Abstract

We find, in the form of a continued fraction, the generating function for the number of (132)-avoiding permutations that have a given number of (123) patterns, and show how to extend this to permutations that have exactly one (132) pattern. We find some properties of the continued fraction, which is similar to, though more general than, those that were studied by Ramanujan.
A (132) pattern (resp. a (123) pattern) in a permutation $\pi$ of $|\pi|$ letters is a triple $1 \leq i < j < k \leq n$ of indices for which $\pi(i) < \pi(k) < \pi(j)$ (resp. $\pi(i) < \pi(j) < \pi(k)$). Let $f_r(n)$ denote the number of permutations $\pi$ of $n$ letters that have no (132) patterns and exactly $r$ (123) patterns. Our main result is the following.

**Theorem 1** The generating function for the $\{f_r(n)\}$ is

$$
\sum_{r,n \geq 0} f_r(n) z^n q^r = \frac{1}{1 - \frac{z}{1 - \frac{z q}{1 - \frac{zq^3}{1 - \frac{zq^6}{1 - \cdots}}}}},
$$

in which the $n$th numerator is $z q^{\binom{n}{2}}$.

We think it is remarkable that such a continued fraction encodes information about (132)-avoiding permutations. We will first prove the theorem, and then study some consequences and generalizations.

## 1 The patterns

Let the weight of a permutation $\pi$ of $|\pi|$ letters be $z^{|\pi|} q^{|123(\pi)|} q^{|12(\pi)|}$, in which $|123(\pi)|$ is the number of patterns (123) (rising triples) in $\pi$, and $|12(\pi)|$ is the number of rising pairs in $\pi$. Let

$$
P(q,z,t) = \sum'_\pi \text{Weight}(\pi),
$$

where the sum extends over all (132)-avoiding permutations $\pi$.

If $\pi$ is a (132)-avoiding permutation on $\{1, 2, \ldots, n\}$, $n > 0$ and the largest element, $n$, is at the $k$th position, i.e., $\pi(k) = n$, then by letting $\pi_1 := \{\pi(i)\}_{1}^{k-1}$ and $\pi_2 := \{\pi(i)\}_{k+1}^{n}$, we have that every element in $\pi_1$ must be larger than every element of $\pi_2$, or else a (132) would be formed, with the $n$ serving as the ‘3’ of the (132). Hence, $\pi_1$ is a permutation of the set $\{n - k + 1, \ldots, n - 1\}$, and $\pi_2$ is a permutation of the set $\{1, \ldots, n - k\}$. Furthermore, $\pi_1$ and $\pi_2$ are each (132)-avoiding. Conversely, if $\pi_1$ and $\pi_2$ are (132)-avoiding permutations on $\{n - k + 1, \ldots, n - 1\}$ and $\{1, \ldots, n - k\}$ respectively (for some $k$, $1 \leq k \leq n$), then $(\pi_1 \pi_2)$ is a nonempty (132)-avoiding permutation.

Thus we have:

$$
|123(\pi)| = |123(\pi_1)| + |123(\pi_2)| + |12(\pi)|,
$$
since a (123) pattern in \( \pi \equiv (\pi_1 n \pi_2) \) may either be totally immersed in the \( \pi_1 \) part, or wholly immersed in the \( \pi_2 \) part, or may be due to the \( n \) serving as the ‘3’ of the (123), the number of which is the number of (12) patterns in \( \pi_1 \).

We also have
\[
|12(\pi)| = |12(\pi_1)| + |12(\pi_2)| + |\pi_1|,
\]
and, of course
\[
|\pi| = |\pi_1| + |\pi_2| + 1.
\]

Hence,
\[
\text{Weight}(\pi)(q, z, t) := q^{123(\pi)} z^{|\pi|} t^{|12(\pi)|}
\]
\[
= q^{123(\pi_1) + |12(\pi_2)| + |12(\pi)|} z^{|\pi_1| + |\pi_2| + 1} t^{|12(\pi_1)| + |12(\pi_2)| + |\pi_1|}
\]
\[
= zq^{123(\pi_1)} ((qt)^{12(\pi_1))} |zt|^{\pi_1} q^{123(\pi_2)} t^{12(\pi_2)} z^{|\pi_2|}
\]
\[
= z\text{Weight}(\pi_1)(q, zt, qt)\text{Weight}(\pi_2)(q, z, t).
\]

Now sum over all possible (132)-avoiding permutations \( \pi \), to get the functional equation
\[
P(q, z, t) = 1 + zP(q, zt, qt)P(q, z, t),
\]
in which the 1 corresponds to the empty permutation.

