This paper will appear in the preprints for the third International
Joint Conference on Artificial Intelligence (IJCAI-73). This research
was supported in part by Research Grant MH-07732 from the National
Institutes of Health and in part by the Advanced Research Projects
Agency of the Office of the Secretary of Defense (F44620-70-C-0107)
which is monitored by the Air Force Office of Scientific Research.
PAS-II: AN INTERACTIVE TASK-FREE VERSION OF
AN AUTOMATIC PROTOCOL ANALYSIS SYSTEM

D. A. Waterman and A. Newell

Departments of Psychology and Computer Science
Carnegie-Mellon University
Pittsburgh, Pennsylvania

Abstract

PAS-II, a computer program which represents a
generalized version of an automatic protocol system
(PAS-I) is described. PAS-II is a task-free, inter-
aactive, modular data analysis system for inferring
the information processes used by a human from his
verbal behavior while solving a problem. The output
of the program is a Problem Behavior Graph: a descrip-
tion of the subject's changing knowledge state during
problem solving. As an example of system operation
the PAS-II analysis of a short cryptarithmetic pro-
ocol is presented.

1. Introduction

Automatic protocol analysis is a joint effort
by man and machine to infer from the record of the
time course of a subject's behavior, the underlying
information processes. As developed (5), it usually
refers to the verbalizations of a subject solving
some problem under instructions to think out loud.
Protocol analysis designates the full range of activ-
ities engaged in by the psychologist when working
with protocols: description of the subject's
behavior according to an hypothesized model, in-
duction of new rules, derivation of consequences from
a model in the context of specific data, and measure-
ment of adequacy of a model. The initial focus of
our work has been behavior description in terms of
information processes, given an hypothesized general
model (the so-called problem space in which the
subject operates).

The PAS-I system (14, 15) was our first attempt
at automatic protocol analysis. This is a fully
automatic, non-interactive, specialized system de-
digned to analyze cryptarithmetic protocols and pro-
duce an output a problem behavior graph (PBG) describ-
ing the subject's search through a posited problem
space. The protocol analysis is represented as a
sequence of processing stages that eventually trans-
form the raw protocol into a problem behavior graph.
At each stage rules are applied which effect a trans-
formation of the data. The organization of PAS-I is
shown in Figure 1.

PAS-I has successfully analyzed protocols from
DONALD+GERALD=ROBERT and CROSS+ROADS=DANGER crypt-
arithmetic problems. The results obtained in the
DONALD+GERALD=ROBERT task for two of the subjects
have been discussed in detail (15) and demonstrate
that this approach to automatic protocol analysis is
both feasible and rewarding.

Encouraged by the success of PAS-I we have
designed and built an improved version called PAS-II.
PAS-II was designed with two major goals in mind: to
make it interactive and task free. By interactive
we mean that the user is permitted to take an active
part in the analysis: he can provide answers to sub-
problems the system is unable to solve, correct proc-
essing errors, and even maintain control over the
processing sequence. Clearly, real-time interaction
of this sort makes the system a more powerful tool
for protocol analysis. By task free we mean that the
system is independent of any particular problem
domain. To make PAS-II task free we partitioned the
system into two parts: the problem dependent part
consisting of the processing rules or heuristics used
at each stage of the analysis, and the problem
independent part consisting of the general control
structure and command language. Thus, to apply the
system to a protocol in a new problem area the user
must first supply the system with processing rules
for that domain. The design of PAS-II also included
four subgoals: to make the system transparent,
modifiable, extendable, and open (see Figure 2).

Two important implementation issues were not
addressed in the design of PAS-II. 1). Improve system
performance in cryptarithmetic. This includes
expanding the deductive and inductive inference
capabilities, and "fine tuning" the system by
optimizing the processing heuristics to produce the
best possible analysis within the given framework.
2). Extend the scope of the analysis. For example,
extend the system back to handle the speech recogni-
tion and segmentation problems inherent in producing
a transcription from the audio tape. Or extend the
system to handle the problem of inducing the problem
space from the protocol or inducing a production
system model from the problem behavior graph.

It was decided to make PAS-II interactive and
task free, postponing the problems of increasing
power in a particular task or broadening the scope
of the analysis. This decision was influenced by
the desire to provide a working tool for protocol
analysis that could be used by participants at a
workshop on New Techniques in Cognitive Research held
at CMU in the summer of 1972 (7). The PAS-II system is
currently running in LISP at CMU on a PDP-10 and is
available to the CMU (and the ARPA Network) community.

This paper is organized as follows. The task of
protocol analysis is discussed in Section 2. This is
followed in Section 3 by a brief description of the
structure of the program and in Section 4 by an
example of its use in analyzing a cryptarithmetic
protocol. Section 5 concludes with a discussion of
the general executive structure of the system and
its implication for AI data analysis programs.

