Abstract—In this paper, we investigate the generalized degrees-of-freedom (GDoF) of the asymmetric interference channel with delayed channel state information at the transmitter (CSIT), where each transmitter has two antennas, each receiver has one antenna, and the strength for each interfering link can vary. The optimal sum-GDoF is characterized by matched converse and achievability proof. Through our results, we also reveal that in our antenna setting, the symmetric GDoF lower bound in [Mohanty et. al, TIT 2019] can be elevated, and the symmetric GDoF upper bound in [Mohanty et. al, TIT 2019] is tight in fact.

Index Terms—Delayed CSIT, sum-GDoF, interference channel.

I. INTRODUCTION

The degrees-of-freedom (DoF) characterization with delayed channel state information at the transmitter (CSIT) has attracted a plenty of research interests in the past decade. For example, the DoF region of multiple-input multiple-output (MIMO) interference channel with delayed CSIT was derived in [1]. The study of DoF of MIMO broadcast channel with delayed CSIT can be found in [2]–[5], whose exact value was still not completely obtained. The linear DoF region of MIMO X channel with delayed CSIT was characterized in [6].

One limitation of DoF is that the strength of each link is assumed to be equal, whereas the link strength can vary tremendously in wireless. Nevertheless, the generalized degrees-of-freedom (GDoF) overcomes this drawback by considering the different strength of each link, which was first proposed in [7]. The GDoF characterization with delayed CSIT can be found in [8]–[11]. In [8], the GDoF was studied in the two-user multiple-input single-output (MISO) broadcast channel under alternating delayed, perfect, and no CSIT, where sum-GDoF upper and lower bounds were shown to be partially coincided. In [9], the secure GDoF was investigated in the two-user MISO broadcast channel with an external eavesdropper and alternating delayed, perfect, and no CSIT. The GDoF region of the MIMO Z channel with delayed CSIT was characterized in [10]. For MIMO interference channel with delayed CSIT and symmetric interfering link strengths, symmetric GDoF upper and lower bounds were derived in [11], where the symmetric GDoF was characterized partially, and the upper and lower bounds do not change with antenna ratio, i.e., number of antenna at each transmitter over number of antennas at each receiver, if the antenna ratio is equal to or larger than two.

In this paper, we study the GDoF of the asymmetric interference channel with delayed CSIT, where the transmitter has two antennas, the receiver has one antenna, and the strength for each interfering link can vary. We characterize the sum-GDoF by presenting matched converse and achievability proof. Then, via this result, we reveal that in our antenna setting, the symmetric GDoF lower bound in [11] can be elevated, and the symmetric GDoF upper bound in [11] is tight in fact. The idea of elevating the GDoF lower bound comes from [9], where the authors in [9] fully exploit the receiver signal space by sending new fresh symbols in each time slot. Our transmission scheme generalizes the scheme in [9] Appendix C], which was designed for achieving the corner points of GDoF region of MISO broadcast channel with delayed CSIT.

II. SYSTEM MODEL

The considered asymmetric interference channel has two transmitters, denoted by Tx₁ and Tx₂, each with two antennas, and two receivers, denoted by Rx₁ and Rx₂, each with one antenna, as depicted in Fig. 1. The transmitter Txₐ, i = 1, 2, sends private message Wᵢ to the receiver Rxᵢ. The received signals at two receivers and time slot t can be written as

\[ y₁[t] = \sqrt{\rho_{h₁₁}[t]}x₁[t] + \sqrt{\rho_{h₂₁}[t]}x₂[t] + n₁[t], \quad (1a) \]
\[ y₂[t] = \sqrt{\rho_{h₁₂}[t]}x₁[t] + \sqrt{\rho_{h₂₂}[t]}x₂[t] + n₂[t], \quad (1b) \]

