.1. Observe that $r < f(y)$ and hence that $f(y) - r > 0$. Choosing $z = 0$ gives $-y(x - y) \leq -f(y)(f(y) - r) \leq 0$. If $x = 0$, this implies $y^2 \leq 0$, and so $y = 0$. Assume that $x \neq 0$. Then $y \neq 0$ since $y = 0$ implies $x = 0 + (f(0) - r)f'(0) = 0$. We obtain $-f(y)(f(y) - r) < 0$, and then $-y(x - y) < 0$, i.e., $y(x - y) > 0$. It follows that $y \in ]0, x[$ if $x > 0$, and $y \in ]x, 0[$ if $x < 0$. Finally, since $P_B$ is firmly nonexpansive (see, e.g., [3, Proposition 4.8]) and $P_B(0, 0) = (0, 0)$, we obtain

$$\|(x, r) - (0, 0)\|^2 \geq \|(y, f(y)) - (0, 0)\|^2 + \|(x, r) - (y, f(y))\|^2,$$

which completes the proof. \[\blacksquare\]
We now turn to the sequence generated by the method of alternating projections. We assume without loss of generality that
\[(63a) \quad x_0 \in \mathbb{R}^{++} \cap \text{dom } f, \quad a_0 = (x_0, 0) \in A, \]
and
\[(63b) \quad (\forall n \in \mathbb{N}) \quad a_{n+1} = P_A P_B (a_n) = (x_{n+1}, 0). \]

Combining Fact 1.3, (60) and (63), we learn that
\[(64) \quad x_0 > x_1 > \cdots > x_n \downarrow 0. \]

We are ready for our first result on the lack of linear convergence for MAP.

**Theorem 4.3** The following hold:
\[(65) \quad (\forall n \in \mathbb{N}) \quad x_{n+1} (x_{n+1} - x_n) + f^2 (x_{n+1}) \leq 0, \]
\[(66) \quad (\forall n \in \mathbb{N}) \quad x_n = x_{n+1} + f (x_{n+1}) x_n^*, \quad \text{where } x_n^* \in \partial f (x_{n+1}), \]
and \(x_n \to 0\) sublinearly, i.e.,
\[(67) \quad \frac{x_{n+1}}{x_n} \to 1. \]

If \(f\) is differentiable on some interval \([0, \delta]\), where \(\delta \in \mathbb{R}^{++}\), and there exists \(q \in \mathbb{R}\) such that
\[(68) \quad \lim_{x \downarrow 0} \frac{f(x)f'(x)}{x^q} = c_q \in \mathbb{R}^{++}, \]
then \(x_n \to 0\) logarithmically, i.e.,
\[(69) \quad \frac{x_{n+1} - x_{n+2}}{x_n - x_{n+1}} \to 1. \]

**Proof.** Corollary 4.2 implies (65). Using Fact 4.1 we have (66), which yields
\[(70) \quad \frac{x_n}{x_{n+1}} = 1 + \frac{f(x_{n+1}) - f(0)}{x_{n+1}} x_n^* \to 1 + f'(0) f'(0) = 1 \]
because of \(f'(0) = 0\) and [3, Proposition 17.32]. This gives (67). Now suppose that \(f\) is differentiable on \([0, \delta]\) and (68) holds. Hence, using also (66),
\[(71) \quad \frac{x_{n+1} - x_{n+2}}{x_n - x_{n+1}} = \frac{f(x_{n+2}) f'(x_{n+2})}{f(x_{n+1}) f'(x_{n+1})} \left( \frac{x_{n+2}}{x_{n+1}} \right)^q \to \frac{c_q}{c_q} \cdot 1^q = 1, \]
as claimed. \(\blacksquare\)
Remark 4.4 The function $f$ satisfies \((68)\) with \(q = 2a - 1\) and \(c_q = a \varphi^2(0)\) whenever \(f(x) = x^a \varphi(x)\), where \(a \in \mathbb{R} \setminus \{0\}\), \(\delta \in \mathbb{R}^+\), \(\varphi\) is differentiable on \([0, \delta]\), \(\varphi'\) is continuous at 0, and \(\varphi(0) \neq 0\).

