**Abstract:** A series of novel chiral nonmetallocene pincer-type rare-earth metal dialkyl complexes bearing the chiral monoanionic tridentate \(C_2\)-symmetric 1,3-bis(oxazolinymethylidene)isoindoline (BOXMI-H) ligand (BOXMI)Ln(CH\(\text{SiMe}_3\))\(_2\) 1–3 (1: Ln = Sc, yield = 57%; 2: Ln = Lu, yield = 55%; 3: Ln = Y, yield = 62%) have been prepared in moderate yields via the acid-base reaction between the BOXMI ligand and rare-earth metal tri(trimethylsilylmethyl) complexes. The X-ray diffractions show that both of the complexes 1 and 2 contain one BOXMI ligand and two trimethylsilylmethyl ligands, adopting a distorted trigonal bipyramidal configuration. In the presence of a cocatalyst such as borate and AlR\(_3\), these complexes 1–3 exhibit high activities of up to \(6.8 \times 10^4\) (g of polymer)/(mol Ln h) and high cis-1,4 selectivities of up to 97% in the polymerization of isoprene in toluene, yielding the cis-1,4-polyisoprenes with heavy molecular weights (\(M_n\) of up to 710,000 g/mol) and bimodal molecular weight distributions (\(M_w/M_n = 2.0–4.5\)).

**Keywords:** rare-earth metal complexes; 1,3-bis(oxazolinymethylidene)isoindoline ligand; polymerization; isoprene; cis-1,4 selectivity

1. **Introduction**

The development of highly efficient and selective organometallic catalysts is a permanent topic for olefin polymerization, which brings new opportunities for the synthesis of high-performance (co)polymers with precisely controlled structures and excellent properties [1–6]. Recently, cis-1,4-polyisoprene (CPIP) has attracted much attention from the academia and industry in the view that it is the principal component of natural rubber and serves as a strategically important elastomer used for pneumatic tires [7–11]. In general, the practical and most common synthesis method of CPIP is the coordination–insertion polymerization of isoprene (IP) by using homogeneous organometallic catalysts based on rare-earth metals [12–18]. So far, a large number of the rare-earth metal catalyst precursors bearing a different chelating ligand have been reported for the cis-1,4-polymerization of IP [19–27]. Among these, the nonmetallocene pincer-type rare-earth metal complexes bearing the monoanionic tridentate \(C_2\)-symmetric ligands usually exhibit both high activities and high cis-1,4 selectivities in the polymerization of IP [28–30] (Chart 1). In 2007, the rare-earth metal alkyl complexes bearing a bis(phosphinophenyl)amido (PNP) ligand were reported by Hou et al., showing high activities of up to \(4.9 \times 10^5\) (g of polymer)/(mol Ln h) and high cis-1,4 selectivities of up to 99% in the living cis-1,4-polymerization of isoprene [31]. In 2008, the aryldiimine (NCN)-ligated rare-earth metal dichlorides were developed by Cui and co-workers. These complexes can serve as catalyst precursors in the cis-1,4-polymerization of isoprene with high activities of up to \(4.1 \times 10^5\) (g of...
polymer) / (mol\textsubscript{Ln} h) and high cis-1,4 selectivities of around 98.8% [32]. Subsequently, Cui also reported the cis-1,4-polymerization of isoprene by using the bis(carbene)phenyl (CCC) rare-earth metal dibromides (activities of up to 1.3 × 10\textsuperscript{5} (g of polymer) / (mol\textsubscript{Ln} h) and cis-1,4 selectivities of up to 99.6%) [33], the bis(phosphino)carbazolide (PNP)-chelated rare-earth metal complexes (activities of up to 8.2 × 10\textsuperscript{5} (g of polymer) / (mol\textsubscript{Ln} h) and cis-1,4 selectivities of up to 99%) [34], and the bis(pyridol-1-y1)pyrrolyl or bis(piperidino)methylene) pyrrolyl [NNN]-ligated rare-earth metal complexes (activities up to 2.7 × 10\textsuperscript{4} (g of polymer) / (mol\textsubscript{Ln} h) and cis-1,4 selectivities ca. 94.1%) [35]. In 2013, Lu and coworkers described the cis-1,4-polymerization of isoprene by use of the bis(oxazoliny1)phenyl (NCN)-ligated rare-earth metal dichlorides with activities of up to 4.1 × 10\textsuperscript{5} (g of polymer) / (mol\textsubscript{Ln} h) and cis-1,4 selectivities of up to 99.5% [36]. By contrast, the rare-earth metal complexes bearing the pincer-type NNN ligand exhibited unsatisfactory activity (<10\textsuperscript{5} (g of polymer) / (mol\textsubscript{Ln} h)) and cis-1,4 selectivity (<94%) in the polymerization of IP [37]. Therefore, it is of great interest to develop higher-efficiency and selective NNN-chelated rare-earth metal complexes for the cis-1,4-polymerization of IP.