¹A representative antenna setting for this antenna configuration case is that the transmitter has 2 antennas and the receiver has 1 antenna.
where $x_j[t] \in \mathbb{C}^{2 \times 1}$ denotes the transmitted signal from transmitter $T_j$, at time slot $t$, $y_j[t] \in \mathbb{C}^1$, $j = 1, 2$, denotes the received signal at receiver $R_j$, and time slot $t$, $h_{ij} \in \mathbb{C}^{1 \times 2}$ denotes the channel matrix from transmitter $T_j$ to receiver $R_j$. $n_j \sim \mathcal{CN}(0, \sigma^2)$ denotes the additive white Gaussian noise (AWGN) at receiver $R_j$. The channel gains of desired links and interfering links are denoted by $\hat{h}^\perp$ and $\hat{h}^\parallel$, respectively. Without loss of generality, we assume that $\alpha_2 \leq \alpha_1$. The transmit signals follow an average power constraint, given by $\frac{1}{n} \sum^n_{i=1} \text{tr} \left( \mathbb{E}[x_i[t]x_i^H[t]] \right) \leq 1$. All entries of channel matrices are independent and identically distributed (i.i.d.) across space and time slot. The signal-to-noise ratio (SNR) at each receiver is $\rho$, and interference-to-noise ratio (INR) at receivers $R_1$ and $R_2$ are $\rho^{\alpha_2}$ and $\rho^{\alpha_1}$, respectively. We define the following assembly of channel matrices: $\hat{H}[t] \triangleq \{h_{ij}[t]\}_{i,j=1,2}$, and $H^\perp \triangleq \{H[t]\}_{t=1}^n$.

Due to feedback delay, the transmitter has delayed channel state information. Specifically, at time slot $t$, the transmitters know $H^\perp$, namely all the channel matrices up to time slot $t-1$. Two receivers have instantaneous knowledge of channel matrices. The encoding function at transmitter $T_j$ and time slot $t$ is denoted by $\tilde{g}_j(t)$. The decoding function at receiver $R_j$, after $n$ time slots is denoted by $\tilde{c}_{jn}(W_t, H^\perp)$.

The rate tuple is written as $(R_1(\rho, \alpha_1, \alpha_2), R_2(\rho, \alpha_1, \alpha_2))$, where $R_i = \frac{\log \mathcal{C}_i}{\log \rho}$ is the cardinality of message set $W_i$. The rate is achievable, if there exists a sequence of codebook pairs $(C_i, \tilde{C}_i)_{t=1}^T$ and decoding functions $\{c_{jn}, \tilde{c}_{jn}\}$ such that the error probability $P_e$ goes to zero when $n$ goes to infinity. The sum-capacity is defined as the supremum of sum of achievable rates, i.e., $C_{\text{sum}} = \sup \sum_{t=1}^T R_i(\rho, \alpha_1, \alpha_2)$. Then, the sum-GDoF is defined as the pre-log factor of sum-capacity, i.e., $\sum_{t=1}^T d_t = \lim_{\rho \rightarrow \infty} \frac{C_{\text{sum}}}{\log \rho}$.

III. MAIN RESULTS AND DISCUSSION

Theorem 1: For the considered asymmetric interference channel with delayed CSIT, defined in Section-II, the sum-GDoF is given as

$$\sum_{i=1}^2 d_i = \begin{cases} 2 - \frac{\alpha_1 + \alpha_2}{3}, & \alpha_1, \alpha_2 \leq 1, \\ \min \left\{ \frac{4 + \alpha_1 - \alpha_2}{3}, 2 \right\}, & 1 < \alpha_1 \leq \alpha_2 \leq 1 \\ \min \left\{ \frac{2 + \alpha_1 + \alpha_2}{3}, 2 \right\}, & 1 < \alpha_1, \alpha_2. \end{cases}$$

Proof: Please refer to Section-IV for the converse proof and Section-V for the achievability proof.

Remark 1: This sum-GDoF in (2) degenerates to optimal sum-GDoF in [11] by setting $\alpha_1 = \alpha_2 = 1$, whose value is the celebrated 4/3. Furthermore, in our antenna setting, it can be verified that the symmetric GDoF upper bound in [11] is tight.