Proposition 4.5 Suppose that \(f\) is differentiable on \([0, \delta]\), where \(\delta \in \mathbb{R}^+\). Set
\[
(72) \quad (\forall q \in [1, +\infty) \quad c_q = \lim_{x \downarrow 0} \frac{f(x)}{x^q},
\]
where \(c_q\) is either undefined if the limit does not exist or in \([0, +\infty]\). Let \(q \in [1, +\infty]\). Then the following hold:

(i) \(c_1 = 0\). If \(c_q = 0\), then \(c_q' = 0\) for \(1 \leq q' < q\). If \(c_q > 0\), then \(c_q' = +\infty\) for \(q' > q\).

(ii) If \(c_q = 0\), then
\[
(73) \quad \frac{x_n - 1}{x_{n+1}^{q-1} x_{n+1}^q} \to 0
\]
and
\[
(74) \quad (\forall \varepsilon \in \mathbb{R}^+)(\exists m \in \mathbb{N})(\forall n \geq m) \quad x_n \geq \begin{cases} 
\left(\exp(-\varepsilon)\right)^n, & \text{when } q = 1; \\
\frac{1}{((q-1)n\varepsilon)^{1/(q-1)}}, & \text{when } q > 1.
\end{cases}
\]

(iii) If \(c_q > 0\), then \(q > 1\) and \(\frac{x_n}{(\frac{1}{n})^{1/(q-1)}} \to \frac{1}{((q-1)c_q)^{1/(q-1)}}\).

Proof. \(\Box\) Using L'Hôpital's rule, we have \(\lim_{x \downarrow 0} \frac{f(x)}{x} = \lim_{x \downarrow 0} \frac{f'(x)}{1} = f'(0) = 0\) and hence \(c_1 = \lim_{x \downarrow 0} \frac{f(x)}{x} = 0\). The remaining statements follow now readily.

(ii) It follows from \((66)\) that
\[
(75) \quad \frac{x_n}{x_{n+1}^{q-1}} = \frac{f(x_{n+1}) f'(x_{n+1})}{x_{n+1}^q} \to c_q = 0;
\]
thus, \((73)\) holds. Now write
\[
(76) \quad x_{n+1} = x_n - \frac{f(x_{n+1}) f'(x_{n+1})}{x_{n+1}^q} \left(\frac{x_{n+1}}{x_n}\right)^q x_{n+1}^q = x_n - \rho_n x_{n+1}^q
\]
and note that \(\rho_n \to 0\) because \(x_{n+1}/x_n \to 1\) and \(c_q = 0\). Thus, \((74)\) holds due to Example 2.12.

(iii) We must have \(q > 1\) since otherwise \(c_q = c_1 = 0\) by \(\Box\) which is absurd. From \((66)\), we have
\[
(77) \quad \frac{x_n}{x_{n+1}} = 1 + \frac{f(x_{n+1}) f'(x_{n+1})}{x_{n+1}} \to 1
\]
and also, for every \( n \in \mathbb{N} \),

\[
(78)\quad x_n = x_{n+1} + f(x_{n+1})f'(x_{n+1}) = x_{n+1} + \frac{f(x_{n+1})f'(x_{n+1})}{x_{n+1}} x_n.
\]

The conclusion therefore follows from Example 2.7. \( \square \)

**Example 4.6** (\( \frac{1}{p} |x|^p \), where \( p > 1 \)) Suppose that \( f(x) = \frac{1}{p} |x|^p \), where \( 1 < p < +\infty \). Let \( x \in \mathbb{R}^+ \). Then \( f(x) = \frac{1}{p} x^p \) and \( f'(x) = x^{p-1} \). Setting \( q = 2p - 1 > 1 \), we have \( c_q = \frac{1}{p} > 0 \), and so \( x_n \to 0 \) logarithmically, using Theorem 4.3. Moreover, by Proposition 4.5(iii),

\[
(79)\quad \frac{x_n}{(\frac{1}{n})^{1/(2p-2)}} \to \frac{1}{\left(\frac{2p-2}{p}\right)^{1/(2p-2)}}.
\]

