EFFICIENT REMOVAL WITHOUT EFFICIENT REGULARITY

Obtaining an efficient bound for the triangle removal lemma is one of the most outstanding open problems of extremal combinatorics. Perhaps the main bottleneck for achieving this goal is that triangle-free graphs can be highly unstructured. For example, triangle-free graphs might have only regular partitions (in the sense of Szemerédi) of tower-type size. And indeed, essentially all the graph properties $\mathcal{P}$ for which removal lemmas with reasonable bounds were obtained, are such that every graph satisfying $\mathcal{P}$ has a small regular partition. So in some sense, a barrier for obtaining an efficient removal lemma for property $\mathcal{P}$ was not having an efficient regularity lemma for graphs satisfying $\mathcal{P}$.

In this paper we consider the property of being induced $C_4$-free, which also suffers from the fact that a graph might satisfy this property but still have only regular partitions of tower-type size. By developing a new approach for this problem we manage to overcome this barrier and thus obtain a merely exponential bound for the induced $C_4$ removal lemma. We thus obtain the first efficient removal lemma that does not rely on an efficient version of the regularity lemma. This is the first substantial progress on a problem raised by Alon in 2001, and more recently by Alon, Conlon and Fox.

1. Introduction

An $n$-vertex graph is $\varepsilon$-far from satisfying a property $\mathcal{P}$ if one should add/delete at least $\varepsilon n^2$ edges in order to turn $G$ into a graph satisfying $\mathcal{P}$. The so-called induced removal lemma of Alon, Fischer, Krivelevich and Szegedy [2] states that for every fixed graph $H$, if an $n$-vertex graph $G$ is $\varepsilon$-far from being induced $H$-free, then $G$ contains at least $n^h/\text{Rem}_H(\varepsilon)$ induced copies of $H$, where $h = |V(H)|$ and $\text{Rem}_H(\varepsilon)$ depends only on $\varepsilon$. The proof

Mathematics Subject Classification (2010): 05C35
of this lemma in [2] supplied extremely weak bounds for Rem$_H(\varepsilon)$, which were later improved by Conlon and Fox [9]. However, even these improved bounds are of tower-type$^1$.

Alon [1] asked for which graphs $H$ we have Rem$_H(\varepsilon) = \text{poly}(1/\varepsilon)$? That is, for which graphs can we obtain polynomial bounds for the induced removal lemma? This question was addressed by Alon and the second author [5] who resolved this problem for all graphs $H$ except for $P_3$ (the path on 4 vertices) and $C_4$ (the 4-cycle). The former case was recently solved by Alon and Fox [4], who proved that Rem$_{P_3}(\varepsilon) = \text{poly}(1/\varepsilon)$. They further asked to determine if Rem$_{C_4}(\varepsilon) = \text{poly}(1/\varepsilon)$. This problem was also later raised by Conlon and Fox [10].

Prior to this work the best bound for Rem$_{C_4}(\varepsilon)$ was the same tower-type bound that holds for all graphs $H$. As we explain in the next subsection, the reason is that this problem seemed to lie just outside the realm of the known techniques for proving efficient bounds for graph removal lemmas. Our main result in this paper makes the first substantial progress on this problem, by improving the tower-type bound into an exponential one.

**Theorem 1.1.** If an $n$-vertex graph $G$ is $\varepsilon$-far from being induced $C_4$-free, then $G$ contains at least $n^4/2(1/\varepsilon)^c$ induced copies of $C_4$, where $c$ is an absolute constant.

We conjecture that the exponential bound in Theorem 1.1 can be further improved to a polynomial one.

Given a (possibly infinite) family of graphs $\mathcal{F}$, we say that a graph is induced $\mathcal{F}$-free if it is induced $H$-free for every $H \in \mathcal{F}$. Observe that for infinite families $\mathcal{F}$ it is not a priori clear that a graph which is $\varepsilon$-far from being induced $\mathcal{F}$-free should contain any constant size (that might depend on $\varepsilon$) subgraph that is not induced $\mathcal{F}$-free. Such a result was obtained by Alon and the second author [6], who extended the result of [2] by showing that for every family of graphs $\mathcal{F}$, there is a function Rem$_\mathcal{F}(\varepsilon)$, so that if $G$ is $\varepsilon$-far from being induced $\mathcal{F}$-free, then a random subset of Rem$_\mathcal{F}(\varepsilon)$ vertices from $V(G)$ is not induced $\mathcal{F}$-free with probability at least (say$^2$) $2/3$. Needless to say that as in [2], the bounds for Rem$_\mathcal{F}(\varepsilon)$ given by [6] are also (at least) of tower-type.

It is natural to ask if Theorem 1.1 can be extended to properties defined by forbidding a family of graphs $\mathcal{F}$, one of which is $C_4$. The most notable

---

$^1$ We use tower($x$) for a tower of exponents of height $x$, so tower(3) = $2^{2^2}$. The original proof of the induced removal lemma in [2] gave only wowzer-type bounds, where wowzer is the iterated-tower function.