2. Task of Protocol Analysis

Protocol analysis is a complex data processing
task requiring both deductive and inductive inference
capabilities. Our current approach to protocol analy-
sis is based on a particular theory of human problem
solving. For a description of this theory and an
introduction to the task of protocol analysis see
Newell and Simon (5).

Ultimately, a library containing processing rules
for a number of different problem domains will be
available to the user.
GOALS
Interactive: User and system exchange information during processing.
Task Free: System is independent of any particular problem domain.

SUBGOALS
Transparent: System is easy to use and understand by virtue of a clean organization and the ability to explain itself.
Modifiable: Basic changes in the data processing procedure can be made by a user with no knowledge of the language used to program the system.
Extendable: The programmer can easily enlarge the system to encompass a wider range of the data analysis.
Open: The user, rather than the program, initiates and controls the interaction and accordingly gains ultimate control of the processing sequence.
The theoretical substructure

Problem Space. We assume human problem solving takes place by search in a problem space. The elements of this space are the possible states of knowledge the subject can have about the task, where a state of knowledge is simply an expression of what the subject knows at some particular point in the space. Besides knowledge states, the problem space also includes a set of operators. These define operations the subject can perform on knowledge at a particular state to yield new knowledge—hence to move to a new knowledge state. The operators are incremental, that is, they take as input a small portion of the total knowledge state (a small set of knowledge elements) and produce as output new knowledge elements.

Problem Behavior Graph. The subject’s search through the problem space for a solution can be described as a sequence of operator applications that create a string of incrementally changing knowledge states. The plot of this search is called the problem behavior graph (PBG). Figure 8 (also used to illustrate the output of the analysis given in section 4) shows a problem behavior graph for cryptarithmetic. The nodes represent operator applications: the knowledge elements at the lower left of each node are the inputs, those at the lower right are the outputs. PBG branching results from the subject abandoning information and returning to a prior knowledge state (usually because of a discovered contradiction). For example, in Figure 8 the outputs of nodes 4 and 6 conflict: "R is 4" conflicts with "R is odd," and leads to the abandonment of nodes 4, 5, and 6. Note that the knowledge state at any point in the graph is the conjunction of all output elements on the path from the given point back to the beginning of the graph. All nodes on the path from the last node back to the beginning of the graph are called currently active nodes. Their output elements define the current knowledge state.

Data Analysis

The data being analyzed is the transcribed text of a subject’s verbal protocol. As the text is transformed into a PBG it is subjected to four major types of processing: linguistic, semantic, group, and PBG. Figure 1 typifies such a processing sequence.

Linguistic Processing. The text is first segmented into shorter strings called topic segments, each of which is expected to ultimately yield approximately one problem space element. Each segment is then parsed using a grammar sensitive to the problem domain under consideration. The result of parsing is a set of semantic elements which represent the meaning of the segment. For example, the segment "D is not equal to 6" might yield the elements (NEG)(EQ D 6) in the cryptarithmetic task. Here (NEG) is called an indicator element, (EQ D 6) a knowledge element.

Semantic Processing. The semantic elements produced through parsing are first combined in very elementary ways to produce new elements, i.e., (NEG) and (EQ D 6) become (NEG D 6). Next, new elements reflecting relationships between elements from adjacent segments are produced. Thus, (EQ D 5) from one segment and (THEREFORE)(EQ T 0) from the next segment become (BECAUSEOF (EQ D 5)(EQ T 0)), e.g., "because D is 5, T is 0." Finally, these elements are arranged into initial approximations of operator groups, each containing an operator element and the surrounding knowledge and indicator elements. An operator group is defined to be an operator together with its input and output knowledge elements.

Group Processing. The tentative operator groups produced during semantic processing are now analyzed to obtain a complete picture of what the subject knows at each moment and what operators he applies. First, variables in semantic elements are identified by comparing the elements to the current context as defined by the PBG. Thus if (EQ D 3) were in the PBG then when given the element (EQ <L> 5), where <L> stands for a class of letters, we recognize that <L> in this case is the letter D.

The second part of group processing consists of finding, or hypothesizing, the origin of every knowledge element in each tentative group. The origin of a knowledge element is defined to be the operator which produced it, plus the inputs to that operator, plus the operators which produced those inputs, etc. Thus the origin can be represented as a tree which defines a collection of overlapping operator groups.

PBG Processing. The operator groups produced during group processing are now incorporated into the PBG. In general, each group becomes a node in the PBG. In the simplest case the new node is just attached to the last currently active node. However, when contradictions occur (the output of one node conflicts with the output of another) restructuring occurs to eliminate the conflict (see Figure 8).