For a couple of cases, one can actually invert (66) and simplify (79):

\[
(80)\quad p = \frac{3}{2} \Rightarrow \frac{x_n}{1/n} \to \frac{3}{2} \quad \text{and} \quad x_{n+1} = \sqrt{9 + 24x_n} - 3;\]

and

\[
(81)\quad p = 2 \Rightarrow \frac{x_n}{1/\sqrt{n}} \to 1 \quad \text{and} \quad x_{n+1} = \frac{1}{3} \left(27 x_n + 3 \sqrt{81 x_n^2 + 24}\right)^{2/3} - 6.
\]

**Example 4.7** (\( R - \sqrt{R^2 - x^2} \)) Suppose that \( R \in \mathbb{R}^+ \) and that \( f(x) = R - \sqrt{R^2 - x^2} \) on its domain \([-R, R]\). Let \( n \in \mathbb{N} \). Then \( f'(x) = \frac{x}{\sqrt{R^2 - x^2}} \), and by (66),

\[
(82)\quad x_n = x_{n+1} + \left(R - \sqrt{R^2 - x_{n+1}^2}\right) \frac{x_{n+1}}{R^2 - x_{n+1}^2} = \frac{Rx_{n+1}}{\sqrt{R^2 - x_{n+1}^2}}.
\]

It follows that

\[
(83)\quad x_{n+1} = \frac{Rx_n}{\sqrt{x_n^2 + R^2}},
\]

and also \( \frac{R^2}{x_{n+1}^2} = 1 + \frac{R^2}{x_n^2} \). Hence, \( \frac{R^2}{x_n^2} = n + \frac{R^2}{x_0^2} \) which yields the explicit formula

\[
(84)\quad x_n = \frac{Rx_0}{\sqrt{nx_0^2 + R^2}} = \frac{R}{\sqrt{n + (R/x_0)^2}} \sim \frac{R}{\sqrt{n}},
\]

which shows that \( x_n \to 0 \) logarithmically.

**Example 4.8** Suppose that \( f(x) = \exp(|x|) - |x| - 1 \). Then \( f(x)f'(x) = \frac{1}{2} x^3 + \frac{15}{12} x^4 + \frac{5}{24} x^5 + O(x^6) \) on \( \mathbb{R}^+ \). Thus, Proposition 4.5(iii) with \( q = 3 \) and \( c_q = \frac{1}{2} \) yields \( x_n/(1/\sqrt{n}) \to 1 \).
Example 4.9 Suppose that \( f = \cosh \). Then \( f(x)f'(x) = \frac{1}{2}x^3 + \frac{1}{8}x^5 + O(x^7) \) and hence again by Proposition 4.5(iii) with \( q = 3 \) and \( c_q = \frac{1}{2} \) yields \( x_n/(1/\sqrt{n}) \to 1 \).

Example 4.10 (extremely slow convergence) Suppose that \( f(x) = \exp(-x^{-2}) \) with domain \([-\sqrt{2/3}, \sqrt{2/3}]\). Then \( c_q = 0 \) in Proposition 4.5(ii) and hence, according to (73),

\[
\frac{x_n - 1}{x_n^{q-1}} \to 0 \quad \text{for every } q > 1.
\]

Furthermore, the convergence \((x_n)_{n\in\mathbb{N}}\) to 0 is extremely slow in the sense that

\[
\frac{1}{x_n} \leq O(n^{1/p}) \quad \text{for every } p > 0.
\]