$^2$ It is easy to see that if $\mathcal{F} = \{H\}$, this way of defining Rem$_\mathcal{F}(\varepsilon)$ is equivalent (up to polynomial factors) to the induced removal lemma of [2], as we stated it above.
and natural example is the property of being chordal, which is the property of not containing an induced cycle of length at least 4. Previously, the best bound for this problem was the tower-type bound which follows from the general result of [6]. Here we obtain the following improved bound.

**Theorem 1.2.** There is an absolute constant $c$, such that for every $\varepsilon \in (0, 1)$, for every integer $n$ and for every $n$-vertex graph $G$ which is $\varepsilon$-far from being chordal, there is $4 \leq \ell \leq O(\varepsilon^{-18})$ such that $G$ contains at least $n^{\ell}/2^{(1/\varepsilon)^c}$ induced copies of $C_\ell$.

While Theorem 1.2 asserts that if $G$ is $\varepsilon$-far from being chordal it must contain an induced cycle of length poly$(1/\varepsilon)$, it only implies that a sample of vertices of size $2^{(1/\varepsilon)^c}$ contains an induced cycle with probability at least $2/3$. We do believe, however, that this exponential bound can be further improved to a polynomial one.

It is now natural to ask if Theorem 1.2 can be further extended to an arbitrary family of graphs $\mathcal{F}$, one of which is $C_4$. As our final theorem shows, this is not the case in a very strong sense.

**Theorem 1.3.** For every (decreasing) function $g: (0, 1/2) \rightarrow \mathbb{N}$ there is a family of graphs $\mathcal{F} = \mathcal{F}(g)$ so that $C_4 \in \mathcal{F}$ and yet $\text{Rem}_{\mathcal{F}}^g(\varepsilon) \geq g(\varepsilon)$.

In fact, for every (small enough) $\varepsilon > 0$ and every $n \geq n_0(\varepsilon)$, there is an $n$-vertex graph $G$ which is $\varepsilon$-far from being induced $\mathcal{F}$-free, and yet does not contain an induced copy of any $F \in \mathcal{F}$ on fewer than $g(\varepsilon)$ vertices.

### 1.1. Relation to prior works

In this subsection we would like to explain why in Theorem 1.1 we managed to overcome for the first time a natural barrier, which was the main reason why one could not derive Theorem 1.1 via techniques that were previously used for proving graph removal lemmas. For simplicity we will start by discussing the triangle removal lemma, that is, the special case of the induced removal lemma when $H = K_3$. The original proof of the triangle removal lemma [25] relied on the famous regularity lemma of Szemerédi [26], which is one of the most powerful tools for tackling problems in extremal graph theory. It states that for every $\varepsilon > 0$ there is an $M = M(\varepsilon)$ so that every graph has an $\varepsilon$-regular partition of order at most $M$ (see [24] for the precise definitions related to graph regularity). Since Szemerédi’s proof only established that $M(\varepsilon) \leq \text{tower}(1/\varepsilon^5)$, this approach for proving the triangle removal lemma only gave the very weak bound $\text{Rem}_{K_3}(\varepsilon) \leq \text{tower}(\text{poly}(1/\varepsilon))$. Gowers’ celebrated result [18], which states that $M(\varepsilon) \geq \text{tower}(\text{poly}(1/\varepsilon))$, implies that one cannot get a better bound for $\text{Rem}_{K_3}(\varepsilon)$ via the regularity
lemma. In a major breakthrough, Fox [13] managed to prove the triangle
removal lemma while avoiding Szemerédi’s version of the regularity lemma,
thus showing that $\text{Rem}_{K_3}(\varepsilon) \leq \text{tower}(O(\log 1/\varepsilon))$. A different formulation of
his proof was later given in [10] and [21]. The latter proof shows that Fox’s
result can be derived from a variant of the regularity lemma. Unfortunately,
it was shown in [21] that this variant of the regularity lemma must also pro-
duce partitions of tower-type size. Hence, this approach does not seem to
allow one to prove (say) exponential bounds for the triangle removal lemma.

Although the best known bounds for the triangle removal lemma are of
tower-type, there are families of graphs $\mathcal{F}$ for which one can prove much bet-
ter (non-tower-type) bounds for $\text{Rem}_{\mathcal{F}}(\varepsilon)$, that is, for the removal lemma of
induced $\mathcal{F}$-freeness. One example is the result of Alon and Fox [4] mentioned
above regarding induced $P_3$-freeness. The main point we would like to make
is that all these improved bounds (save for one case discussed below) were
not obtained by avoiding the regularity lemma. Instead, they still (implicitly
or explicitly) used the regularity lemma, but relied on the fact that induced
$\mathcal{F}$-free graphs have much smaller $\varepsilon$-regular partitions. For example, the re-
sult of Alon and Fox [4] regarding induced $P_3$-freeness can be derived from
the fact that every induced $P_3$-free graph has an $\varepsilon$-regular partition of size
poly(1/\varepsilon). See [14] for a proof of this and other related results.