![Chart 1](image)

**Chart 1.** The previous pincer-type rare-earth metal catalysts bearing tridentate C\textsubscript{2}-symmetric chelating ligand.

Recently, we have paid attention to the synthesis of the NNN-ligated rare-earth metal dialkyl complexes and their applications in IP polymerization. In 2013, we reported the synthesis of a series of chiral (S,S)-bis(oxazoliny1)phenylamine ((S,S)-BOPA)-ligated rare-earth metal dialkyl complexes [(S,S)-BOPA]Ln(CH\textsubscript{2}SiMe\textsubscript{3})\textsubscript{2} (1–2; 1: Ln = Sc; 2: Ln = Lu). In the presence of an activator with or without a small amount of Al\textsubscript{5}Bu\textsubscript{3}, the dialkyl complexes 1 and 2 exhibited very high activities of up to 6.8 × 10\textsuperscript{5} (g of polymer) / (mol\textsubscript{Ln} h) and trans-1,4 selectivities of up to 100% in the quasi-living polymerization of isoprene, yielding trans-1,4-PiPs with moderate molecular weights (M\textsubscript{n} = (0.2–1.0) × 10\textsuperscript{5} g / mol) and narrow molecular weight distributions (M\textsubscript{w} / M\textsubscript{n} = 1.02–2.66) [38]. Recently, we also reported that the 1,3-bis(2-pyridylimino)isoindoline-ligated rare-earth metal dialkyl complexes showed very high activities of up to 1.9 × 10\textsuperscript{6} (g of polymer) / (mol\textsubscript{Ln} h) and high cis-1,4 selectivities of >99% in the polymerization of isoprene in the presence of an activator and AlR\textsubscript{3}, affording CIPP with heavy molecular weights (M\textsubscript{n} up to 610,000 g / mol) and narrow to moderate molecular weight distributions (M\textsubscript{w} / M\textsubscript{n} = 1.26–2.08) [39]. These results demonstrated that the
effective adjustment of the skeleton of the pincer-type NNN ligand have an important impact on the
catalyst performance of these rare-earth metal complexes in IP polymerization, which rouses
our interests to explore more NNN-ligated rare-earth metal dialkyl complexes and to detect their
catalytic performance in the selective polymerization of IP. 1,3-Bis(oxazolinylmethyldiene)isoindoline
(BOXMI-H) ligand, which has structural characteristics of both the (S,S)-bis(oxazolinylphenyl)amine
and 1,3-bis(2-pyridyldimino)isoindoline ligands, is an interesting chiral tridentate C₂-symmetric NNN
ligand for the organometallic complex based on transition metals for the asymmetric reaction [40–43].
 Until now, the BOXMI-H-ligated rare-earth metal complexes have never been reported, and their
applications for the coordination–insertion polymerization of olefin have never been investigated, as far
as we are aware. Herein, we report the synthesis of three pincer-type BOXMI-H-ligated rare-earth metal
dialkyl complexes (BOXMI)Ln(CH₂SiMe₃)₂ 1–3 (1: Ln = Sc; 2: Ln = Lu; 3: Ln = Y) via the acid–base
reaction between the BOXMI-H ligand and rare-earth metal trialkyl complexes. These complexes
1–3 exhibited high activities of up to 6.8 × 10⁴ (g of polymer)/(mol·h) and high cis-1,4 selectivities of
up to 97% in the IP polymerization in toluene, affording cis-1,4-polyisoprenes with heavy molecular
weights (Mₙ of up to 710,000 g/mol) and bimodal molecular weight distributions (Mₙ/Mₚ = 2.0–4.5).