Remark 4.11 (MAP sequence is essentially a PPA sequence) Note that, by (66),

\[
(\forall n \in \mathbb{N}) \quad x_n \in (\text{Id} + f \cdot \partial f)(x_{n+1}) = (\text{Id} + \partial_2 f^2)(x_{n+1})
\]

and so

\[
(\forall n \in \mathbb{N}) \quad x_{n+1} = P_{1/2 f^2}(x_n).
\]

Since \( f^2 \) is convex (by, e.g., [3, Proposition 8.19]), we see that the sequence \((a_n)_{n\in\mathbb{N}} = (x_n, 0)_{n\in\mathbb{N}}\) generated by MAP is essentially the same as the sequence generated by PPA for the function \( 1/2 f^2 \)! This useful connection will be further discussed after we recall a special case of a result due to G"üler.

Fact 4.12 (G"üler) (See [10, Theorem 3.1].) Let \( H \) be a real Hilbert space, let \( f : H \to ]-\infty, +\infty] \) be convex, lower semicontinuous, and suppose that the sequence \((x_n)_{n\in\mathbb{N}}\) generated by the PPA converges (strongly) to some minimizer \( z \) of \( f \). Then \( f(x_n) - f(z) = o(1/n) \), i.e., \( n(f(x_n) - f(z)) \to 0 \).

Combining Remark 4.11 with Fact 4.12 results in the following:

**Corollary 4.13** The MAP sequence \((a_n)_{n\in\mathbb{N}} = (x_n, 0)_{n\in\mathbb{N}}\) satisfies

\[
n f^2(x_n) \to 0.
\]

**Example 4.14 (\(1/p|x|^p \) revisited)** Suppose that \( f(x) = \frac{1}{p}|x|^p \), where \( 1 < p \). By Example 4.6

\[
x_n \sim \left( \frac{1}{n} \right)^{1/(2p-2)}.
\]

Then (89) becomes

\[
n f^2(x_n) \sim nx_n^{2p} \sim \frac{1}{n^{1/(p-1)}} \to 0.
\]

Note that this also shows that this consequence of Fact 4.12 is *sharp* in the sense that it cannot be improved to \( n^{1+\epsilon} f^2(x_n) \to 0 \), where \( \epsilon > 0 \). (Indeed, if \( n^{1+\epsilon} f^2(x_n) \to 0 \), then we obtain a contradiction for sufficiently large \( p \).)
Finally, we investigate the Douglas–Rachford algorithm. As in Section 4, we assume that
\[ f : \mathbb{R} \to ]-\infty, +\infty] \]
is convex, lower semicontinuous, and proper,
with
\[ f \text{ even, } f(0) = 0, f > 0 \text{ otherwise, and } f'(0) = 0, \]
and that
\[ A = \mathbb{R} \times \{0\} \text{ and } B = \text{epi } f. \]

We now turn to the sequence generated by the Douglas–Rachford algorithm. We assume that
\[ x_0 \in \mathbb{R}_++ \cap \text{dom } f, \quad r_0 = 0, \quad z_0 = (x_0, 0) \in A, \]
and
\[ (\forall n \in \mathbb{N}) \quad z_{n+1} = Tz_n = (x_{n+1}, r_{n+1}), \]
where
\[ T = \text{Id} - P_A + P_BR_A. \]

Since \( N_{A-B}(0,0) = \mathbb{R}_+(0,1), \) we have
\[ A \cap B = \{(0,0)\} \text{ and } \text{Fix } T = \mathbb{R}_+(0,1), \]

Hence we deduce from Fact 1.4, (92) and (93) that
\[ x_n \to 0 \text{ and } r_n \to r_\infty \in \mathbb{R}_+. \]

Let us now investigate the effect of carrying out one DRA step:

**Corollary 5.1 (one DRA step)** Let \((x, r) \in \mathbb{R}^2,\) set \((x_+, r_+) = T(x, r),\) and suppose that \(0 < x \in \text{dom } f \) and \(0 \leq r < f(x).\) Then there exists \(x_+^* \in \mathbb{R}\) such that
\[ 0 < x_+ = x - r_+ x_+^* < x, \quad x_+^* \in \partial f(x_+) \text{ and } r_+ = r + f(x_+) > r \]
and
\[ x^2 + r^2 \geq x_+^2 + (r_+-r)^2 + (x-x_+)^2 + r_+^2. \]
Proof. First, we note that $R_A(x, r) = (x, -r)$. Set $(y, s) = P_B(x, -r)$. By Fact 4.1
\begin{equation}
(97) \quad y = x - (r + f(y))x^*_+ \text{ for some } x^*_+ \in \partial f(y) \text{ and } s = f(y).
\end{equation}
Now, (93c) gives
\begin{equation}
(98) \quad (x_+, r_+) = (\text{Id} - P_A)(x, r) + P_BR_A(x, r) = (x, r) - (x, 0) + (y, s) = (y, r + s).
\end{equation}
Thus $x_+ = y,$
\begin{equation}
(99) \quad x_+ = x - (r + f(x_+))x^*_+ \text{ and } r_+ = r + f(x_+),
\end{equation}
as claimed. The rest follows from Corollary 4.2. ■

Remark 5.2 (DRA step is related to a PPA step) Consider Corollary 5.1. Then
\begin{equation}
(100) \quad x_+ = P_{rf + \frac{1}{2} f^2}(x) \text{ and } r_+ = r + f(x_+),
\end{equation}
which reveals a connection between the DRA step and the PPA step for $rf + \frac{1}{2} f^2$.

Theorem 5.3 (DRA sequence) The DRA sequence satisfies
\begin{equation}
(101a) \quad x_n \downarrow 0 \text{ and } r_n \uparrow r_\infty \in \mathbb{R}_{++},
\end{equation}
and for every $n \in \mathbb{N}$, there exits $x^*_{n+1} \in \partial f(x_{n+1})$ such that
\begin{equation}
(101b) \quad 0 < x_{n+1} = x_n - r_{n+1}x^*_{n+1} < x_n \quad \text{and} \quad r_{n+1} = r_n + f(x_{n+1}).
\end{equation}
Now suppose that furthermore that $f''_+(0)$ exists in $[0, +\infty]$. Then
\begin{equation}
(102) \quad \frac{x_{n+1}}{x_n} = \frac{1}{1 + r_{n+1}x^*_{n+1}} \rightarrow \frac{1}{1 + r_\infty f''_+(0)}
\end{equation}
and exactly one of the following holds:

(i) $f''_+(0) = +\infty$ and $x_n \rightarrow 0$ superlinearly.

(ii) $f''_+(0) \in \mathbb{R}_{++}$ and $x_n \rightarrow 0$ linearly.

(iii) $f''_+(0) = 0$ and $x_n \rightarrow 0$ sublinearly. If there exists $q \in \mathbb{R}$ such that
\begin{equation}
(103) \quad \lim_{x \downarrow 0} \frac{f''(x)}{x^q} = c \in \mathbb{R}_{++},
\end{equation}
then $x_n \rightarrow 0$ logarithmically; moreover, if additionally $q > 1$, then
\begin{equation}
(104) \quad \frac{x_n}{\left(\frac{1}{n}\right)^{1/(q-1)}} \rightarrow \frac{1}{((q-1)r_\infty c)^{1/(q-1)}}.
\end{equation}
Proof. (101) follows from Corollary 5.1. Divide (101b) by \( x_{n+1} \), solve for \( x_n / x_{n+1} \), then take reciprocals to obtain

\[
\frac{x_{n+1}}{x_n} = \frac{1}{1 + r_{n+1} \frac{x_n}{x_{n+1}}}. 
\]

Now assume that \( f''_+(0) \) exists; it belongs to \([0, +\infty]\) because \( x > 0 \Rightarrow f'(x) > 0 \). Since \( x_n \downarrow 0 \), we see that

\[
\frac{x_n^*}{x_{n+1}} = \frac{f'(x_{n+1})}{x_n} = \frac{f''(x_{n+1}) - f'(0)}{x_{n+1}} 
\]

(106) \( \to f''_+(0) \).