It is now natural to ask if one can use the above approach in order to
obtain better bounds for the triangle removal lemma. Unfortunately, there
are bipartite versions of Gowers’ [18] lower bound for the regularity lemma,
as well as for the variant of the regularity lemma introduced in [21]. There-
fore, a graph can be triangle-free but still only have regular partitions of
tower-type size. This means that any proof of the triangle removal lemma
that relies on (one of the above versions of) the regularity lemma is bound
to produce tower-type bounds.

With regard to induced $C_4$-freeness, it is easy to see that every split graph
is induced $C_4$-free, where a split graph is a graph whose vertex set can be
partitioned into two sets, one inducing a complete graph and the other an
independent set. This means that if we take a bipartite version of Gowers’
lower bound [18] (or of the one from [21]), and put a complete graph on one
of the vertex sets, we get an induced $C_4$-free graph that has only regular
partitions of tower-type size. In particular, arguments similar to those that
were previously used in order to devise efficient removal lemmas cannot give
better-than-tower-type bounds for this problem.

Summarizing the above discussion, Theorem 1.1 is the first example show-
ing that one can obtain an efficient removal lemma for a property $\mathcal{P}$, even
though graphs satisfying $\mathcal{P}$ might have only regular partitions of tower-type
size. To do this, our proof is the first removal lemma that avoids using the
regularity lemma or one of its variants (save for the example discussed be-
low). We are hopeful that bounds similar to those obtained in Theorem 1.1
can be obtained for removal lemmas of other properties for which the best known bounds are of tower-type, most notably for triangle freeness.

Let us end the discussion by describing the only previous example of a removal lemma that was obtained while avoiding a regularity lemma, and how it differs from Theorem 1.1. In 1984 Erdős [12] (implicitly) conjectured that $k$-colorability has a removal lemma, that is, that if $G$ is $\varepsilon$-far from being $k$-colorable, then a sample of $C_k(\varepsilon)$ vertices from $V(G)$ spans a non-$k$-colorable subgraph with probability at least $2/3$. This was first verified by Rödl and Duke [23] who used the regularity lemma in order to obtain a tower-type bound for $C_k(\varepsilon)$. This tower-type bound was dramatically improved by Goldreich, Goldwasser and Ron [16], who obtained a new proof of this result (as well as for similar partition problems) that avoided the regularity lemma and thus gave a polynomial bound for $C_k(\varepsilon)$. Let us try$^3$ to explain why $k$-colorability differs from triangle-freeness or induced $C_4$-freeness. First, as opposed to these two properties which are local, the partition properties of [16] are global. Perhaps the best way to see this is from the perspective of graph homomorphisms: triangle-freeness means that there is no edge-preserving mapping from the vertices of the triangle to the vertices of $G$, while 3-colorability means that there is such a mapping from the vertices of $G$ to the vertices of the triangle$^4$. The second difference, which is more important for our quantitative investigation here, is that $k$-colorability is defined using global edge counts (i.e. having no edges inside a vertex partition into $k$ sets). This can explain (at least in hindsight), why one does not need any structure theorem in order to handle this property. Instead one can rely on sampling arguments that boil down to estimating various edge densities (this is not to say that devising such proofs is an easy task!). It appears that arguments of this sort cannot be used to prove removal lemmas for local properties such as triangle freeness or induced $C_4$-freeness.

1.2. Paper overview

The main idea of the proof is to show that (very roughly speaking) every induced $C_4$-free graph is a split graph. To be more precise, every$^5$ induced $C_4$-free graph is close to being a union of an independent set and few cliques, so that the bipartite graphs between these cliques are highly structured. Note that we have no guarantee on the structure of the bipartite graph connecting

---

$^3$ See also Subsection 8.3.2 of Goldreich’s upcoming book [15] for a similar attempt.

$^4$ In the language of graph limits, this is the distinction between left and right homomorphisms, see [20].

$^5$ It is known [22] that most induced $C_4$-free graphs are split graphs. We stress that in our setting we have to deal with every induced $C_4$-free graph, not just typical ones!
the independent set and the cliques\textsuperscript{6}. Towards this goal, in Section 2 we describe some preliminary lemmas, mostly regarding the structure of bipartite graphs that do not contain an induced matching of size 2. In Section 3 we give the main partial structure theorem, stated as Lemma 3.6. In the course of the proof we will make a surprising application of one of the main results of Goldreich, Goldwasser and Ron [16]. In Section 4 we give the proofs of Theorems 1.1 and 1.2. We will make use of the structure theorem from Section 3 but will also have to deal with the (unavoidable) unstructured part of the graph. This will be done in Lemma 4.1. Finally, in Section 5, we give the proof of Theorem 1.3. We will make no effort to optimize the constant \( c \) appearing in Theorems 1.1 and 1.2.