3. Structure of the Program

PAS-II takes as input a transcribed text of the verbalization of a subject solving a problem and produces as output a PBG. The processing rules for the various stages, including the rules defining the problem space, are given to the system. These rules are supplied either by the system builder via a library of rules for various problem domains or by the user himself.

Modular Structure

PAS-II is organized as a modular data analysis system. The basic unit of organization is the mode: a processing state which has associated with it a buffer capable of holding rules or data. This buffer can be modified by the editing functions available in the command language. There are three types of modes: run modes, which hold the data being analyzed, rule modes, which hold the processing rules, and auxiliary modes, which hold task-free system-oriented rules. Thus the information in the rule modes constitutes the problem dependent part of the system.

The next level of organization is the stage: a unit consisting of one run mode and any number of associated rule modes. Data processing is performed in a stage by applying the rules from the rule modes associated with that stage to the data present in the run mode of the previous stage. The result of the processing is then put into the run mode of the current stage. Figure 3 illustrates the modular organization of PAS-II, with the arrows indicating data flow and the lines indicating mode associations.

The highest level of organization is the processor: a unit consisting of consecutive stages in the control cycle. For example, in PAS-II two linguistic stages form the Linguistic processor and three semantic stages form the Semantic processor.
Figure 3. Modular organization of PAS-II (Auxiliary modes not shown)
The modes currently implemented in PAS-II are listed in Table 1. Note that most run modes have one or two rules associated with them. This association is illustrated in Table 1 and also in Figure 3, which shows the modular composition of the various processors in PAS-II. The arrows in the figure define the data links existing between modes. The mode at the tail of an arrow provides the data that the mode at the head of the arrow processes. For example, processing in the TOPIC mode involves applying the SEGMENTATION rules to the data in the TEXT mode and then placing the result in the TOPIC mode. As each line in TEXT is processed, it is deleted from the TEXT buffer. However, a copy of these deleted lines is stored elsewhere in TEXT and can be retrieved (see the process functions in Table 2). The arrows in Figure 3 do not necessarily define the control cycle, i.e., the order in which processing occurs. The control flow is illustrated in Figure 4 (to be discussed later).

| MODES |
|-------|
| RUN | RULE | AUXILIARY |
|---|---|---|
| TEXT | SEGMENTATION | ASSOCIATION |
| TOPIC | SPACE, GRAMMAR | SAVE |
| LINGUISTIC | EXTRACTION | CONTROL |
| LINGUISTIC | INTEGRATION | INFORMATION |
| SEMANTIC | NORMALIZATION | |
| SEMANTIC | GROUPING | |
| GRAPHIC | ORIGIN | |
| GRAPHIC | CONFLICT, PBG | |
| TRACE | PS, MEMORY | |
| TRACE | MATCH | |

Table 1. PAS-II Modes.

Functions. The functions currently implemented in PAS-II are listed in Table 2. They constitute the command language available to the user, and are divided into four categories: basic, edit, flag, and process functions. Note that a mode name is a function that puts the user into that mode.

A function call consists of a function name followed by its arguments. Any number of function calls may occur together. If it is not clear which names are the functions and which are the arguments, parentheses can be used for disambiguation. In ambiguous cases the system always assumes the name is a function name rather than an argument. Thus if the user types HELP TOPIC DISPLAY 3 it could mean either (HELP TOPIC): give me information about the TOPIC mode, and (DISPLAY 3): display line 3 of the current buffer; or (HELP): tell me how to get help, (TOPIC): put me into the TOPIC mode, and (DISPLAY 3): display line 3. The system would make the latter interpretation.

Auxiliary Modes. There are four auxiliary modes: save, control, association, and information. The SAVE mode contains rules which specify which mode buffers are to be saved on (or read into) a disk file when the WRITE (or READ) command is executed. The CONTROL mode contains rules which define the control cycle for the system. Initially these rules define the control flow shown in Figures 3 and 4. The ASSOCIATION mode contains rules which define the associations between run and rule modes. The initial (or default) associations are those shown in Figure 3. The CONTROL and ASSOCIATION modes, together with the CREATE function, permit the sophisticated user to create new modes, redefine mode associations, and reorganize the control flow for the entire system. One example of this is the use of a reorganized PAS-II to analyze a problem description (problem text) in natural language in order to infer from that text a tentative problem space, one that a subject might use in representing the problem (2).

The INFORMATION mode is unique in containing no buffer and recognizing none of the functions that constitute the command language. Instead, this mode responds to key words in the user's input, which may be in sentence form. The mode provides the user with general information about PAS-II: its basic organization, purpose, and techniques of operation. This is to be contrasted with the HELP function, which provides the user with specific, on-the-spot information about the mode he is in.