Altogether, we get (102). Items [i] and [ii] are now clear, so let us focus on [iii]. Obviously \( x_n \to 0 \) sublinearly if and only if \( f''_+(0) = 0 \) which we henceforth assume, along with (103). It follows from (101b) that

\[
\frac{x_n - x_{n+2}}{x_n - x_{n+1}} = \frac{r_{n+2} f'(x_{n+2})}{x_{n+1} f'(x_{n+1})} = \frac{r_{n+2} f'(x_{n+2})}{x_{n+1} f'(x_{n+1})} \left( \frac{x_{n+2}}{x_{n+1}} \right)^q \to \frac{r_{\infty} \cdot c}{r_{\infty}} \cdot 1^q = 1; 
\]

hence, \( x_n \to 0 \) logarithmically. Finally assume that \( q > 1 \). Writing (see (101b))

\[
x_n = x_{n+1} + r_{n+1} f'(x_{n+1}) \frac{x_{n+1}^q}{x_{n+1}^q} = x_{n+1} + \delta_n x_{n+1}^q, 
\]

where \( \delta_n \to r_{\infty} c > 0 \), we obtain (104) through Example 2.7. \( \blacksquare \)

Example 5.4 \( \frac{1}{p} |x|^p \), where \( 1 < p < +\infty \) Suppose that \( f(x) = \frac{1}{p} |x|^{p} \), where \( 1 < p < +\infty \). Then exactly one of the following holds:

(i) \( 1 < p < 2 \) and \( \frac{x_{n+1}}{x_n^{1/(p-1)}} \to \frac{1}{r_{\infty}^{1/(p-1)}} > 0 \).

(ii) \( p = 2 \) and \( x_n \to 0 \) linearly with rate \( 1/(1 + r_{\infty}) \).

(iii) \( 2 < p < +\infty, x_n \to 0 \) logarithmically, and \( \frac{x_n}{((p-2)r_{\infty})^{1/(p-2)}} \to 1 \).

Proof. [i] From (101b), we obtain

\[
(\forall n \in \mathbb{N}) \quad x_n = x_{n+1} + r_{n+1} x_{n+1}^{p-1}. 
\]

Since \( x_n \downarrow 0 \) and \( p < 2 \), we have

\[
(\forall \varepsilon > 0) (\exists m \in \mathbb{N}) (\forall n \geq m) \quad 0 < x_{n+1} < \varepsilon x_{n+1}^{p-1}. 
\]

Combining yields \( r_{n+1} x_{n+1}^{p-1} < x_n < (r_{n+1} + \varepsilon) x_{n+1}^{p-1} \). In turn, \( \frac{x_n}{x_{n+1}} \to r_{\infty} > 0 \) and the conclusion follows.

[iii] Clear from (102).

Applying Theorem 5.3 (iii) with \( q = p - 1 > 1 \) and \( c = 1 \). \( \blacksquare \)
Remark 5.5 (comparison MAP vs DR when $f(x) = \frac{1}{p}|x|^p$) Suppose $f(x) = \frac{1}{p}|x|^p$, where $1 < p < +\infty$. According to Example 4.6, the MAP sequence $(x_n)_{n \in \mathbb{N}}$ exhibits logarithmic convergence to 0 and

$$x_n \sim \left(\frac{1}{n}\right)^{1/(2p-2)}.$$  

On the other hand, Example 5.4 yields the following for the DRA sequence $(x_n)_{n \in \mathbb{N}}$:

| $p$         | convergence of the DRA sequence $(x_n)_{n \in \mathbb{N}}$ to 0 |
|------------|-------------------------------------------------------------|
| $1 < p < 2$| superlinear with order $\frac{1}{p-1}$                     |
| $p = 2$    | linear with rate $\frac{1}{1 + r_\infty}$                  |
| $2 < p < +\infty$ | logarithmic and $x_n \sim \left(\frac{1}{n}\right)^{1/(p-2)}$ |

We conclude that in all cases, the DRA sequence converges to 0 faster than the MAP sequence $^8$. To illustrate this, set $x_0 = 1$. Letting the parameter $p$ range from 1 to 3, we show in Figure 1 the first 100 terms of the MAP sequence $(x_n)_{n \in \mathbb{N}}$ and of the DRA sequence $(x_n)_{n \in \mathbb{N}}$.