2. Forbidding an induced 2-matching

Our goal in this section is to introduce several definitions and prove Lemma 2.4 stated below, regarding graphs not containing induced matchings of size 2 of a specific type, which we now formally define. Let \( G \) be a graph and let \( X,Y \subseteq V(G) \) be disjoint sets of vertices. An \textit{induced copy of} \( M_2 \) in \( (X,Y) \) is an (unordered) quadruple \( x,x',y,y' \) such that \( x,x' \in X, y,y' \in Y, \{x,y\},\{x',y'\} \in E(G) \) and \( \{x,y'\},\{x',y\} \notin E(G) \). We say that \( (X,Y) \) is \textit{induced} \( M_2 \)-free if it does not contain induced copies of \( M_2 \) as above. Observe that if \( X \) and \( Y \) are cliques then \( G[X \cup Y] \) is induced \( C_4 \)-free if and only if \( (X,Y) \) is induced \( M_2 \)-free. For \( x \in X \), we denote \( N_Y(x) = \{y \in Y : \{x,y\} \in E(G)\} \).

**Claim 2.1.** \( (X,Y) \) is induced \( M_2 \)-free\textsuperscript{7} if and only if there is an enumeration \( x_1,\ldots,x_m \) of the elements of \( X \) such that \( N_Y(x_i) \subseteq N_Y(x_j) \) for every \( 1 \leq i < j \leq m \).

**Proof.** Observe that \( (X,Y) \) contains an induced \( M_2 \) if and only if there are \( x,x' \in X \) for which there exist \( y \in N_Y(x) \setminus N_Y(x') \) and \( y' \in N_Y(x') \setminus N_Y(x) \). Therefore, \( (X,Y) \) is induced \( M_2 \)-free if and only if for every \( x,x' \in X \) it holds that either \( N_Y(x) \subseteq N_Y(x') \) or \( N_Y(x') \subseteq N_Y(x) \). Consider the poset on \( X \) in which \( x \) precedes \( x' \) if and only if \( N_Y(x) \subseteq N_Y(x') \). This poset is a linear ordering. Enumerate the elements of \( X \) from minimal to maximal to get the required enumeration.

\textsuperscript{6} This unstructured part is unavoidable due to the example we mentioned earlier of putting Gowers’ construction between a clique and an independent set.

\textsuperscript{7} Let us mention that \textit{half-graphs} are a special case of induced \( M_2 \)-free bipartite graphs. A half-graph has \( 2n \) vertices \( x_1,\ldots,x_n,y_1,\ldots,y_n \), and \( x_i \) is adjacent to \( y_j \) if and only if \( i \geq j \).
For a pair of disjoint vertex-sets $X, Y$, we say that $(X, Y)$ is.homoge-
neous if the bipartite graph between $X$ and $Y$ is either complete or empty.
Throughout the paper, and in particular in the following lemma, we will
avoid floor/ceiling signs, by assuming that the number of vertices in the
vertex-set under consideration is divisible by some small integers (ultimately
these integers would depend only on the parameter $\varepsilon$). In what follows, when
considering partitions of a set, we allow partition classes to be empty.

**Lemma 2.2.** If $(X, Y)$ is induced $M_2$-free, then for every integer $r \geq 1$ there
are partitions $X = X_1 \cup \cdots \cup X_r$ and $Y = Y_1 \cup \cdots \cup Y_{r+1}$ such that $|X_i| = \frac{|X|}{r}$
for every $1 \leq i \leq r$, and $(X_i, Y_j)$ is homogeneous for every $1 \leq i \leq r$ and
$1 \leq j \leq r+1$ satisfying $i \neq j$.

**Proof.** Let $x_1, \ldots, x_m$ be the enumeration of the elements of $X$ from Claim
2.1. For $1 \leq i \leq r$ define $X_i = \{x_j : \frac{(i-1)m}{r} < j \leq \frac{im}{r}\}$. Let now $y_1, \ldots, y_n$
be an enumeration of the elements of $Y$ with the property that for every
$x \in X$, the set $N_Y(x)$ is a “prefix” of the enumeration, that is, so
that $N_Y(x) = \{y_1, \ldots, y_k\}$ for some $0 \leq k \leq n$. Define $Y_1 = N_Y(x_{\lfloor m/r \rfloor})$, $Y_i = N_Y(x_{\lfloor im/r \rfloor}) \setminus N_Y(x_{\lfloor (i-1)m/r \rfloor})$ for $i = 2, \ldots, r$ and $Y_{r+1} = Y \setminus N_Y(x_m)$.