Control Structure

The control cycle for PAS-II is shown in the flow diagram of Figure 4. The solid arrows indicate the stage that is entered once processing in the current stage is finished. The broken arrows indicate which stage to enter before processing is started. Processing in LINGUISTIC1, SEMANTIC3, and GRAPHIC2 is incremental. In each of these modes only part of the data from the previous mode is processed at one time. This initial portion of the data is then carried through the rest of the system, leading to the growth of PBG nodes, before the rest of the data in the previous mode is processed. This is done to establish a semantic context (the PBG) as early as possible in the processing sequence so it can provide feedback needed for linguistic, semantic, and group processing.

Since the control organization of PAS-II is quite flexible, the user is under no constraints to process the data in the order shown in Figure 4. He may skip or repeat stages within the existing control framework, and may redefine the control cycle (via the CONTROL mode). He may also have the system put him into the next run mode in the control loop, or even automatically step him through the run modes, initiating the processing at each stage (see NEXT and AUTOMATIC in Table 2).

Data Processing

Figures 3 and 4 show the processors which comprise the control cycle of PAS-II. In the Topic processor transcribed text is segmented into phrases containing only a single task topic. Then in the Linguistic processor an initial collection of these topics is formed. The TRANSLATION rules are applied to the phrases in the PBG to create a tentative problem space, and a semantic context (the PBG) is established. This is a slight extension: PAS-I requires segmented text as input.

* At present the PBG provides feedback for group processing only.
** This is a slight extension: PAS-I requires segmented text as input.
## FUNCTIONS

| NAME      | DESCRIPTION                                      |
|-----------|--------------------------------------------------|
| CREATE    | Creates a new mode.                             |
| DISPLAY   | Displays the contents of M.                     |
| ERASE     | Uncreates M (if it was formed using CREATE).    |
| EXIT      | Takes the user out of the system (to LISP).     |
| HELP      | Provides system information pertinent to M.     |
| MODE      | Tells the user what mode he is in.              |
| NEXT      | Puts the user into the next mode of C.          |
| RULE      | Puts the user into the rule mode associated with M. |
| RUN       | Puts the user into the run mode associated with M. |
| BREAK     | Breaks a line in M into two or more smaller lines. |
| CONNECT   | Connects adjacent lines in M to form a single line. |
| DEFINE    | Permits the user to define the contents of lines in M. |
| DELETE    | Deletes lines in M.                             |
| ED        | Enables the user to perform intra-line editing in M. |
| INSERT    | Inserts a line after a given line in M.         |
| READ      | Reads data from a disk file into M.             |
| RENUMBER  | Renumbers the lines in M.                       |
| WRITE     | Write the contents of M onto a disk file.       |
| AUTOMATIC | Steps the user through C, executing GO in each run mode. |
| BATCH     | Stops system queries during run mode processing.|
| COMMENT   | Permits comments to be displayed when a line is displayed. |
| FAST      | Speeds up reading from the disk by eliminating format checking. |
| HUSH      | Abbreviates error messages.                     |
| NUMBERS   | Causes disk files to be written with buffer line numbers. |
| PRINT     | Puts all the I/O at the terminal onto a disk file. |
| SEARCH    | Causes processing to be repeated until no rules are applicable. |
| SUPPRESS  | Suppresses printing of auxiliary information during processing. |
| TIME      | Causes processing time in M to be printed.      |
| VERSION1  | Causes the old version of grammar/parser to be used. |
| VERSION2  | Causes the new improved version of grammar/parser to be used. |
| AGAIN     | Puts the data in M into P and fires GO.          |
| COPY      | Prints the copy of the data in M.               |
| GO        | Processes the data located in P and puts the result into M. |
| RECOPY    | Puts the copy of the data from M back into M.    |
| RESTART   | Puts the copy of the data from P back into P and fires START. |
| START     | Deletes the data in M and fires GO.              |

**KEY**

- M: mode buffer of the mode the user is in
- P: mode buffer prior to M in C
- C: control cycle

Table 2. Description of PAS-II Functions
(Flag descriptions are for the condition flag = T)
Figure 4. Flow diagram of PAS II

Key: ——— stage to enter after processing
    ——— stage to enter before processing
segments is parsed yielding sets of semantic elements.
These elements are processed and refined in the
Semantic processor to produce groups composed of one
operator element and its associated input and output
knowledge elements. In the PBG processor these groups
are incorporated into the PBG. The Trace processor
is then used to compare this PBG with the trace
produced by a given production system model of the
subject.