Next let \( Q(q, z, t) \) be the sum of all the weights of all permutations with exactly ONE (132) pattern. By adapting the argument from Miklós Bóna’s paper [1] we easily see that \( Q(q, z, t) \) satisfies
\[
Q(q, z, t) = zP(q, zt, qt)Q(q, z, t) + zQ(q, zt, qt)P(q, z, t) + t^2 z^2 P(q, zt, qt)(P(q, z, t) - 1).
\]

This holds since our sole (132) pattern can either appear in the elements
(a) before \( n \),
(b) after \( n \), or
(c) with \( n \) as the ‘3’ in the (132) pattern.

The term \( zP(q, zt, qt)Q(q, z, t) \) corresponds to (a), \( zQ(q, zt, qt)P(q, z, t) \) corresponds to (b), and \( t^2 z^2 P(q, zt, qt)(P(q, z, t) - 1) \) corresponds to (c). We see that case (c) follows since \( \pi = (\pi_1, n - k, n, \pi_2) \), where \( \pi_1 \) is a permutation of \([n - k + 2, \ldots, n - 1], \pi_2 \) is a permutation of \([1, \ldots, n - k - 1] \cup \{n - k + 1\} \), and \( k \neq n \).
2 The fractions

Here we study this generating function \( P(q, z, t) \) further, and find that it is a pretty continued fraction, and discover a fairly explicit form for its numerator and denominator.

First, from (5) we have that
\[
P(q, z, t) = \frac{1}{1 - zP(q, zt, tq)},
\]
and so by iteration we have the continued fraction,
\[
P(q, z, t) = \frac{1}{1 - \frac{z}{1 - \frac{zt}{1 - \frac{zt^2q}{1 - \frac{zt^3q^3}{1 - \frac{zt^4q^6}{\ldots}}}}}}.
\]

Now let
\[
P(q, z, t) = \frac{A(q, z, t)}{B(q, z, t)}.
\]

Then substitution in (5) shows that \( A(q, z, t) = B(q, zt, tq) \), and therefore
\[
P(q, z, t) = \frac{B(q, zt, tq)}{B(q, z, t)}
\]
where \( B \) satisfies the functional equation
\[
B(q, z, t) = B(q, zt, tq) - zB(q, t^2qz, tq^2).
\]

To find out more about the form of \( B \) we write
\[
B(q, z, t) = \sum_{m \geq 0} \phi_m(q, t)z^m.
\]

Then \( \phi_0 = 1 \), and
\[
\phi_m(q, t) = t^m\phi_m(q, qt) - t^{2m-2}q^{m-1}\phi_{m-1}(q, tq^2),
\]
for \( m = 1, 2, 3, \ldots \). It is easy to see by induction that
\[
\phi_m(q, t) = -\sum_{j \geq 2} t^{jm-2}q^{m(j-2)+3}\phi_{m-1}(q, tq^j). \quad (m \geq 1; \phi_0 = 1)
\]
For example, we have

\[ \phi_1(q,t) = - \sum_{j \geq 0} t^j q^{(j)}, \]

and

\[ \phi_2(q,t) = \sum_{j, \ell \geq 2} t^{\ell + 2j - 4} q^{\frac{1}{2} \ell^2 + j^2 - \frac{5}{2} \ell j - 5j + 6}. \]

In general, the exponent of \( t \) in \( \phi_m(q,t) \) will be a linear form in the \( m \) summation indices, plus a constant, and the exponent of \( q \) will be an affine form in these indices, i.e., a quadratic form plus a linear form plus a constant. Let's find all of these forms explicitly.

Hence suppose in general that

\[ \phi_m(t) = (-1)^m \sum_{j \geq 0} t^{a_m j + b_m} q^{(j, Q_m j) + c_m j + d_m}, \]

in which \( j \) is the \( m \)-vector of summation indices, \( Q_m \) is a real symmetric \( m \times m \) matrix to be determined, \( a_m, c_m \) are \( m \)-vectors, and \( b_m, d_m \) are scalars. Inductively we find that

\[ a_m = \{ r \}_{r=1}^m, \]
\[ b_m = -2m, \]
\[ c_m = \{ -5r/2 \}_{r=1}^m, \]
\[ d_m = 3m. \]

The \( m \times m \) matrix \( Q_m \) is \( \{ \min(r,s)/2 \}_{r,s=1}^m \). Thus we have the following formula for \( B \).