It remains to show that $(X_i, Y_j)$ is homogeneous for every $i \neq j$. Assume
first that $i < j$. Then for every $x \in X_i$ we have $N_Y(x) \subseteq N_Y(x_{\lfloor im/r \rfloor}) \subseteq N_Y(x_{\lfloor (j-1)m/r \rfloor})$. By the definition of $Y_j$ we have $Y_j \cap N_Y(x_{\lfloor (j-1)m/r \rfloor}) = \emptyset$. Thus, $Y_j \cap N_Y(x) = \emptyset$ for every $x \in X_i$, implying that the bipartite graph
$(X_i, Y_j)$ is empty. Now assume that $i > j$. For every $x \in X_i$ we have
$N_Y(x_{\lfloor jm/r \rfloor}) \subseteq N_Y(x_{\lfloor (i-1)m/r \rfloor}) \subseteq N_Y(x)$. By the definition of $Y_j$ we have
$Y_j \subseteq N_Y(x_{\lfloor jm/r \rfloor})$. Thus, $Y_j \subseteq N_Y(x)$ for every $x \in X_i$, implying that the
bipartite graph $(X_i, Y_j)$ is complete. $\blacksquare$

For two partitions $P_1, P_2$ of the same set, we say that $P_2$ is a refinement of
$P_1$ if every part of $P_2$ is contained in one of the parts of $P_1$. A vertex partition
$P$ of an $n$-vertex graph $G$ is called $\delta$-homogeneous if the sum of $|U||V|$ over
all non-homogeneous unordered distinct pairs $U, V \in P$ is at most $\delta n^2$. Note
that if a $\delta$-homogeneous partition $P$ refines a partition $\{X_1, \ldots, X_k\}$ such
that each $X_i$ is either a clique or an independent set, then every refinement
of $P$ is also $\delta$-homogeneous.

**Lemma 2.3.** Let $\delta \in (0, 1/2)$, let $G$ be an $n$-vertex graph and let $V(G) =
X_1 \cup \cdots \cup X_k$ be a partition such that $X_1, \ldots, X_k$ are cliques and $(X_i, X_j)$
is induced $M_2$-free for every $1 \leq i < j \leq k$. Then there is a $\delta$-homogeneous
partition which refines $\{X_1, \ldots, X_k\}$ and has at most $k(2/\delta)^k$ parts.

**Proof.** For every $1 \leq i < j \leq k$, we apply Lemma 2.2 to $(X_i, X_j)$ with param-
eter $r = \lceil 1/\delta \rceil$ to get partitions $P_{i,j}$ of $X_i$ and $P_{j,i}$ of $X_j$, $P_{i,j} = \{X_{i,j}^1, \ldots, X_{i,j}^r\}$,
\( \mathcal{P}_{j,i} = \{X_{j,i}^1, \ldots, X_{j,i}^{r+1}\} \), such that \( |X_{i,j,p}^p| = \frac{|X_{i,j}|}{r} \) for every \( 1 \leq p \leq r \), and \((X_{i,j,p}^p, X_{j,i}^q)\) is homogeneous for every \( p \neq q \). Note that

\[
(1) \quad \sum_{p=1}^{r} |X_{j,i}^p||X_{i,j}^p| = \sum_{p=1}^{r} \frac{1}{r} |X_i||X_{j,i}^p| \leq \frac{1}{r} |X_i||X_j| \leq \delta |X_i||X_j|.
\]

For every \( i = 1, \ldots, k \), define \( \mathcal{P}_i \) to be the common refinement of the partitions \((\mathcal{P}_{i,j})_{1 \leq j < k, j \neq i}\). We have \( |\mathcal{P}_i| \leq (r+1)^{k-1} \leq (\frac{1}{\delta} + 2)^{k-1} \leq (2/\delta)^k \). The partition \( \mathcal{P} := \bigcup_{i=1}^{k} \mathcal{P}_i \) refines \( \{X_1, \ldots, X_k\} \) and has at most \( k (2/\delta)^k \) parts. For every \( U, V \in \mathcal{P} \), if \((U, V)\) is not homogeneous, then there are \( 1 \leq i < j \leq k \) and \( 1 \leq p \leq r \) such that \( U \subseteq X_{i,j}^p \) and \( V \subseteq X_{i,j}^p \). This follows from the fact that \( X_1, \ldots, X_k \) are cliques and the property of the partitions \((\mathcal{P}_{i,j})_{1 \leq i \neq j \leq k}\). By (1), we have

\[
\sum_{1 \leq i < j \leq k} \sum_{p=1}^{r} |X_{i,j}^p||X_{j,i}^p| \leq \delta \sum_{1 \leq i < j \leq k} |X_i||X_j| \leq \delta n^2,
\]

implying that \( \mathcal{P} \) is \( \delta \)-homogeneous, as required.

We are ready to prove the main lemma of this section. One important idea we will employ here is that of obtaining a partition \( \mathcal{P} \) and then a refinement \( \mathcal{Q} \) of \( \mathcal{P} \) with somewhat better parameters, and then using some parts of \( \mathcal{Q} \) in order to approximate \( \mathcal{P} \). This idea goes back to the original proof of the induced removal lemma in [2].