Topic Processor. The Topic processor contains
two run modes: TEXT and TOPIC. TEXT is an initiali-
ization mode; it holds the data for TOPIC to process.
Thus no real processing takes place in it. The
TOPIC mode uses the SEGMENTATION rules to segment all
the text in the TEXT mode. These rules have the
general form: string / string, where a string is
any sequence of words, punctuation marks, or word
classes (as defined in the GRAMMAR mode), including
the null sequence. The slash (/) indicates where the
text is to be broken, i.e., after every occurrence
of string1 that is immediately followed by an occur-
rence of string2. Figure 6 shows SEGMENTATION rules
for cryptarithmetic (to be used in the example in
Section 4).

Linguistic Processor. The Linguistic processor
contains two run modes: LINGUISTIC1 and LINGUISTIC2.
In LINGUISTIC1 the EXTRACTION rules are used to select
a consecutive set of segments from TOPIC, representing
an initial guess as to the minimum number of segments
from which a group can be inferred. Processing con-
sists only of transferring these segments from the
TOPIC mode to the LINGUISTIC1 mode. At present, the
EXTRACTION rules are simply a single integer speci-
yfing how many segments to transfer.

Processing in LINGUISTIC2 mode consists of
applying the SPACE and GRAMMAR rules to all the topic
segments in LINGUISTIC1. The parsing operation pro-
duces, for each segment, a set of semantic elements
representing the meaning of the segment. The rules
in the SPACE mode define the problem space and have the form: **(semantic-element)** where a semantic
element is either an operator, knowledge, or indicator
element, and the type is either OP, KN, or IND. The
GRAMMAR rules define a key-word grammar and have the form:
<class> = (item1 ^ item2 ^ ...) (item, item2
...), where an item is either a class
denoted by angle brackets) or a literal (such as a
word, letter, or character). An asterisk (*) can be
used between any two items to indicate a match with
any string of text, and any GRAMMAR rule which is a
disjunction of single literals can be written without
parentheses. Figure 6 shows SPACE and GRAMMAR rules
for cryptarithmetic.

Semantic Processor. The Semantic processor
contains three run modes: SEMANTIC1, SEMANTIC2, and
SEMANTIC3. In SEMANTIC1 the INTEGRATION rules produce
new elements by combining semantic elements generated
from the same or adjacent segments. In SEMANTIC2 the
NORMALIZATION rules map knowledge and indicator ele-
ments into single elements reflecting the relationships
existing between two or more knowledge elements. In
SEMANTIC3 a tentative operator group (protogroup) is
formed. The INTEGRATION AND NORMALIZATION rules are
replacement rules of the type A => B, i.e., replace
A with B. Both A and B can be lists of semantic
elements. A slash (/) indicates that the next
elements of the list occur on the next line of the
mode buffer. Class names and X's are used as vari-
ables, and in the NORMALIZATION rules A's are vari-
ables which stand for knowledge elements on adjacent
lines connected by the AND indicator. Typical INTEGRATION and NORMALIZATION rules for crypt-
arithmetic are shown in Figure 6. GROUPING rules are
not shown. They define a protogroup to be the
largest consecutive sequence of elements containing
no more than one operator element.

Group Processor. There are two run modes in the
Group processor: GRAPHIC1, and GRAPHIC2. GRAPHIC1
processing fills in the values of variables in the
semantic elements by comparing the element containing
variables with all the elements currently active in
the PBG, i.e., the current context. When a match is
found the appropriate values are filled in. Currently
the UNKNOWNs rules are not accessible to the user.

Processing in GRAPHIC2 is a joint man-machine
Effort: the goal is to hypothesize for each know-
 ledge element its origin, i.e., the operator and its
inputs (and the operators that produced those inputs,
etc.) that produced that knowledge element as output.
The system queries the user asking for possible
operators and inputs that could have produced the
element whose origin is being sought. From this
information the system constructs an origin tree,
and hypothesizes which path through the tree repre-
sents the actual origin of the element. The path is
picked on the basis of the agreement between the
hypothesized inputs and the actual context defined by
the current PBG. The ORIGIN rules, like the GROUPING
and UNKNOWNs rules, are currently not accessible.

PBG Processor. The PBG processor contains one
run mode: GRAPHIC3. In the GRAPHIC3 mode, processing
consists of taking the operator groups produced in
GRAPHIC2 and incorporating them into the problem
behavior graph. The CONFLICT rules are used to deter-
mine whether or not any knowledge elements in the
operator groups conflict with knowledge already in the
PBG. If such a conflict occurs, the PBG rules are
used to restructure the PBG so the conflict is
eliminated.

SPACe rule 8 in Figure 6 is an exception. It
defines a set named <V> containing two members,
the class <LETTER> and the class <DIGIT>.

Two parsers are available, a simple top down
parser and a more sophisticated parser written
by M. Rychener.

At the current stage of development the Grouping
rules have not been made accessible to the user.