2. Experiment

2.1. Materials and Method

All catalysts and the polymerization procedure were carried out in a nitrogen-filled MBraun
glovebox. [Ph₅C][B(C₆F₅)₄], [PhMe₂NH][B(C₆F₅)₄], and B(C₆F₅)₃ were purchased from J&K Chemical
(Shanghai, China). LiCH₂SiMe₃ (1.0 M solution in pentane) and LnCl₃ were purchased from Aldrich
(St. Louis, MO, USA). Al²Bu₃ (1.1 M solution in heptane), AlMe₃ (1.0 M solution in Toluene),
AlEt₃ (0.6 M solution in heptane), Phthalimides, (Carbethoxymethylene)triphenylphosphorane,
(S)-amino alcohol, NaH, PPh₃, Et₃Si, ClSiMe, Na₂SO₄, CaH₂, dichloromethane, petroleum ether,
and methanol were obtained from Energy Chemistry (Shanghai, China). BOXMI-H ligand [40] and
Ln(CH₂SiMe₃)(THF)₂ [44] were prepared according to the literature. Isoprene was purchased from
J&K Chemical (Beijing, China), and dried through CaH₂. Toluene, THF, and hexane were purified by a
solvent purification system (SPS-800, Mbraun, Shanghai, China) and dried over Na in the glovebox. The deuterated solvents C₆D₆ (99.6 atom% D) and CDCl₃ (99.8 atom% D) were purchased from
Cambridge Isotope.

Elemental analyses, ¹H NMR and ¹³C NMR, of rare-earth metal complexes were performed
according to the literature [38]. Polysoprene samples of gel permeation chromatography (GPC)
and differential scanning calorimetry (DSC) measurements were conducted according to the literature [38].
The test method of crystals of complexes 1 and 2 was performed according to the literature [38].

Crystallographic data of complexes 1 and 2 (excluding structure factors) have been deposited
to the Cambridge Crystallographic Data Centre as supplementary publication nos. CCDC-1539945
(1) and 1536645 (2), containing the supplementary crystallographic data for this paper. These data
can be obtained free of charge via https://www.ccdc.cam.ac.uk/structures/ from the Cambridge
Crystallographic Data Centre.

