ABSTRACT
This study aimed to evaluate the content of heavy metals, including cadmium, copper, lead, and zinc in 43 cultivated soil samples collected from Hiep An commune, Duc Trong district, Lam Dong province, Vietnam. The levels of these toxic heavy metals in cultivated soils were evaluated as follows: Cd (0.16 mg/kg to 0.64 mg/kg), Cu (9.0 mg/kg to 41.5 mg/kg), Pb (17.5 mg/kg to 41.0 mg/kg) and Zn (32.1 mg/kg to 90.0 mg/kg). The collected data shows that concentrations of heavy metals in the soil samples were below the allowable limit. Therefore, this area is suited to farm vegetables that are the strength of this region, such as salad, cabbage, tomatoes, cauliflower, kohlrabi. Furthermore, this is a good reference for further studies on the content of trace elements, such as heavy metal toxins in the soil or vegetable/crop grown in the area.

Keywords: Heavy Metal, Cadmium, Lead, Copper, Zinc, Content.

INTRODUCTION
In recent years, the ecological and global public health concerns associated with environmental contamination by heavy metals was increased. Besides, human exposure has risen dramatically as a result of an exponential increase in their use in several agricultural, domestic, industrial, and technological applications. Heavy metals could be released to the environment from geogenic, industrial, agricultural, pharmaceutical, domestic effluents, and atmospheric sources have been reported. Environmental pollution is very prominent in point source areas such as mining, factories and smelters, and other metal-based industrial operations. Heavy metals have affected cellular organelles and components such as cell membranes, endoplasmic reticulum, nuclei, and some enzymes involved in metabolism, detoxification, and damage repair.¹,² Metal ions have interacted with cell components such as DNA and proteins, causing DNA damage and conformational changes that may lead to cell cycle modulation, carcinogenesis.³-⁵ In recent years, Vietnam has become one of the top countries that produce and export agricultural products in the world. For meeting stringent quality standards from fastidious markets like the US, Japan, and Europe, these products must be controlled from farm factors such as soil quality, water quality, and fertilizer quality and cultivation process. Hiep An commune of Duc Trong district has been selected as one of the strategic areas to grow safe vegetables for domestic and export markets.⁶ However, there is a lack of primary survey data on soil agro-culture in this vegetable growing area, especially trace elements as well as toxic heavy metals.

In this paper, the content of cadmium, copper, lead, and zinc in soil samples in the vegetable growing area was evaluated their content in soils. From this, it was concluded that these soils would be suitable for safe vegetable cultivation.

EXPERIMENTAL

Instruments and Chemicals
All used chemicals and solvents were in analytical grade and were used without further purification unless otherwise mentioned. Doubles distilled and degassed water was used throughout, nitric acid HNO₃ 65%,
STUDY OF HEAVY METAL CONTENT

Pb(NO\textsubscript{3})\textsubscript{2}, Cr(NO\textsubscript{3})\textsubscript{3}, Zn(NO\textsubscript{3})\textsubscript{2}, Cu(NO\textsubscript{3})\textsubscript{2}. Atomic Absorption Spectroscopy with 4 hollow cathode lamps: Cu (λ = 324.64 nm); Cd (λ = 228.7 nm); Pb (λ = 217.0 nm) và Zn (λ = 213.52 nm).

Samples Collection
The samples were collected twice in 2018 in Hiep An commune, Duc Trong district, Lam Dong province in Fig.-1 as follows:

Phase-1: In the middle of April (dry season) and
Phase-2: In mid-August (rainy season).

Each sample was taken from 2 soil layers, the surface layer (0-20 cm) and deep layer (25-50 cm). The weight of each sample is about 0.5 kg. The samples were put into PE bags, sealed and marked with serial numbers, taken to the laboratory in Da Lat Nuclear Research Institute. The soil samples were dried at 105°C for 6 hours to obtain the constant weight. The oven-dried material was crushed and sieved through the 2.00 mm mesh to get a representative sample.

Weighed 0.5 g of the oven-dried ground sample using a top-loading balance and placed in a 250 mL beaker, which has been previously washed with nitric acid, and distilled water. The sample was reacted with 5 mL of HNO\textsubscript{3}, 10 ml of concentrated H\textsubscript{2}SO\textsubscript{4}, and 1 mL of HClO\textsubscript{4} using dropping pipette. The mixture is digested in a fume cupboard, heated further until a dense white smoke appears, let the mixture to cool and diluted with distilled water. The solution is filtered through acid-washed Whatman grade 44 filter paper into a 50 ml volumetric flask and diluted to mark the volume. The sample solution was aspirated into the Atomic Absorption Spectroscopic instrument to measure the absorption of elements corresponding to their hollow cathode lamps.