**Lemma 2.4.** Let \( \delta \in (0, 1/2) \), let \( G \) be an \( n \)-vertex graph and let \( V(G) = X_1 \cup \cdots \cup X_k \) be a partition such that \( X_1, \ldots, X_k \) are cliques and \((X_i, X_j)\) is induced \( M_2 \)-free for every \( 1 \leq i < j \leq k \). Then there is a set \( Z \subseteq V(G) \) of size \( |Z| < \delta n \), a partition \( V(G) \setminus Z = Q_1 \cup \cdots \cup Q_q \) which refines \( \{X_1 \setminus Z, \ldots, X_k \setminus Z\} \) and subsets \( W_i \subseteq Q_i \) such that the following hold.

1. The sum of \( |Q_i||Q_j| \) over all non-homogeneous pairs \((Q_i, Q_j)\), \( 1 \leq i < j \leq q \), is at most \( \delta n^2 \).
2. \( |W_i| \geq (\delta/2k) 10k^2 n \) for every \( 1 \leq i \leq q \) and \((W_i, W_j)\) is homogeneous for every \( 1 \leq i < j \leq q \).

**Proof.** The assertion is trivial for \( k = 1 \) so we assume that \( k \geq 2 \). Apply Lemma 2.3 to \( G \) with parameter \( \delta \) to obtain a \( \delta \)-homogeneous partition \( \mathcal{P} \) which refines \( \{X_1, \ldots, X_k\} \). Let us define \( \mathcal{Q} = \{U \in \mathcal{P} : |U| \geq \frac{\delta n}{|\mathcal{P}|}\} \) and write \( \mathcal{Q} = \{Q_1, \ldots, Q_q\} \). Then Item 1 holds since \( \mathcal{P} \) is \( \delta \)-homogeneous. Setting \( Z = \bigcup_{U \in \mathcal{P}\setminus \mathcal{Q}} U \), notice that \( \mathcal{Q} \) refines \( \{X_1 \setminus Z, \ldots, X_k \setminus Z\} \) and that \( |Z| < |\mathcal{P}| \cdot \frac{\delta n}{|\mathcal{P}|} = \delta n \). Apply Lemma 2.3 to \( G[V(G) \setminus Z] \), with the partition \( \{X_1 \setminus Z, \ldots, X_k \setminus Z\} \).
(in place of \( \{X_1, \ldots, X_k\} \)), and with parameter \( \delta' := \frac{\delta^2}{4|P|^4} \). The lemma gives a \( \delta' \)-homogeneous partition \( V \) with at most \( k(8|P|^4/\delta^2)^k \) parts. Let \( W \) be the common refinement of \( Q \) and \( V \). Note that \( W \) is \( \delta' \)-homogeneous as a refinement of \( V \), since \( V \) is \( \delta' \)-homogeneous and refines \( \{X_1 \setminus Z, \ldots, X_k \setminus Z\} \), and \( X_1 \setminus Z, \ldots, X_k \setminus Z \) are cliques. Moreover, we have

\[
|W| \leq |Q| \cdot |V| \leq |P| \cdot k(8|P|^4/\delta^2)^k.
\]

For each \( 1 \leq i \leq q \), define \( W_i = \{W \in W : W \subseteq Q_i\} \), choose a vertex \( w_i \in Q_i \) uniformly at random and let \( W_i \in W_i \) be such that \( w_i \in W_i \). We will show that with positive probability, the sets \( W_1, \ldots, W_q \) satisfy the statement in Item 2. For \( 1 \leq i \leq q \), the probability that \( |W_i| < \frac{|Q_i|}{2q|W|} \) is smaller than

\[
\sum \frac{|W||W'|}{|Q_i||Q_j|} \leq \frac{4|P|^2}{\delta^2n^2} \sum |W||W'| \leq \frac{4|P|^2}{\delta^2n^2} \cdot \delta' \cdot n^2 = \frac{1}{|P|^2},
\]

where the sums are taken over all non-homogeneous pairs \( (W_i, W_j) \in W_i \times W_j \), the first inequality uses \( |Q_i|, |Q_j| \geq \frac{\delta n}{2|P|^4} \) and the second the fact that \( W \) is \( \delta' \)-homogeneous. By the union bound, with probability at least \( 1 - \left(\frac{q^2}{2}\right)^{1/2} \geq 1 - \left(\frac{|P|}{2}\right)^{1/2} > \frac{1}{2} \), all pairs \( (W_i, W_j) \) are homogeneous. We conclude that Item 2 holds with positive probability.

It is worth mentioning that the bounds in the above lemma are the sole reason why our bound in Theorem 1.1 is exponential rather than polynomial.
3. A partial structure theorem for $C_4$-free graphs

Our main goal in this section is to prove Lemma 3.6 stated below, which gives an approximate partial structure theorem for induced $C_4$-free graphs. The “approximation” will be due to the fact that the graph will only be close to having a certain nice structure, while the “partial” will be since there will be a (possibly) big part of the graph about which we will have no control. As we discussed in Section 1, this partialness is unavoidable as evidenced by split graphs.

In addition to the lemmas from the previous section, we will also need the following theorems of Goldreich, Goldwasser and Ron [16] and of Gyárfás, Hubenko and Solymosi [19]. In both cases, $\omega(G)$ denotes maximum size of a clique in $G$.