2.2. Synthesis of Chiral BOXMI-H-Ligated Rare-Earth Metal Dialkyl Complexes

Here we outline the synthesis of the BOXMI-H-ligated rare-earth metal dialkyl complex
(BOXMI)Sc(CH₂SiMe₃)₂ (1). To a colorless toluene solution (8.0 mL) of Sc(CH₂SiMe₃)₃(THF)₂ (208 mg,
0.461 mmol) was added a solution of the BOXMI-H ligand (200 mg, 0.461 mmol) in toluene (10.0 mL)
at room temperature. The reaction mixture was stirred at room temperature for 4 h. After removal
of the solution in vacuo, the resulting solid was recrystallized from hexane/toluene at −30 °C to
give 1 (171 mg, yield ca. 57%). ¹H NMR (400 MHz, C₆D₆) δ: 7.25–7.23 (m, 6H), 7.18–7.14 (m, 4H),
7.11–7.09 (m, 2H), 7.59 (s, 2H), 5.56 (dd, 2H, J = 4 Hz, 8 Hz), 4.27 (t, 2H, J = 8 Hz), 3.91 (dd, 2H, J = 4 Hz,
8 Hz), 0.17 (d, 2H, J = 12 Hz), 0.02 (s, 18H, CH₂Si(CH₃)₃), and −0.54 (d, 2H, J = 12 Hz). ¹³C NMR
The following outlines the synthesis of BOXMI-H-ligated rare-earth metal dialkyl complex (BOXMI)Lu(CH₂SiMe₃)₂ (2). To a colorless toluene solution (5.0 mL) of Lu(CH₂SiMe₃)₂(THF)₂ (268 mg, 0.461 mmol) was added a solution of the BOXMI-H ligand (200 mg, 0.461 mmol) in toluene (10.0 mL) at room temperature. The reaction mixture was stirred at room temperature for 4 h. After removal of the solution in vacuo, the resulting solid was recrystallized from hexane/toluene at −30 °C to give 2 (198 mg, yield ca. 55%). ¹H NMR (400 MHz, C₆D₆) δ: 7.18–7.12 (m, 12H), 7.09–7.07 (m, 2H), 6.92–6.90 (m, 2H), 5.72 (s, 2H), 5.41 (dd, 2H, J = 4 Hz, 8 Hz), 4.17 (t, 2H, J = 8 Hz), 3.81 (dd, 2H, J = 4 Hz, 8 Hz), 0.05 (s, 18H), −0.62 (d, 2H, J = 12 Hz), and −1.44 (d, 2H, J = 12 Hz). ¹³C NMR (100 MHz, C₆D₆) δ: 170.81, 163.41, 141.12, 138.85, 130.06, 129.48, 128.81, 127.97, 121.08, 82.50, 75.65, 68.91, 43.56, and 4.00. Anal. Calcd (%) for C₃₈H₄₄N₃O₂ScSi: C, 55.32; H, 5.67; N, 5.37. Found: C, 55.32; H, 5.71; N, 5.41.

The following outlines the synthesis of BOXMI-H-ligated rare-earth metal dialkyl complex (BOXMI)Y(CH₂SiMe₃)₂ (3). To a colorless toluene solution (5.0 mL) of Y(CH₂SiMe₃)₂(THF)₂ (228 mg, 0.461 mmol) was added a solution of the BOXMI-H ligand (200 mg, 0.461 mmol) in toluene (10.0 mL) at room temperature. The reaction mixture was stirred at room temperature for 4 h. After removal of the solution in vacuo, the resulting solid was recrystallized from hexane/toluene at −30 °C to give 3 (199 mg, yield ca. 62%). ¹H NMR (400 MHz, C₆D₆) δ: 7.18–7.12 (m, 12H), 7.09–7.07 (m, 2H), 6.92–6.89 (m, 2H), 5.72 (s, 2H), 5.40 (dd, 2H, J = 4 Hz, 8 Hz), 4.17 (t, 2H, J = 8 Hz), 3.81 (dd, 2H, J = 4 Hz, 8 Hz), 0.05 (s, 18H), −0.41 (d, 2H, J = 12 Hz), and −1.30 (d, 2H, J = 12 Hz). ¹³C NMR (100 MHz, C₆D₆) δ: 170.80, 163.13, 141.73, 138.9, 129.97, 129.56, 127.97, 121.00, 82.26, 75.35, 68.85, 37.29, 37.08, and 3.88. Anal. Calcd (%) for C₃₈H₄₄N₃O₂YSi: C, 62.14; H, 6.37; N, 6.04. Found: C, 62.10; H, 6.35; N, 6.01.