IV. CONVERSE PROOF OF THEOREM 1

The key steps of this proof follows the that in [11]. To begin with, we define the following virtual received signals, which are obtained from removing the impact of $x_1[t]$ in the received signals at each receiver:

$$\begin{align*}
\gamma_1[t] &= \sqrt{\rho^{12}} h_{12}[t] x_2[t] + n_1[t], \\
\gamma_2[t] &= \sqrt{\rho^{12}} h_{22}[t] x_1[t] + n_2[t].
\end{align*}$$

Before the next step, we define the following assembly of channel matrices: $\tilde{H}^\perp \triangleq \{\tilde{h}_{ij}[t]\}_{t=1}^T$, $\tilde{H}^\parallel \triangleq \{\tilde{y}_i[t]\}_{t=1}^T$, and $\tilde{H}^\perp \triangleq \{\tilde{x}_i[t]\}_{t=1}^T$, $i = 1, 2$. Since the error probability $P_e$ goes to zero as $n$ goes to infinity, we denote $n_{\epsilon_n} \triangleq 1 + n R_i P_e(n)$ so that $\lim_{n \rightarrow \infty} \epsilon_n = 0$. According to [11], the rate of receiver 1 can be bounded as

$$n(R_1 - \epsilon_n) \leq \sum_{t=1}^n h(\tilde{y}_1[t]|\tilde{H}(t)) - \sum_{t=1}^n h(\tilde{y}_1[t]|\tilde{U}(t), \tilde{H}(t)), \quad (4)$$

where $\tilde{U}(t) \triangleq \{\tilde{y}_1^{-1}, \tilde{y}_2^{-1}, \tilde{H}^{-1}\}$. Next, according to [11], the rate of receiver 2 can be bounded as

$$n(R_2 - \epsilon_n) \leq \sum_{t=1}^n h(\tilde{y}_2[t]|\tilde{y}_1[t]|\tilde{U}(t), \tilde{H}(t)). \quad (5)$$

Henceforth, we define $S[t] \triangleq \{\sqrt{\rho^{12}} h_{12}[t], \sqrt{\rho^{22}} h_{22}[t]\}^T$, $K[t] \triangleq \mathbb{E}[x_2[t]x_2^H[t]|\tilde{U}(t)]$, $L[t] \triangleq \mathbb{E}[x_1[t]x_1^H[t]|\tilde{H}^{-1}]$, $V[t] \triangleq \{\tilde{U}(t), \tilde{H}(t)\}$, where the transmit covariance matrix $K[t]$ is independent of $h_{12}[t], h_{22}[t]$, and $S[t]$. Applying the extremal inequality in [12] for the physically degraded channel $\tilde{H}_2 \rightarrow (\tilde{y}_1, \tilde{y}_2) \rightarrow \tilde{Y}_1$, we have the following inequality:

$$\frac{2}{\mathbb{E} \left\{ \log \mathbb{E} [I_2 + S[t]K[t]S[t]^H] \right\}} \leq \max_{K[t]} \mathbb{E} \left\{ \log \mathbb{E} \left[ I_2 + S[t]K[t]S[t]^H \right] \right\}.$$ 

To proceed, we can approximate the first term of (6) as

$$\log \mathbb{E} \left[ I_2 + S[t]K[t]S[t]^H \right] \\
\overset{(a)}{=} \log \mathbb{E} \left[ I_2 + \left[ \sqrt{\rho^{12}} h_{12}[t] \right]^H \left[ \sqrt{\rho^{12}} h_{12}[t] \right] \right] \\
\overset{(b)}{=} \log \left[ I_2 - k_t + \rho^{12} h_{12}[t]^H h_{12}[t] + \rho h_{22}[t]^H h_{22}[t] \right] \\
\overset{(c)}{=} f(2 - k_t, 1, 1, 1) \log \rho + O(1) \\
= \begin{cases} \\
\min \left\{ 2 - k_t, 1 \right\} + \\
\min \left\{ \left[ 1 - k_t \right]^+, 1 \right\} \alpha_2 \log \rho + O(1), & \alpha_2 \leq 1, \\
\min \left\{ \left[ 2 - k_t \right]^+, 1 \right\} \alpha_2 + \\
\min \left\{ \left[ 1 - k_t \right]^+, 1 \right\} \log \rho + O(1), & 1 < \alpha_2. 
\end{cases} \quad (7)$$