Data Analysis
All data for evaluations were collected from triplicate (n=3) and are presented in average ± standard deviation (SD).

RESULTS AND DISCUSSION

Accuracy of the Method
For testing the accuracy of the method when determining copper, cadmium, lead, and zinc in the study samples, the international standard Soil-7 and Pine-Needles 1575 were selected. Table-1 compares to the recognized values from the international standard samples, and the multi-element standard samples of
Merck differ only from ±5 to ±12%. Hence, the AAS method can be used to determine these metals in real samples.

| Metal | Recognized values (ppm) | Found values (ppm) | Recognized values (ppm) | Found values (ppm) |
|-------|--------------------------|--------------------|--------------------------|--------------------|
| Cd    | 1.3                      | 1.1±0.2            | -                        | 0.025±0.003        |
| Cu    | 11                       | 12.4±1.1           | 3.0±0.3                  | 3.1±0.3            |
| Pb    | 60                       | 56.3±5.4           | 10.8±1.0                 | 11.3±1.1           |
| Zn    | 104                      | 98±10              | 70*                      | 68.9±7.0           |

**Evaluation of the Cd content**

Cadmium is one of the heavy toxic metals that seriously affect human health. It may lead to fatality once inhaled or ingested. After poisoning into the human body, symptoms such as abdominal pain, burning sensation, nausea, vomiting, salivation, muscle cramps, vertigo, shock, loss of consciousness and convulsions usually appear in a short time. Gastrointestinal tract erosion, pulmonary, hepatic, or renal injury and coma, depending on the route of poisoning, could be caused by cadmium. Chronic exposure to cadmium has a depressive effect on levels of norepinephrine, serotonin, and acetylcholine. Cadmium is an element trace in certain foods, such as grains, leafy vegetables, potatoes, seeds, liver, kidney, crustaceans, and mollusks. Cd is capable of being absorbed on the biomass of vegetables. Therefore, the high content of Cd in the soil causes an increase in the possibility of contamination of this metal into vegetables, resulting in risks to human health.

The results of the analysis of Cd content were presented in Table-2. The cadmium content in the surface layer and deep layer of red soil ranges from 0.38 mg/kg to 0.64 mg/kg and from 0.24±0.59 mg/kg. These values in the surface of the red-yellow soil and Gray soil were 0.19±0.37 mg/kg and 0.16±0.19 mg/kg, whereas the Cd content in the deep layer of these two soils was 0.15±0.41 mg/kg and 0.18±0.19 mg/kg, respectively. The Cd content in the cultivated land at Hiep An commune was below the allowed level set by the Ministry of Science and Technology of Vietnam for vegetable cultivation land (2 mg/kg). The pie charts in Fig.-2 and 3 compare the ingredient of Cd in the surface layer and the deep layer between the dry season and the rainy season. The diagram depicts that the content of Cd in the surface layer is higher than it is in the deep layer (in both seasons). This phenomenon could be attributed by adding fertilizers, such as Song Danh organic fertilizer (0.8 mg Cd/kg), Kovac microbial fertilizer (1.2 mg Cd/kg), NPK French (0.2 mg Cd/kg) and Hanexim Ure (0.5 mg Cd/kg). However, the Cd content in the rainy season is less than the dry season. It can be explained that the terrain of this area is relatively steep, causing washing away the elements in the soil.

Evaluation of the Cu Content

For human life, copper is an essential substance. However, at a high level, it can cause anemia, liver and kidney damage, and stomach and intestinal irritation. Besides, this element can affect on a cycle between Cu(II), and Cu(I) in redox reactions of the cuproenzymes. This property of copper can result in the generation of superoxide and hydroxyl radicals. Also, excessive exposure to copper has been linked to cellular damage leading to Wilson’s disease in humans.