2.3. A Typical Procedure for Isoprene (IP) Polymerization

A detailed polymerization procedure of isoprene is described here as a typical example. In a glovebox at 25 °C, to a toluene solution (8 mL) of Al₂Bu₃ (181 µL, 1.1 M, 200 µmol) was added a toluene solution (8 mL) of complex 1 (0.013 g, 20 µmol), a toluene solution (2.5 mL) of [Ph₂C][B(C₆F₅)₄] (0.018 g, 20 µmol), and isoprene (0.27 g, 4 mmol) in succession. In a 50 mL round bottom flask, the reaction mixture was stirred at room temperature for 4 h. After removal of the solution in vacuo, the resulting solid was recrystallized from hexane/toluene at −30 °C to give 1 (199 mg, yield ca. 62%). ¹H NMR (400 MHz, C₆D₆) δ: 7.18–7.12 (m, 12H), 7.09–7.07 (m, 2H), 6.92–6.89 (m, 2H), 5.72 (s, 2H), 5.40 (dd, 2H, J = 4 Hz, 8 Hz), 4.17 (t, 2H, J = 8 Hz), 3.81 (dd, 2H, J = 4 Hz, 8 Hz), 0.05 (s, 18H), −0.41 (d, 2H, J = 12 Hz), and −1.30 (d, 2H, J = 12 Hz). ¹³C NMR (100 MHz, C₆D₆) δ: 170.80, 163.13, 141.73, 138.9, 129.97, 129.56, 127.97, 121.00, 82.26, 75.35, 68.85, 37.29, 37.08, and 3.88. Anal. Calcd (%) for C₃₈H₄₄N₃O₂YSi: C, 62.14; H, 6.37; N, 6.04. Found: C, 62.10; H, 6.35; N, 6.01.

3. Results and Discussion

3.1. Synthesis and Structural Characterization of BOXMI-Ligated Rare-Earth Metal Dialkyl Complexes 1–3

The acid–base reactions of the rare-earth metal trialkyl complexes Ln(CH₂SiMe₃)₃(THF)₂ and 1 equiv. of 1,3-bis(oxazolinymethylidene)isoindoline ligand (BOXMI-H) straightforwardly yielded the pincer-type NNN-ligated rare-earth metal dialkyl complexes (BOXMI)Ln(CH₂SiMe₃)₂ 1–3 (1: Ln = Sc, yield of 57%; 2: Ln = Lu, yield of 55%; 3: Ln = Y, yield of 62%) with moderate yields (Scheme 1).

These complexes 1–3 have good solubilities in common organic solvents such as hexane, toluene, and THF. In the ¹H NMR spectra of the complexes 1–3 in C₆D₆, all of the proton signals attributed to the NNN ligand except for the proton signal assigned to the N—H group were observed, suggesting the generation of a monoanionic NNN-chelating ligand in these complexes. The molar ratio of the integral areas of the signals for the NNN ligand and trimethylsilylmethyl ligand was 1:2 in each case. No THF molecule was detected in either case. Similarly to the rigid (S,S)-bis(oxazolinylphenyl)amine-ligated
rare-earth metal dialkyl complexes, all of the methylene protons of the Ln–CH₂SiMe₃ groups showed two doublets at a high field for 1 of 0.16 (d, 2H) and −0.56 ppm (d, 2H), for 2 at −0.62 (d, 2H) and −1.44 ppm (d, 2H), and for 3 at −0.41 (d, 2H) and −1.30 ppm (d, 2H) with a germinal H–H coupling constant of 12 Hz, respectively. These results may suggest that these complexes also have a rigid structure and the CH₂SiMe₃ groups in these complexes are fixed to some extent at the NMR time scale.

Scheme 1. Synthesis of BOXMI-H-ligated rare-earth metal dialkyl complexes 1–3. BOXMI: 1,3-bis(oxazolinymethylidene)isoindoline.