where (a) is from SVD of $K[t]$, i.e., $K[t] = U[t]\Sigma[t]U[t]^H$ with unitary matrix $U[t] \in \mathbb{C}^{2 \times (2-k_t)}$ and diagonal matrix $\Sigma[t] \in \mathbb{C}^{(2-k_t) \times (2-k_t)}$, and $h_{ij}[t] = h_{ij}[t]|\Sigma[t]|^{1/2}$, where $k_t \in \{0, 1, 2\}$ denotes the number of zero singular values; (b) is from $|I + AB| = |I + BA|$; (c) is from [11] Lemma 1. The second term of (6) can be approximated as

$$\log \left[ 1 + \rho^{12} h_{12}[t]|K[t]|h_{12}[t]^H \right] \\
\overset{(a)}{=} \min \left\{ 2 - k_t, 1 \right\} \alpha_2 \log \rho + O(1), \quad (8)$$
where (a) is from SVD of $K[t]$ and [11] Lemma 1. Next, we can approximate the first term of (4) as
\[
h(y[t] | H[t]) \leq \log |1 + \rho h_{11}[t] L[t] h_{11}[t]^H + \rho^\alpha h_{12}[t] K[t] h_{12}[t]^H|
\]
(a) \leq \log \left( 1 + \rho h_{11}[t] L[t] h_{11}[t]^H + \rho^\alpha h_{12}[t] K[t] h_{12}[t]^H \right)
\]
(b) \leq \log \left( 1 + \rho h_{11}[t] L[t] h_{11}[t]^H + \rho^\alpha h_{12}[t] K[t] h_{12}[t]^H \right)
\]
(c) = \frac{f(1, (1, 2) \alpha_2, 2 - k_i)}{\log \rho + O(1)}, \quad \alpha_2 \leq 1,
\]
where \( \alpha \) is from Gaussian input maximizing the entropy with covariance constraints; (b) is from \( L[t] \preceq I_2 \) for \( \text{tr} \{ L[t] \} \leq 1 \) and the SVD of \( K[t] \); and (c) is from \[11\] Lemma 1.

As such, the upper bound of weighted sum of achievable rates from (4) and (5) is given in (10), shown on the top of next page, where (a) is from (4), (5) and (9); (b) is from (7) and (8); (c) is from maximizer is \( k_i = 0 \) by exhausting \( k_i \in \{0, 1, 2\} \). Then, we rewire (10) into GDoF expression,
\[
d_1(\alpha_1, \alpha_2) + d_2(\alpha_1, \alpha_2) = \frac{3 - \alpha_2}{2} \leq 1, \quad \alpha_2 \leq 1,
\]
Due to the symmetry, we have another GDoF inequality, i.e.,
\[
d_2(\alpha_1, \alpha_2) + d_2(\alpha_1, \alpha_2) = \frac{3 - \alpha_1}{2} \leq 1, \quad \alpha_1 \leq 1,
\]
Moreover, considering single-user GDoF bound for MIMO point-to-point channel, we have
\[
d_i(\alpha_1, \alpha_2) \leq 1, \quad i = 1, 2.
\]
Combing (11) with (12) and (13), we derive the sum-GDoF upper bound in Theorem 1 (see (12)). This ends the proof.

V. ACHIEVABILITY PROOF OF THEOREM 1

A. Proposed Transmission Scheme for \( 1 < \alpha_1, \alpha_2 \) and \( 1 < \alpha_1 \& 2 \leq \alpha_1 + 2 \alpha_2 \) Cases

The proposed transmission scheme is with block-Markov structure, and has \( B \) blocks with \( s \) time slot each block. Without loss of generality, we assume \( s = 1 \).