**Theorem 3.1 ([16], Theorem 7.1).** For every $\varepsilon \in (0,1)$ there is $q_{3,1}(\varepsilon) = O(\varepsilon^{-5})$ with the following property. Let $\rho \in (0,1)$ be such that $\varepsilon < \rho^2 / 2$ and let $G$ be a graph which is $\varepsilon$-far from satisfying $\omega(G) \geq \rho n$. Suppose $q \geq q_{3,1}(\varepsilon)$ and let $Q \subseteq V(G)$ be a randomly chosen set of $q$ vertices of $G$. Then with probability at least $\frac{2}{3}$ we have $\omega(G[Q]) < (\rho - \frac{\varepsilon}{2})q$.

**Theorem 3.2 ([19]).** Every induced $C_4$-free graph $G$ with $n$ vertices and at least $\alpha n^2$ edges satisfies $\omega(G) \geq 0.4\alpha^2 n$.

Let us now derive the following important corollary of the above two theorems. For a set $X \subseteq V(G)$ with at least 2 vertices, define $d(X) = e(X)/\binom{|X|}{2}$, where $e(X)$ is the number of edges of $G$ with both endpoints in $X$.

**Lemma 3.3.** Let $\alpha \in (0,1/2)$ and let $G$ be a graph on $n$ vertices with at least $\alpha n^2$ edges. Then for every $\beta \in (0,1)$, either $G$ contains $\Omega(\alpha^{80}\beta^{20}n^4)$ induced copies of $C_4$ or there is a set $X \subseteq V(G)$ with $|X| \geq 0.1\alpha^2 n$ and $d(X) \geq 1 - \beta$.

In the proof of Lemma 3.3 we need the following simple fact, which is proved by a standard application of the second moment method (see e.g. [7]). We first prove Claim 3.4 and then present the proof of Lemma 3.3.

**Claim 3.4.** Let $\alpha \in (0,1/2)$ and let $G$ be a graph with $n$ vertices and at least $\alpha n^2$ edges. Then for every $r \geq \frac{240}{\alpha}$, a randomly chosen set $R \subseteq \binom{V(G)}{r}$ satisfies $e(R) \geq \frac{\alpha \beta}{2} r^2$ with probability at least $\frac{2}{3}$.

**Proof.** Let $\eta \in (0,1)$ be such that $G$ has exactly $\eta n^2$ edges, noting that $\eta \geq \alpha$. We consider the random variable $e(R)$. For each $e \in E(G)$, let $I_e$ be the
indicator of the event $e \subseteq R$. Then $e(R) = \sum_{e \in E(G)} I_e$. Note that $\mathbb{P}[e \subseteq R] = \frac{r(r-1)}{n(n-1)}$, so by linearity of expectation we have $\mathbb{E}[e(R)] = e(G) \cdot \frac{r(r-1)}{n(n-1)} \geq e(G) \cdot \frac{3}{4} \cdot \frac{r^2}{n^2} = \frac{3n}{4} r^2$. Now let us estimate the variance of $e(R)$. We have

$$\text{Var}[e(R)] = \sum_{e \in E(G)} \mathbb{P}[e \subseteq R] + \sum_{e, e' \in E(G)} \left( \mathbb{P}[e, e' \subseteq R] - \mathbb{P}[e \subseteq R] \cdot \mathbb{P}[e' \subseteq R] \right),$$

where the second sum is over all ordered pairs $e, e'$ of distinct edges. If $e, e'$ are disjoint, then $\mathbb{P}[e, e' \subseteq R] = \frac{r(r-1)(r-2)(r-3)}{n(n-1)(n-2)(n-3)} \leq \left( \frac{r}{n} \right)^4$, and $\mathbb{P}[e \subseteq R] \cdot \mathbb{P}[e' \subseteq R] = \left( \frac{r(r-1)}{n(n-1)} \right)^2 \geq \frac{r^2(r-1)^2}{n^4} \geq \frac{r^4 - 2r^3}{n^4}$. So the term corresponding to the pair $e, e'$ in the above sum is at most $\frac{r^4 - 2r^3}{n^4} = \frac{2r^3}{n^4}$. Since there are at most $e(G)^2 = \eta^2 n^4$ pairs of edges $e, e'$ altogether, the pairs in which $e, e'$ are disjoint contribute at most $\eta^2 n^4 \cdot \frac{2r^3}{n^4} = 2\eta r^3$ to the above sum.