3.2. Single Crystals of Complexes 1 and 2

In the glovebox, single crystals of the complexes 1 and 2 suitable for an X-ray determination were grown from a mixed hexane/toluene solution at −30 °C. The ORTEP (Oak Ridge Thermal Ellipsoid Plot) drawings of the complexes 1–2 are shown in Figure 1. The selected bond distances and angles of these complexes 1 and 2 are summarized in Table 1. The X-ray diffraction study revealed that the dialkyl complexes 1 and 2 are isomorphous and isostructural. Both of these complexes contain one C₂-symmetric monoanionic tridentate NNN ligand and two trimethylsilylmethyl groups, adopting a distorted trigonal bipyramidal geometry. The bond distances of the chelating Ln−N(1), Ln−N(2), Ln−N(3), and Ln−C(29) as well as the Ln−C(33) bond increase in the order of 1 < 2 because of the ionic radius of the metal center in a trend of Sc (0.89 Å) < Lu (1.00 Å). The Ln−N(2) bonds of complexes 1 and 2 divide the angles of N(1)−Ln−N(3) (161.8(1)°–166.9(1)°) into two almost equal parts, N(1)−Ln−N(2) and N(2)−Ln−N(3) (81.1(1)°–83.9(1)°), implying the N(1), N(2), N(3), and Ln atoms are almost planar.

Figure 1. ORTEP drawings of complexes 1 and 2 with thermal ellipsoids of a 30% probability. Hydrogen atoms are omitted for clarity. ORTEP: Oak Ridge Thermal Ellipsoid Plot.
Table 1. Selected bond distances (Å) and angles (deg) of complexes 1 and 2.

| Bond Lengths and Bond Angles | 1         | 2         |
|------------------------------|-----------|-----------|

| C33–Ln–N3                    | 95.4(1)   | 97.4(8)   |

3.3. Cis-1,4-Polymerization of Isoprene by the Complexes 1–3/Activator/AlR₃ Catalytic Systems

The neutral complexes 1–3 alone and the complexes 1–3/AlR₃ binary systems were inactive for the IP polymerization, while the complexes 1–3/activator (such as [Ph₃C][B(C₆F₅)₄] (A), [PhMe₂NH][B(C₆F₅)₄] (B) and B(C₆F₅)₃ (C)) binary systems showed very low activities in the polymerization of IP. In the presence of both an activator and AlR₃, the complexes 1–3 could promote the cis-1,4-polymerization of IP similarly to the 1,3-bis(2-pyridylimino)isoindoline-ligated rare-earth metal dialkyl complexes [39], affording the cis-1,4-polyisoprenes (CPIPs) with heavy molecular weights (Mₙ of up to 710,000 g/mol) and moderate molecular weight distributions (Mₘ/Mₙ = 2.0–4.5). Some representative results are summarized in Table 2. As an activator, the trityl borate A and the anilinium borate B generally exhibited similar activities and cis-1,4 selectivities in the IP polymerization, while the neutral borane C was inert under the same conditions (Table 2, entries 1–5 and 7–10). For the Sc complex 1, the cis-1,4-PIPs obtained by borate A had heavier molecular weights and narrower molecular weight distributions (Table 2, entries 1–2 and 4–5), while for the Lu and Y complexes 2 and 3, the cis-1,4-PIPs obtained by borate A also had a heavier molecular weight but a broader molecular weight distribution (Table 2, entries 2 and 4–5). Similarly to the complex 1/activator/Al/iBu₃ systems, the complex 1/activator/AlEt₃ and the complex 1/activator/AlMe₃ systems also showed moderate activities of around 3 × 10³ (g of polymer)/(molLn h) and cis-1,4 selectivities of around 88% in the IP polymerization, affording the cis-1,4-PIPs with lower molecular weights and broader molecular weight distributions (Table 2, entries 1–6). When the IP polymerization catalyzed by the complex 3/A/Al/iBu₃ system was carried out at –20 °C, a PIP with higher cis-1,4 selectivity (>95%), a heavier molecular weight (Mₙ = 350,000 g/mol), and a narrower molecular weight distribution (Mₘ/Mₙ = 1.83) could be obtained, as shown by the ¹H and ¹³C NMR analysis (Table 2, entry 12). It is noteworthy that the complex 3 exhibited high activities of up to 6.8 × 10⁴ (g of polymer)/(molLn h) when the temperature increased to 70 °C (Table 2, entry 14). Only 0.5 h was needed to completely convert 500 equiv of monomer, producing a moderate molecular weight for CPIP (cis-1,4 selectivity of 85%, Mₙ = 200,000 g/mol) with a moderate molecular weight distribution (Mₘ/Mₙ = 3.31).
The resulting PIPs all showed good solubilities in THF and CHCl₃. The ¹H NMR spectra of the PIPs obtained by the complex 1–3/activator/AlR₃ systems in CDCl₃ indicated the main 1,4-microstructure and a trace amount of a 3,4-microstructure. The ¹³C NMR spectra showed diagnostic signals for a main cis-1,4 configuration (δ of 23.4, 26.4, 32.2, 125.0 and 135.2 ppm; cis-1,4-PIP selectivity of >90%) and a small amount of 3,4-configuration (δ of 18.6, 26.4, 32.2, 125.0 and 135.2 ppm) with or without a trace amount of trans-1,4-configuration (δ of 15.9, 26.4, 32.2, 125.0 and 135.2 ppm; Figure 2). GPC curves revealed that these PIPs had moderate to heavy molecular weights in the range of 77,000–710,000 g/mol and bimodal molecular weight distributions (Mₘ/Mₜ = 2.0–4.5) similar to natural rubber. The DSC curves of the resulting cis-1,4-PIPs showed the glass transition temperature in the range of −58 to −65 °C, consistent with the thermoplastic character of the CPIP (see Supplementary Materials).
4. Conclusions