In the \( t \)th \( (1 \leq b < B) \) block, the transmitter \( T_x \) encodes the message \( w_i[b] \) desired by receiver \( R_x \), using the vector \( u_i(w_i[b]) \in \mathbb{C}^{2 \times 1} \), such that \( u_i \sim \mathcal{CN}(0, \rho^{-A_i} I_2) \) with \( 0 \leq A_i \leq \hat{A}_i \). The common message \( l_i[b-1] \) is encoded using the vector \( x_{ic}(l_i[b-1]) \in \mathbb{C}^{2 \times 1} \), which is transmitted at transmitter \( T_x \), with power \( O(\rho^\hat{A}_i) \). The transmit signal at block \( b \) and transmitter \( T_x \) can be written as follows:
\[
x_i[b] = u_i(w_i[b]) + x_{ic}(l_i[b-1]), \quad \sigma(\rho^{-A_i}) \quad \sigma(\rho)^0
\]
where \( i = 1, 2 \). The received signal at block \( b \) and receiver \( R_x \) is given as follows:
\[
y_i[b] = \sqrt{\rho} h_{ii}[b] x_{ic}(l_i[b-1]) + \sqrt{\rho^\alpha} h_{ij}[b] x_{jc}(l_j[b-1]) + \sqrt{\rho^{\alpha_2}} h_{ik}[b] u_i(w_i[b]) + n_i[b], \quad (15)
\]
where \( i \neq j \), and \( n_i[b] \) denotes the interference at receiver \( R_x \), which can be reconstructed at block \( b + 1 \). From the rate distortion theorem [13], this interference \( n_i[b] \) can be quantized using a source codebook with size \( O(\rho^{\alpha_j - \hat{A}_j}) \), such that the average distortion does not exceed the noise power level and can be ignored in GDoF analysis. The quantization index of interference \( n_i[b] \) is denoted by \( l_j[b] \), which is transmitted as \( x_{jc}(l_j[b]) \) from transmitter \( T_x \) in block \( b + 1 \). In the \( B^{th} \) block, the transmitter \( T_x \) sends common messages only, namely
\[
x_i[B] = x_{ic}(l_i[B-1]), \quad \sigma(\rho)^0
\]
where \( i = 1, 2 \). The received signal at block \( B \) and receiver \( R_x \) is given as follows:
\[
y_i[B] = \sqrt{\rho} h_{ii}[B] x_{ic}(l_i[B-1]) + \sqrt{\rho^\alpha} h_{ij}[B] x_{jc}(l_j[B-1]) + n_i[B], \quad (17)
\]
where \( i = 1, 2 \). The decoding procedure is backward and begins with block \( B \), where the common messages are firstly decoded. After that, at the \( (B - 1)^{th} \) block, the interference from transmitter \( T_x \) can be canceled and extra information about \( u_i(w_i[B-1]) \) can be provided. Generally, the equivalent channel for decoding can be written as follows:
\[
[\begin{array}{c}
y_i[b] - n_i[b] \\
0
\end{array}] = \begin{bmatrix}
\sqrt{\rho} h_{ii}[b] & x_{ic}(l_i[b-1]) \\
\sqrt{\rho^\alpha} h_{ij}[b] & 0
\end{bmatrix} + \begin{bmatrix}
\sqrt{\rho} h_{ii}[b] \\
\sqrt{\rho^\alpha} h_{ij}[b]
\end{bmatrix} u_i(w_i[b]) + \begin{bmatrix}
n_i[b] \\
0
\end{bmatrix}, \quad (18)
\]
where \( i, j = 1, 2 \) and \( i \neq j \). Note that (18) is equivalent to the three-user multiple-access channel (MAC). Applying capacity region of three-user MAC, we have the following general condition for achievable GDoF tuple to our problem:

**Proposition 1:** For the GDoF tuple \( (d_{11}, d_{12}, 1, d_{21}, d_{22}, d) \), which denote the GDoF carried in \( x_{2c}(l_2[b-1]), x_{ic}(l_1[b-1]), \)
\[ n \left( R_1 + \frac{R_2}{2} - e_n \right) \leq \sum_{i=1}^{n} f(N_i, (1, M), (\alpha_2, M - k_1)) \log \rho + \frac{1}{2} \sum_{i=1}^{n} h(\gamma_{1[i]} t_i, \gamma_{2[i]} t_i) + nO(1) \]

\[
\begin{aligned}
(\sigma) & \leq \sum_{i=1}^{n}((1 + \min\{2 - k_t, 1\}/2 + \min\{1-k_t^+, 1\})\alpha_2/2 - \min\{2 - k_t, 1\}\alpha_2) \log \rho + O(1), & \alpha \leq 1, \\
(\tau) & \leq \sum_{i=1}^{n}((\min\{1 - (2 - k_t)\}^+, 2)) + \min\{2 - k_t, 1\}\alpha_2/2 + \min\{1-k_t^+, 1\}/2) \log \rho + O(1), & 1 < \alpha_2.
\end{aligned}
\]