This is the major place where we have not regained
in PAS-II the power for automatic processing
available in PAS-I.
Both the CONFLICT and PBG rules are ordered production rules of the form \( S \rightarrow A \), i.e., in situation \( S \) take action \( A \) (12, 13). A situation is defined by a list of values of certain variables, called the state vector, \( SV \). The left side of each production rule has the form \( (V_1, V_2, V_3, \ldots) \), where \( V \) represents a permissible value for the \( n \)th state vector variable. The right side has the form \( (A_1, A_2, A_3, \ldots) \), where the \( A \)'s represent actions to be taken. The current values of the state vector variables are compared with the left side of each production rule. The first match, from top to bottom, determines the actions to be taken (an asterisk is considered to match any value).

Figure 6 shows CONFLICT and PBG rules for cryptarithmetic. The CONFLICT rules determine whether or not two given knowledge elements conflict. The example CONFLICT state contains: (SAMPLE 2), which is true (T) if the second items of both the elements are identical and false (F) otherwise; (ITEM 1 1), which returns as a value the first item of the first element (the element in the PBG); and (ITEM 1 2), which returns as a value the first item of the second element (the element in the group). Thus if the two elements being compared were \((\text{ODD R})\) and \((\text{NEQ R 5})\) CONFLICT rule 3 would match the state vector and the decision would be that no conflict exists.

The PBG rules determine the type of restructuring that occurs once a conflict is detected. The PBG state vector in Figure 6 has 2 variables: TYPE, which has the value CON if restructuring is based on cancellation and SIM if it is based on similarity; and (ITEM 1 2), which is defined above. The actions shown in Figure 6 are BLOCKREJ, a type of restructuring where blocks of adjacent nodes are abandoned, and COPY, a specification that the group causing the restructuring should remain in the active portion of the PBG after restructuring. The state vectors for CONFLICT and PBG may contain variables and actions other than the ones shown in Figure 6. For a complete description of these rules see the PAS-II reference manual (16).

Trace Processor. The Topic, Linguistic, Semantic, Group and PBG processors comprise the major portion of PAS-II. It is this portion which represents a generalized version of PAS-I. The Trace processor is a new extension to the system and has no analogue in PAS-I. Some parts of it, like the MATCH mode, are still under development. The Trace processor enables the user to write a production system model of the subject (6), and then compare the trace obtained by running the production system model with the PBG obtained by analyzing the protocol. The details are described elsewhere (16).

4. Example of Program Operation

To illustrate the use of PAS-II, we present a listing of the actual user-machine interaction involved in the on-line analysis of a short cryptarithmic protocol. The cryptarithmic task is given in Figure 3. Both the protocol and the cryptarithmic rules used for this example are shown in Figure 6. The protocol is stored in the TEXT mode and the cryptarithmetic rules in the eight rules modes shown. These rules approximate the minimal set needed to analyze the given protocol, and are for expository purposes only.

The annotated listing is shown below. The user input is in lower case and the system output in upper case. The system prompts the user by typing either an asterisk (*) or a question followed by a question mark (?).

*next go

D O N A L D D = 5
G E R A L D
R O B E R T

The above expression is a simple arithmetic sum in disguise. Each letter represents a digit, that is, 0, 1, 2, ..., 9. Each letter is a distinct digit. You are given that D represents the digit 5; thus, no other letter may be 5.

What digits should be assigned to the letters such that when the letters are replaced by their corresponding digits the above expression is a true arithmetic sum?