**Theorem 2** The denominator \( B(q,z,t) \) of the grand generating function \( P(q,z,t) \) is explicitly given by

\[ B(q,z,t) = 1 + \sum_{m=1}^{\infty} (-zq^3 t^{-2})^m \sum_{j_1, \ldots, j_m \geq 2} t^{\sum_{r=1}^m r j_r} q^{\frac{1}{2} \sum_{r,s=1}^m \min(r,s) j_r j_s - 5 \sum_{r=1}^m r j_r}. \]  

(9)

### 3 The series computations

If \( f_r(n) \) denotes the number of permutations of \( n \) letters that contain no pattern (132) and have exactly \( r \) (123)'s, we write \( AR(r,z) := \sum_n f_r(n) z^n \). Then \( AR(r,z) \) is the coefficient of \( q^r \) in the
series development of $P(q, z, 1)$ of (2). That is, we have

$$\frac{1}{1 - \frac{z}{1 - \frac{zq}{1 - \frac{zq^3}{1 - \frac{zq^6}{\ldots}}}}} = \sum_{r \geq 0} AR(r, z)q^r \tag{10}$$

¿From (10) we see that if we terminate the fraction $P(q, z, 1)$ at the numerator $q^N$, say, then we’ll know all of the $\{AR(r, z)\}_{r=0}^N$ exactly.

Further, if we know the denominator $B(q, z, t)$ in (7) exactly through terms of order $q^N$, then by carrying out the division in (7) and keeping the same accuracy, we will, after setting $t = 1$, again obtain all of the generating functions $\{AR(r, z)\}_{r=0}^N$ exactly.

Finally, to find the denominator $B(q, z, t)$ in (7) exactly through terms of order $q^N$, it is sufficient to carry out the iteration that is implicit in (8) $N$ times, since further iteration will affect only the terms involving powers of $q$ higher than the $N$th.

In that way we computed the $AR(r, z)$’s for $0 \leq r \leq 15$ in a few seconds, as is shown below in the initial section of the series (10):

$$\frac{1-z}{1-2z} + \frac{z^3q}{(1-2z)^2} + \frac{(1-z)z^4q^2}{(1-2z)^3} + \frac{(1-z)^2z^5q^3}{(1-2z)^4} + \frac{z^4(-1+6z-13z^2+11z^3-3z^4+z^5)}{(-1+2z)^5} \frac{q^4}{(1-2z)^5} + \frac{z^5(2-14z+37z^2-44z^3+22z^4-4z^5+z^6)}{(1-2z)^6} \frac{q^5}{(1-2z)^6} + \frac{(1-z)^2z^6(-3+18z-37z^2+27z^3-3z^4+z^5)}{(-1+2z)^7} \frac{q^6}{(1-2z)^7} + \frac{z^5(1-12z+64z^2-196z^3+373z^4-450z^5+343z^6-164z^7+47z^8-6z^9+z^{10})}{(1-2z)^8} q^7 + \ldots$$

If $g_r(n)$ denotes the number of permutations of $n$ letters that contain 1 (132) pattern and have exactly $r$ (123)’s, we write Aaron(r,z):=$\sum_{n} g_r(n)z^n$. Then Aaron(r,z) is the coefficient of $q^r$ in the series development of $Q(q, z, 1)$ of (8). Since we have a very quick method to compute $P(q, z, 1)$, we can iterate equation (4) to compute the Aaron(r,z)’s. Shown below are the Aaron(r,z)’s for $0 \leq r \leq 6$, that were computed in a few minutes.
\[
\frac{z^3}{(1-2z)^3} + \frac{2z^5}{(1-2z)^5} q + \frac{z^4(z^3 - 6z^2 + 4z - 1)}{(1-2z)^4} q^2 + \frac{2z^5(z-1)(5z^2 - 4z + 1)}{(1-2z)^6} q^3
\]
\[
+ \frac{z^6(z^5 + 12z^4 - 55z^3 + 65z^2 - 30z + 5)}{(1-2z)^6} q^4 + \frac{-2z^7(z^6 + 6z^5 - 40z^4 + 80z^3 - 69z^2 + 27z - 4)}{(1-2z)^7} q^5
\]
\[
+ \frac{-z^6(z-1)(3z^8 + 13z^7 - 77z^6 + 240z^5 - 329z^4 + 231z^3 - 91z^2 + 20z - 2)}{(1-2z)^8} q^6
\]