Table-3, Fig.-4, and 5 show the Cu content in the cultivated land of Hiep An Commune. The data would seem to suggest that the Cu contents in the red soil were higher than Yellow soil and Gray soil in both seasons, in particular about 2.2 times of Yellow soil and range approximately 3.0-4.0 times of Gray ground. Moreover, several noteworthy results were the Cu content in the surface layer more than the deeper layer. It may be explained that the surface layer is supplemented with copper through fertilizer and pesticides, such as copper sulfate during cultivation. Besides, the obtained Cu values in soil samples of Hiep An commune were higher than agricultural lands in some other places, for example, Da Lat (surface layer: 15.6 ppm, deep layer: 12.6 mg/kg), equivalent to Nha Be agricultural land (24.6mg/kg) and rubber growing land in Dong Nai province (surface layer 21.6 mg/kg, bottom floor 12.8 mg/kg).

Nevertheless, the copper content exceeds the allowable limit for vegetable cultivation by the Vietnam Ministry of Science and Technology (50 mg/kg). The accumulation of copper in the soil may be due to geological nature or because in the cultivation process, many types of fertilizers, pesticides, copper-containing growth solutions have been used.
**Table-3: Cu Content (mg/kg) in Soil**

| Type of Soil | Dry Season | Rainy Season |
|--------------|------------|--------------|
|              | Surface Layer | Deep Layer | Surface Layer | Deep Layer |
| Red soil     | Range 41.5±66.6 | 24.6±50.2 | Range 42.2±62.2 | 30.7±51.5 |
|              | Average 52.7±9.5 | 39.7±6.6 | Average 50.3±7.5 | 38.4±7.3 |
| Red-Yellow Soil | Range 14.1±31.1 | 9.3±25.6 | Range 9.1±32.9 | 8.8±24.0 |
|              | Average 21.3±5.1 | 16.9±4.5 | Average 22.0±6.6 | 17.2±4.6 |
| Gray Soil    | Range 9.0±29.9 | 8.2±18.2 | Range 7.3±13.0 | 9.6±13.1 |
|              | Average 13.4±4.0 | 12.9±5.0 | Average 10.9±3.1 | 11.2±1.8 |

**Evaluation of the Content of Pb**

Lead is one of the heavy metals with very high toxicity to humans and animals. Lead can inhibit or mimic the actions of calcium and interact with proteins. Lead is incorporated into the mineral in place of calcium within the skeleton. Binding of biological lead and molecules could form and thereby interfering with their function by several mechanisms. Sulphydryl and amide groups of enzymes bind with this metal, altering their configuration and diminishing their activities. Lead may also compete with essential metallic cations for binding sites, inhibiting enzyme activity, or changing the transport of essential cations such as calcium. Lead intoxication induces cellular damage mediated by the formation of reactive oxygen species (ROS) that were demonstrated. Also, Jiun and Hsien reported that the levels of malondialdehyde (MDA) in blood strongly correlate with a lead concentration in the blood of exposed workers. This element affects the activities of antioxidant enzymes, including superoxide dismutase (SOD) glutathione peroxidase. The higher the lead content in the soil, the more ability to contaminate it on the biomass of vegetables. Therefore, the survey of lead content in soil is very significant. It helps managers to plan growing areas that are suitable for vegetables.

Table-4 presents the results of the analysis of Pb content in the surface layer and the deep layer in the dry season and the rainy season. When one looks at the statistics, one can see that there is a little bit of Pb in three types of soil in both seasons. The main reason is that farmers in this commune commonly use fertilizers including Pb, such as Song Danh organic fertilizer (23.2mg/kg), Kovac microbial fertilizer (17.6 mg/kg), NPK French (17 mg/kg), and Hanexim Ure (0.29 mg/kg). Besides, red soil samples that are distributed along Highway 20 may be contaminated with Pb from the exhaust fumes of vehicles passing through this highway (Pb was used to be mixed in gasoline to increase octane index before).

**Table-4: The Pb Content in Soil (mg/kg)**

| Type of Soil | Dry Season | Rainy Season |
|--------------|------------|--------------|
|              | Surface Layer | Deep Layer | Surface Layer | Deep Layer |
| Red Soil     | Range 23.7±32.1 | 21.1±27.1 | Range 17.3±24.3 | 16.6±26.0 |
|              | Average 26.8±3.9 | 24.5±2.8 | Average 21.2±2.2 | 22.6±3.1 |
| Yellow Soil  | Range 20.8±41.0 | 21.1±40.0 | Range 23.5±43.8 | 22.5±39.1 |
|              | Average 32.1±7.0 | 29.1±6.1 | Average 31.0±7.0 | 27.8±5.6 |
| Gray Soil    | Range 17.5±23.2 | 12.6±19.3 | Range 16.0±22.0 | 11.3±18.8 |

STUDY OF HEAVY METAL CONTENT

Quang Hieu Tran and Ngoc Tuan Nguyen

Fig.-6: The Content of Pb (mg/kg) in Different Types of Soil in the Dry Season

Fig.-7: The Content of Pb (mg/kg) in Different Types of Soil in the Rainy Season

From these Fig.-6 and 7, it is apparent that the contents of Pb in yellow-red soil in both seasons were the highest, followed by red basalt soil, ending with the lowest content of Pb in Gray soil. However, there is not much difference between the two seasons in the same soil layer. In comparison with the permitted level by the Ministry of Science and Technology of Vietnam (70 mg/kg) for the cultivated land, it can conclude that these Pb contents are safe for vegetables.