Figure 5. Cryptarithmetic Task
```

The user first entered the TEXT mode and displayed its contents. He then entered the next mode in the control cycle, TOPIC, and started processing by typing GO. This caused the SEGMENTATION rules to be applied to the data in TEXT. The system indicated that the data in line 1 of the previous mode had been transformed into the seven lines shown above, and asked if this transformation was satisfactory (OK)? At this point the user typed yes, telling the system to actually put those seven lines into the next seven

lines of the TOPIC buffer. If the processing had been unsatisfactory, the user could have jumped to the SEGMENTATION mode, changed the rules, jumped back to TOPIC, and reprocessed the data using the new rules before proceeding with the next processing step.

The user then entered the next mode, LINGUISTIC1, and started processing. The EXTRACTION rules were applied to the seven lines of data in TOPIC and the system indicated that the processing should consist of placing these lines in LINGUISTIC1 unchanged. Note that the system indicated that line 1 from TOPIC was transformed into a single line in LINGUISTIC1, etc., as opposed to the previous step where one line in TEXT was transformed into seven lines in TOPIC.

1. (EQ D 5)
   FROM : D IS 5 ;
   OK? yes batch suppress
   BATCH=T
   suppress=T
   AUTOMATIC=T
next go

Processing in LINGUISTIC2 consisted of applying the SPACE and GRAMMAR rules to the data in LINGUISTIC1 to produce a parse. In step 1 the parse tree was printed and the user set the flag BATCH true to eliminate the OK? question (the system then assumes the answer is always yes) and the flag SUPPRESS true to eliminate further printing of the parse trees. Then, before going to the next mode in the control cycle, the user set the flag AUTOMATIC true so the system would automatically step through the appropriate run modes executing GO. At this point the LINGUISTIC2 buffer held the seven sets of semantic elements shown above.

Processing in SEMANTIC1 consisted of applying the INTEGRATION rules to the semantic elements in LINGUISTIC2. As indicated above there were five applications of the rules. Processing in SEMANTIC2 consisted of applying the NORMALIZATION rules to the seven sets of elements in SEMANTIC1. There were two applications of the rules, and five sets of elements were left in SEMANTIC2. Processing in SEMANTIC3 consisted of applying the GROUPING rules, which are not explicit. These rules simply attempted to pull from SEMANTIC2 one operator element and its associated knowledge elements. Since no operator elements were present, it pulled all the elements from SEMANTIC2.

GRAPHIC1 MODE

1. (BECAUSEOF ((EQ D 5)) ((EQ T 8)))
   FROM : (BECAUSEOF ((EQ D 5)) ((EQ T 8)))
   OK? yes
   BATCH=T
   DO YOU REALLY WANT BOTH AUTOMATIC=T AND BATCH=T ? yes
   suppress=T
   AUTOMATIC=T
next go

Processing in GRAPHIC1 consisted of applying the UNKNOWNS rules, which are not explicit. These rules involve searching the existing PBG for elements that match the elements containing unknowns. In this simple example no matches were found because the PBG had not yet been grown. Thus, in step 3 when the unknown carry <C> was not found, the user told the system to replace its processing result with (BECAUSEOF ((EQ C 1)) ((ODD R)) ). This was put into line 3 of the GRAPHIC1 buffer, rather than the result containing <C>. In effect the user told the system that the value of <C> was C2, i.e., that the unknown carry was the carry into the second column (the L+L=R column).

Processing in GRAPHIC2 and GRAPHIC3 occurred as follows: GRAPHIC2 was entered and the elements from line 1 of GRAPHIC1 were processed interactively to determine their operator groups. GRAPHIC3 was then entered and these groups were grown as new nodes in the PBG. Next GRAPHIC2 was reentered and the elements
from line 2 of GRAPHIC 1 processed. This graphic2-
graphic3 loop was repeated for each line in GRAPHIC 1. Below is shown only one of these loops: processing and growing the elements from line 3 of GRAPHIC 1.

GRAPHIC3 MODE FINISHED

In GRAPHIC 2 the system queried the user to determine possible origins (operators and their inputs) for the elements in question. This information was represented as an origin tree as shown above. This tree is displayed below in a more conventional style.

output:
(ODD R)
operators:
(PC 2)

input/output:
(EQ C2 1)

operators:
(AV C2)

input:
(EQ D 5) (EQ C1 0)

Figure 7. Origin Tree

The system analyzes the tree and decides which path represents the best origin for the top element, in this case (ODD R). Here there are only two alternatives: the path with the operator: assign a value to the carry into column 2, (AV C2), and the path with the operator: process column 1, (PC 1). The system chooses the latter, based on implicit ORIGIN rules which tell it to choose between operators by rating them according to their inputs. The decision function currently in use is:

Choose to maximize: (3 x used-inputs) - (unused-inputs)

Space limitations prevent us from including the entire listing.

In GRAPHIC 3 the two groups from GRAPHIC 2 were incorporated into the PBG. The second group, with (ODD R) as the output, conflicted with an existing group in the PBG and led to restructuring of the PBG to resolve the conflict. Conflicts were defined by the CONFLICT rules, the type of restructuring by the PBG rules.

After all the data from GRAPHIC 1 was processed in GRAPHIC 2 and GRAPHIC 3 the contents of GRAPHIC 3 were displayed. Each line in the display represents a node in the PBG. Node 10 contains the operator: test to see if R can have the digit 5 as a value. (TD R 5). Figure 8 shows this PBG in the conventional representation. Note that the conflict between (AEQ R 4) and (ODD R) led to a back-up that abandoned nodes 4, 5 and 6. Thus the currently active nodes, the ones that define the current context, are those joined by the heavy lines in Figure 8.

5. Discussion

The initial program, PAS-I, is an artificial intelligence program by any reasonable criteria. The task it attempts, the inference from verbal behavior to Problem Behavior Graph, is a task requiring intelligence when done by human beings. The mechanisms used are those common to other artificial intelligence programs that tackle somewhat similar tasks: grammars to deal with the surface structure of natural language, representation of knowledge, matching, and heuristic search to infer information not directly expressed in the utterances.