---

$^8$It is interesting to note that DRA performs better than MAP when $A$ and $B$ are two subspaces with a small Friedrichs angle (see [2] Section 8).
Although both sequences converge to 0, the solution, the stark contrast in their speed of convergence is shown in Figure 2, where we plot the quotient sequence of the MAP sequence divided by the DRA sequence. As predicted by the theory, the terms tend to $+\infty$ when $1 < p < 2$ illustrating the much faster convergence of the DRA sequence.

![Figure 2: The MAP sequence divided by the DRA sequence](image)

**Example 5.6 (comparison MAP vs DR when $f(x) = R - \sqrt{R^2 - x^2}$)**

Suppose that $R \in \mathbb{R}^+$ and that $f(x) = R - \sqrt{R^2 - x^2}$ on its domain $[-R, R]$. According to Example 4.7, the MAP sequence $(x_n)_{n \in \mathbb{N}}$ exhibits logarithmic convergence; in fact,

$$x_n \sim \frac{R}{\sqrt{n}}. \quad (112)$$

We now turn to the DRA sequence $(x_n)_{n \in \mathbb{N}}$. By (101b), we have for every $n \in \mathbb{N}$

$$x_n = x_{n+1} + \left( r_n + R - \sqrt{R^2 - x_{n+1}^2} \right) \frac{x_{n+1}}{\sqrt{R^2 - x_{n+1}^2}} = (r_n + R) \frac{x_{n+1}}{\sqrt{R^2 - x_{n+1}^2}}; \quad (113)$$

consequently,

$$x_{n+1} = \frac{Rx_n}{\sqrt{(r_n + R)^2 + x_n^2}}. \quad (114)$$

Since $f''(x) = R^2/(R^2 - x^2)^{3/2}$, we have $f''(0) = 1/R \in \mathbb{R}^+$ and therefore, by (102), the DRA sequence

$$x_n \to 0 \text{ linearly} \quad (115)$$
with rate $1/(1 + r_\infty/R)$. Once again, the DRA sequence converges much faster than the MAP sequence!

Let us conclude. The results in this paper suggest that, for the convex feasibility problem, DRA outperforms MAP in cases of “bad geometry” (such as the absence of constraint qualifications or a “zero angle” between the constraints at the intersection). Since our proof techniques do not naturally generalize, it would be interesting to study these questions in higher-dimensional space and other classes of convex sets.

Appendix A

Proof of Fact 2.7 (This proof is taken from http://www.imomath.com/index.php?options=686 and included here for completeness as we were not able to locate a book or journal reference.) The second inequality is obvious. We only prove the right inequality since the proof of the left inequality is similar. Without loss of generality, we assume that $b_n \to +\infty$ and that $\lambda = \lim_{n \to \infty} \frac{a_{n+1} - a_n}{b_{n+1} - b_n} < +\infty$. Let $\gamma \in ]\lambda, +\infty[$. Then there exists $m \in \mathbb{N}$ such that $(\forall n \geq m) \frac{a_{n+1} - a_n}{b_{n+1} - b_n} < \gamma$, i.e., $a_{n+1} - a_n < \gamma(b_{n+1} - b_n)$. Let $n > m$. Then $a_n - a_m < \gamma(b_n - b_m)$ and hence

$$\frac{a_n}{b_n} - \frac{a_m}{b_m} < \gamma - \gamma \frac{b_m}{b_n}.$$  

Taking $\lim_{n \to \infty}$ yields

$$\lim_{n \to \infty} \frac{a_n}{b_n} \leq \gamma.$$  

Now let $\gamma \downarrow \lambda$ to complete the proof.  