Therefore, we are able to formulate the following sum-GDoF lower bound maximization problem:

\[
\max_{A_1, A_2} \min\{A_1 + A_2, \alpha_1 + \alpha_2 + 2 - 2(A_1 + A_2), 2)} \tag{40}
\]

where the maximizer is \(A_1^* + A_2^* = \min\{(2 + \alpha_1 + \alpha_2)/3, 2\}. This leads to the sum-GDoF lower bound \( \min\{(2 + \alpha_1 + \alpha_2)/3, 2\} \) achievable.

2) \(1 < \alpha_1 \text{ and } \alpha_2 < 1 \text{ and } 2 \leq \alpha_1 + 2\alpha_2 \) Case: According to Proposition 1, we present the achievable GDoF condition in this case as follows:

\[
0 \leq A_2, \quad \alpha_1 - A_1 \leq 1, \tag{41}
\]

\[
d_1 \leq \alpha_1 + 1 - 2A_1, \tag{42}
\]

\[
d_2 \leq \alpha_2 + 1 - 2A_2, \tag{43}
\]

\[
\alpha_1 + \alpha_2 \leq 1 + A_1 + A_2, \tag{44}
\]

\[
d_1 \leq \left\{ \begin{array}{l}
\alpha_1 - A_1 + A_2, \quad 1 - A_1 \leq \alpha_2,
\alpha_1 - \alpha_2 + A_2 + 1 - 2A_1, \quad 1 - A_1 > \alpha_2,
\end{array} \right. \tag{45}
\]

\[
d_2 \leq \alpha_2 - A_2 + A_1, \tag{46}
\]

\[
d_1 \leq 1, \quad \alpha_1 - A_1 \quad \leq 1, \tag{47}
\]

\[
d_2 \leq 1, \tag{48}
\]

\[
d_1 \leq A_2 - \alpha_2 + 1, \tag{49}
\]

\[
d_2 \leq A_1. \tag{50}
\]

Therefore, due to \(2 \leq \alpha_1 + 2\alpha_2\), we are able to formulate the following sum-GDoF lower bound maximization problem:

\[
\max_{A_1, A_2} \min\{A_1 + A_2 - \alpha_2 + 1, \alpha_1 + \alpha_2 + 2 - 2(A_1 + A_2) \}. \tag{51}
\]

where the maximizer is \(A_1^* + A_2^* = (\alpha_1 + 2\alpha_2 + 1)/3\). This leads to the sum-GDoF lower bound \((4 + \alpha_1 - \alpha_2)/3\) achievable.

### B. Proposed Transmission Scheme for \(\alpha_1, \alpha_2 \leq 1 \) Case

In the 1st time slot, the transmitter \(T_1\) sends three symbols for receiver \(R_1\) and transmitter \(T_2\) sends one symbol for receiver \(R_2\). Let us denote the symbols desired by receiver \(R_1\) transmitted in time slot 1 by \(a_1, a_2, a_3\), and denote the symbol desired by receiver \(R_2\) transmitted in time slot 1 by \(b_1\). The transmit signal at transmitter \(T_1\) is designed as

\[
x_{11} = a_1 a_2^{-\alpha_1/2} \phi. \tag{52}
\]
The transmit signal at transmitter Tx2 is designed as

$$x_2[1] = \begin{bmatrix} b_1 \rho^{-\alpha_1/2} \end{bmatrix}.$$  \hfill (53)

As such, the received signals at each receiver are expressed as

$$y_1[1] = \sqrt{\rho} h_{11}[1] \begin{bmatrix} a_1 \alpha_2 \end{bmatrix} + \sqrt{\rho} h_{11}[1] \begin{bmatrix} a_2 \sum \alpha_1 \end{bmatrix} \begin{bmatrix} a_3 \rho^{-\alpha_1/2} \end{bmatrix}$$

$$+ \sqrt{\rho} h_{12}[1] \begin{bmatrix} b_1 \rho^{-\alpha_1/2} \end{bmatrix},$$  \hfill (54a)

$$y_2[1] = \sqrt{\rho} h_{21}[1] \begin{bmatrix} a_1 \alpha_2 \end{bmatrix} + \sqrt{\rho} h_{21}[1] \begin{bmatrix} a_2 \sum \alpha_1 \end{bmatrix} \begin{bmatrix} a_3 \rho^{-\alpha_1/2} \end{bmatrix}$$

$$+ \sqrt{\rho} h_{22}[1] \begin{bmatrix} b_1 \rho^{-\alpha_1/2} \end{bmatrix}.$$  \hfill (54b)