PAS-II is a program that accomplishes the same task as PAS-I. Hence, it too is an artificial intelligence program. But when looked at structurally it more closely resembles a data processing framework or, possibly, a language. Something has happened in going from PAS-I to PAS-II, something worth identifying and discussing.

Let us start with Planner (3) and QA4 (8). These systems are languages for writing programs to perform a class of artificial intelligence tasks. The

Conflict and PBG rules are described in detail in an earlier paper (15).

There are other representatives of this class, e.g., POPLER (1) and Conniver (10, 11).
Figure 8. Problem Behavior Graph for Cryptarithmetic

KEY:

| Knowledge | Operators |
|-----------|-----------|
| =         | RECALL    |
| assign equal | PC      |
| not equal | AV        |
|           | TD        |

- equal
- recall element
- process column
- assign value
- test digit
exact boundaries of these tasks are obscure but their central core is clear and includes a large fraction of the tasks for which heuristic programs have been built -- theorem proving, robot planning, symbolic manipulation, etc. These systems were formed, essentially, by taking a list processing framework and embedding within it some of the ad hoc mechanisms developed for particular heuristic programs. They include backtrack, a generalized matching facility, a global data base (accessed by pattern matching) and multiprocessing control. Embedding these mechanisms within a language makes possible their use in novel combinations (and in interaction with the other mechanisms available in higher languages).

This same embedding of mechanisms into a language system has occurred in the transition from PAS-I to PAS-II. PAS-II provides a framework within which a class of AI programs can be easily constructed. This class is not the same as that of the Planner/QA system, which is more "mainline" artificial intelligence. Rather, it appears to be characterized as linguistic data processing, the essential feature being the processing of long sequences of data (rather than just a sentence at a time). This class includes, of course, protocol analysis. It also includes a number of other tasks: content analysis of more classical varieties (9), problem space construction (2), test grading, and what is coming to be called semantic filtering.

The embodiment of mechanisms into a language framework has occurred at two levels in PAS-II, one corresponding roughly to that of Planner/QA and the other more specialized. The first level is represented by the PAS-II framework of run modes, rule modes, common command language, editing system, and control structure. This includes a set of mechanisms for the data base (the run modes), a matching facility (the common mechanism for how the rules work on data), and a backtrack facility (the saving of buffers so that processing can be undone). Added to this is the explicit control structure for processing within a stage and passing through the stages, which corresponds to a weak method (4) in the same sense as Newell's basic methods or the basic methods built into the goal construct in Planner/QA. These provide a schema of operation which, though almost content free, is still a rational procedure for achieving the overall goal. The mechanisms adopted in PAS-II are somewhat more shaped than their counterparts in Planner/QA, e.g., there is not a single global data base or one stratified by a general context mechanism, rather the data is organized into homogeneous groups (the modes) along structural lines.

The second level is the specialization of the various modes to specific subtasks inherent in tasks of the class: segmentation, parsing, normalization, etc. The specialized rule systems contain the knowledge about the processing. Thus writing any sort of legal rules within a given rule system generates processing of the right sort (though it may not do the right task). In this respect providing a single generalized rule system or scheme for pattern matching and pattern evoked actions (in the manner of Planner/QA) would move more of the knowledge required back across the boundary from the language system (PAS-I) to the coding within the system (the user program in PAS-II, which is the set of actual rules in the rule modes).

As one moves PAS-II in the direction of a generalized system for a wider class of problems, one can expect the collection of rule modes to increase, becoming eventually, a library in the classic subroutine library sense. The system designer is then faced with the problem of providing these modes with the rules needed to define processing in the various problem domains. However, one advantage of specialized rule systems is that when their structure is highly constrained it becomes easy to predict the effect of modifying rules in the system (as compared to predicting the effect of modifying statements in a general programming language). This sets the stage for the development of self-modifying systems which rewrite their own rules or, in effect, learn to improve their performance in some data processing task (12, 13). Such a capability in an interactive PAS-II-like system would enable the system to build or modify its own rules for a particular problem domain, using feedback from the user to direct the search for good sets of rules.

The evolution from PAS-I to PAS-II in analogy to the more general evolution going on toward planner-like language systems should add to the awareness that embedding mechanisms in language remains a potent scheme for making advances in artificial intelligence.

Acknowledgments

This paper will appear in the preprints for the third International Joint Conference on Artificial Intelligence (IJCAI-73). This research was supported in part by Research Grant MH-07732 from the National Institutes of Health and in part by the Advanced Research Projects Agency of the Office of the Secretary of Defense (D4420-74-C-0107) which is monitored by the Air Force Office of Scientific Research.