Evaluation of the Zn Content

Zinc is a non-toxic element to animals and humans, which is proved by the LD50 of the sulfate salts in rats. The oral LD50 for zinc is close to 3 g/kg body weight according to the Toxnet database of the U.S. National Library of Medicine. Besides, an important factor seems to be zinc homeostasis, allowing the efficient handling of an excess of orally ingested zinc, because, after intraperitoneal injection into mice, the LD50 for zinc was only approximately four-fold higher than for cadmium and mercury. The role of zinc in biology can be grouped into three general functional classes, namely catalytic, structural, and regulatory functions. Zinc content in soil is also an indicator to determine soil quality. If the zinc content is high, plants could easily absorb and grow well. In contrast, plants will grow poorly when the zinc level is low. The results of the analysis of Zn content is presented in Table-5, Fig.-8, and 9.

With red soil in the dry season, the Zn content of the surface layer fluctuates in the range of 62.2 mg/kg to 92.5 mg/kg; the average value is 80.8 mg/kg. At the bottom layer, the Zn content ranges from 47.6 to 82.5 mg/kg, an average of 61.2 mg/kg. This value in the rainy season was as follows: surface layer 63.8 to 84.4 mg/kg, an average of 74.0 mg/kg; in the deep layer, 49.3 to 83.5 mg/kg. Zinc is one of the essential trace elements for plants. The high Zn content proves that soil is suitable for many crops, including leafy vegetables and root crops. The zinc content of the red soil samples is the highest, followed by the red and yellow soil, the lowest in the gray soil. The results of this analysis also showed conformity with the regulations by the Vietnamese Ministry of Science and Technology for vegetable land.
Comparison of the Content of These Toxic Heavy Metals in Soil

Figure-10 compares the contents of Cd, Cu, Pb, Zn in the surface layer of cultivated land at Hiep An commune, Lamdong province, Vietnam. Overall, the Zn content in the Red soil is the highest, and the Cd content in the Gray soil is the lowest in both dry and rainy seasons. Some reasons can illuminate these: firstly, the nature of Red soil has the concentration of these metal more than others; secondly, this land has been used to cultivate. Thus a lot of fertilizers are used, resulting in the most accumulation of heavy metals. Therefore, some solutions proposed to protect these cultivated land are to plant a variety of vegetables that are suitable for different soils and to reduce the fertilizers, which are harmful to these areas.
STUDY OF HEAVY METAL CONTENT

Quang Hieu Tran and Ngoc Tuan Nguyen

Table-5: The Zn Content in Soil (mg/kg)

| Type of Soil | Dry season | Rainy Season |
|--------------|------------|--------------|
|              | Surface Layer | Deep Layer | Surface Layer | Deep Layer |
| Red Soil     | 62.2±92.5 | 47.6±82.5 | 63.8 ± 84.4 | 49.3 ± 83.5 |
| Yellow Soil  | 47.6±11.3 | 61.2±13.9 | 74.0 ± 7.7 | 59.8 ± 12.4 |
| Gray Soil    | 39.7±14.9 | 32.9±20.0 | 57.3 ± 12.9 | 53.0 ± 11.1 |

CONCLUSION

The content of heavy metal elements (Cd, Cu, Pb, and Zn) in 43 cultivated soil areas in two seasons has been surveyed to represent the three main types of soil in Hiep An Commune. The content of heavy metals in the soil is still within the allowable limits for vegetable land by the Ministry of Science and Technology of Vietnam. The Copper content in several samples of basalt is slightly higher than the permissible limit for growing vegetables that may be due to the use of copper-containing fertilizers. The Pb content in soil samples along National Highway 20 is higher than in uncultivated land and other types of property. The obtained results will be a useful reference for the authorities to assess and plan a safe vegetable development strategy for Lam Dong province in general and Hiep An in particular.