In summary, the three pincer-type monoanionic tridentate \( C_2 \)-symmetric BOXMI-H-ligated rare-earth metal dialkyl complexes 1–3 have been easily synthesized in moderate yields via one-pot acid–base reaction by using the rare-earth metal tris(trimethylsilylmethyl) complexes with the readily available BOXMI-H ligand. The X-ray diffractions demonstrated that the complexes 1 and 2 are isomorphous and isostructural and that each of them adopt a distorted trigonal bipyramidal configuration. Activated by the activators ([Ph\( \text{C}_3 \)])\([\text{B} (\text{C}_6 \text{F}_5)_4 \]) (A), [PhMe\( \text{NH}_2 \)]\([\text{B} (\text{C}_6 \text{F}_5)_4 \]) (B) and B(C\( \text{6} \)F\( \text{5} \))\(_3 \) (C) and Al\( \text{R}_3 \) (R = Me, Et and \( \text{i} \)Bu) in toluene, these pincer-type BOXMI-ligated complexes 1–3 exhibited high activities of up to \( 6.8 \times 10^4 \) (g of polymer)/(mol\( \text{Ln} \) h) and high cis-1,4 selectivities of up to 97% in the polymerization of isoprene, affording cis-1,4-PIPs with heavy molecular weights (\( M_n \) of up to 710,000 g/mol) and bimodal molecular weight distributions (\( M_w/M_n \) = 2.0–4.5). In comparison with the trans-1,4-PIPs obtained by the (S,S)-bis(oxazolinylphenyl)amine-ligated rare-earth metal dialkyl complexes [38] and the cis-1,4-PIPs obtained by the 1,3-bis(2-pyridylimino)isoindoline-ligated rare-earth metal dialkyl complexes [39], such results demonstrate that the main body skeleton of the chelating ligand has a more important impact on the catalytic performance of these pincer-type
rare-earth metal dialkyl complexes in the IP polymerization. Moreover, the rare-earth metal dialkyl complexes bearing the pincer-type chelating ligand with the rigid skeleton and the bulky substituents are not good for the cis-1,4-polymerization of IP. These findings will benefit the design of the high-efficiency and selective catalysts, as well as the rapid and precise synthesis of natural rubber. Further studies will be focused on the modification of the chelating ligand to improve the selectivity and/or activity of the rare-earth metal catalytic system in the cis-1,4-polymerization of isoprene.