It can be seen that a part of interference fall into noise level. Moreover, each receiver can retrieve the profile of $O(\rho^{\alpha_2})$ part and decode the information of $O(\rho^{1-\alpha_2})$ part immediately.

In the 2nd time slot, the transmitter Tx2 sends three symbols for receiver Rx2 and transmitter Tx1 sends three symbols for receiver Rx1. Let us denote the symbols desired by receiver Rx2 transmitted in time slot 2 by $b_2, b_3, b_4$, and denote the symbol desired by receiver Rx1 transmitted in time slot 2 by $a_4$. The transmit signal at transmitter Tx1 is designed as

$$x_1[2] = \begin{bmatrix} a_4 \rho^{-\alpha_2/2} \end{bmatrix}.$$  \hfill (55)

The transmit signal at transmitter Tx2 is designed as

$$x_2[2] = \begin{bmatrix} b_2 \\ b_3 \end{bmatrix}.$$  \hfill (56)

As such, the received signals at each receiver are expressed as

$$y_1[2] = \sqrt{\rho} h_{11}[2] \begin{bmatrix} a_4 \rho^{-\alpha_2/2} \end{bmatrix} + \sqrt{\rho} h_{12}[2] \begin{bmatrix} b_2 \\ b_3 \end{bmatrix}$$

$$+ \sqrt{\rho} h_{12}[2] \begin{bmatrix} b_4 \rho^{-\alpha_2/2} \end{bmatrix},$$  \hfill (57a)

$$y_2[2] = \sqrt{\rho} h_{21}[2] \begin{bmatrix} a_4 \rho^{-\alpha_2/2} \end{bmatrix} + \sqrt{\rho} h_{22}[2] \begin{bmatrix} b_2 \\ b_3 \end{bmatrix}$$

$$+ \sqrt{\rho} h_{22}[2] \begin{bmatrix} b_4 \rho^{-\alpha_2/2} \end{bmatrix}.$$  \hfill (57b)

The achievable sum-GDoF is calculated as follows:

$$y_1[3] = \sqrt{\rho} h_{11}[3] \begin{bmatrix} c_1 \\ \phi \end{bmatrix} + \sqrt{\rho} h_{12}[3] \begin{bmatrix} a_5 \rho^{-\alpha_2/2} \end{bmatrix}$$

$$+ \sqrt{\rho} h_{12}[3] \begin{bmatrix} c_2 \\ \phi \end{bmatrix} + \sqrt{\rho} h_{12}[3] \begin{bmatrix} b_5 \rho^{-\alpha_2/2} \end{bmatrix},$$  \hfill (58a)

$$y_2[3] = \sqrt{\rho} h_{21}[3] \begin{bmatrix} c_1 \\ \phi \end{bmatrix} + \sqrt{\rho} h_{21}[3] \begin{bmatrix} a_5 \rho^{-\alpha_2/2} \end{bmatrix}$$

$$+ \sqrt{\rho} h_{21}[3] \begin{bmatrix} c_2 \\ \phi \end{bmatrix} + \sqrt{\rho} h_{21}[3] \begin{bmatrix} b_5 \rho^{-\alpha_2/2} \end{bmatrix},$$  \hfill (58b)

where $a_5, b_5$ are symbols desired by receivers Rx1 and Rx2, respectively.

VI. CONCLUSION

The sum-GDoF was characterized in the asymmetry interference channel with delayed CSIT, where each transmitter has 2 antennas and each receiver has 1 antenna. In the future, it is interesting to design a better transmission scheme in $1 < \alpha_1 & \alpha_2 < 1 \& \alpha_1 + 2\alpha_2 < 2$ Case.