Appendix B

Proof of Fact 4.12 (This proof is a special case taken from [10] and included here for completeness.) Denote the minimizers of $f$ by $Z$. Let $x \in H$, set $p = P_f x$, $p^* = x - p \in \partial f(p)$, and assume that $p \notin Z$. We have

$$\left(\forall y \in H\right) f(y) - f(p) \geq \langle p^*, y - p \rangle.$$
Hence, for every \( z \in \mathbb{Z} \),
\[
\begin{align*}
(119a) \quad f(z) - f(p) & \geq \langle p^*, z - p \rangle = \langle p^*, z - x \rangle + \langle p^*, x - p \rangle \\
(119b) \quad & \geq -\|p^*\|\|z - x\| + \|p^*\|^2 \geq -\|p^*\|\|z - x\|.
\end{align*}
\]
Since \( f(p) \geq f(z) \), we learn that
\[
\|p^*\| \geq \frac{f(p) - f(z)}{\|x - z\|} \geq 0.
\]
Setting \( y = x \) in (118), we have
\[
(120) \quad f(x) - f(p) \geq \langle p^*, x - p \rangle = \|p^*\|^2.
\]
Therefore,
\[
(121) \quad (f(x) - f(z)) - (f(p) - f(z)) = f(x) - f(p) \geq \|p^*\|^2 \geq \left( \frac{f(p) - f(z)}{\|x - z\|} \right)^2.
\]
It follows that
\[
(122) \quad f(x) - f(z) \geq (f(p) - f(z)) \left( 1 + \frac{f(p) - f(z)}{\|x - z\|^2} \right);
\]
equivalently,
\[
(123) \quad \frac{1}{f(x) - f(z)} \leq \frac{1}{f(p) - f(z)} \left( 1 + \frac{f(p) - f(z)}{\|x - z\|^2} \right)^{-1}.
\]
On the other hand, the definition of the proximal mapping yields
\[
(124) \quad f(p) \leq f(p) + \frac{1}{2} \|x - p\|^2 \leq f(z) + \frac{1}{2} \|x - z\|^2,
\]
which implies
\[
(125) \quad \frac{f(p) - f(z)}{\|x - z\|^2} \leq \frac{1}{2}.
\]
Consider the function \( a(t) = \frac{1}{1 + t} \) with domain \([-1, +\infty[\). Clearly, \( a \) is convex, \( a(0) = 1 \) and \( a(\frac{1}{2}) = \frac{2}{3} \). The line described by \( t \mapsto 1 - \frac{2}{3}t \) goes through the same points and lies between these points above the graph of \( a(\cdot) \) (by convexity). Hence
\[
(126) \quad (\forall 0 \leq t \leq \frac{1}{2}) \quad \frac{1}{1 + t} \leq 1 - \frac{2}{3}t.
\]
Altogether, we deduce that
\[
(127) \quad \varphi(x) = \frac{1}{f(x) - f(z)} \leq \frac{1}{f(p) - f(z)} \left( 1 - \frac{2}{3} \frac{f(p) - f(z)}{\|x - z\|^2} \right)
\]
\[
(128) \quad \leq \frac{1}{f(p) - f(z)} \left( 1 - \frac{2}{3} \frac{f(p) - f(z)}{\|x - z\|^2} \right)
\]
\[
= \varphi(p) - \frac{2}{3\|x - z\|^2}.
\]
Now assume that \( z \leftarrow x_{n+1} = P_f x_n \). Then \( \varphi(x_{n+1}) - \varphi(x_n) \geq \frac{2}{3}\|x_n - z\|^{-2} \to +\infty \). By Corollary 2.2, \( \lim_{n \to +\infty} \frac{\varphi(x_n)}{n} = +\infty \). Now take reciprocals. \( \blacksquare \)