If $e, e'$ intersect (namely, have a vertex in common), then $\mathbb{P}[e, e' \subseteq R] = \frac{r(r-1)(r-2)}{n(n-1)(n-2)} \leq \frac{(r/n)^3}{n^4}$. Since there are at most $e(G) \cdot 2n$ pairs of intersecting edges $e, e'$, these pairs contribute at most $e(G) \cdot 2n \cdot \frac{r^3}{n^4} = 2\eta r^3$. Altogether, we have

$$\text{Var}[e(R)] \leq \sum_{e \in E(G)} \mathbb{P}[e \subseteq R] + 2\eta^2 r^3 + 2\eta r^3 \leq \eta^2 r^3 + 2\eta^2 r^3 + 2\eta^3 \leq 5\eta r^3,$$

where in the second inequality we used the fact that $\sum_{e \in E(G)} \mathbb{P}[e \subseteq R] = \mathbb{E}[e(R)] \leq e(G) \cdot \left( \frac{r}{n} \right)^2 = \eta^2$. By Chebyshev’s inequality (see e.g. [7]), we have

$$\mathbb{P} \left[ |e(R) - \mathbb{E}[e(R)]| > \frac{\eta}{4} r^2 \right] \leq \frac{\text{Var}[e(R)]}{\left( \frac{\eta}{16} \right)^2 r^4} \leq \frac{5\eta^3}{\frac{\eta^2}{16} r^4} = \frac{80}{\eta r} \leq \frac{80}{\alpha r} \leq \frac{1}{3},$$

where in the last inequality we used our choice of $r$. Finally, notice that if $|e(R) - \mathbb{E}[e(R)]| \leq \frac{\eta}{4} r^2$, then $e(R) \geq \mathbb{E}[e(R)] - \frac{\eta}{4} r^2 \geq \frac{3n}{4} r^2 - \frac{\eta}{4} r^2 = \frac{2r^2}{4} \geq \alpha r^2$, as required.

**Proof of Lemma 3.3** Set $\rho = 0.1\alpha^2$, $\epsilon = \alpha^2 \beta = \frac{\alpha^4 \beta}{400}$ and $r = \max\{q_{3.1}(\epsilon), \frac{2400}{\alpha}\}$. By Theorem 3.1 we have $r = O(\alpha^{-20} \beta^{-5})$. We assume that there is no $X \subseteq V(G)$ with $|X| \geq 0.1\alpha^2 n$ and $d(X) \geq 1 - \beta$, and prove that $G$ contains $\Omega(\alpha^{80} \beta^{20} n^4)$ induced copies of $C_4$. Let $X \subseteq V(G)$ be such that $|X| \geq \rho n$. Since $d(X) < 1 - \beta$, we have $\left( \frac{|X|}{2} \right) - e(X) > \beta \left( \frac{|X|}{2} \right) \geq \beta |X|^2/4 \geq \frac{\alpha^2 \beta}{4} n^2 = \epsilon n^2$. This shows that $G$ is $\epsilon$-far from containing a clique of size $\rho n$ or larger. By our choice of $r$ via Theorem 3.1, a random sample $R$ of $r$ vertices of $G$ satisfies $\omega(G[R]) < (\rho - \frac{\epsilon}{2}) r < 0.1\alpha^2 r$ with probability at least $\frac{2}{3}$. By Claim
3.4, we also have \( e(R) \geq \frac{9}{2}r^2 \) with probability at least \( \frac{2}{3} \). So with probability at least \( \frac{1}{3} \) we have both \( \omega(G[R]) < 0.1\alpha^2r \) and \( e(R) \geq \frac{9}{2}r^2 \). If both events happen, then \( G[R] \) must contain an induced copy of \( C_4 \), by Theorem 3.2. We conclude that \( G \) contains at least \( \frac{1}{3}(\frac{n}{r})/(\binom{n}{4}-\binom{\frac{n}{r}}{4}) = \Omega(\alpha^{80}\beta^2n^4) \) induced copies of \( C_4 \).

The last ingredient we need is the following result of Alon, Fischer and Newman [3]. For a pair of disjoint vertex sets \( X,Y \), we say that \( (X,Y) \) is \( \varepsilon \)-far from being induced \( M_2 \)-free if one has to add/delete at least \( \varepsilon|X||Y| \) of the edges between \( X \) and \( Y \) to make \( (X,Y) \) induced \( M_2 \)-free.

**Lemma 3.5 ([3]).** There is an absolute constant \( d \) such that the following holds. If \( (X,Y) \) is \( \varepsilon \)-far from being induced \( M_2 \)-free, then \( (X,Y) \) contains at least \( \varepsilon^d|X|^2|Y|^2 \) induced copies of \( M_2 \).

We can clearly assume that \( d \geq 1 \) in the above lemma, and will do so in what follows. The following is the key lemma of this section. Note that it gives us a lot of information about \( G[Y] \) and \( G[X_1 \cup \cdots \cup X_k] \) but no information about the bipartite graph connecting \( X_1 \cup \cdots \cup X_k \) and \( Y \).

**Lemma 3.6.** There is an absolute constant \( c_0 > 0 \), such that for every \( \alpha, \gamma \in (0,1/2) \), every \( n \)-vertex graph \( G \) either contains \( \Omega(\alpha^{c_0}\gamma^{c_0}n^4) \) induced copies of \( C_4 \), or admits a vertex partition \( V(G) = X_1 \cup \cdots \cup X_k \cup Y \) with the following properties.

1. \( e(Y) < \alpha n^2 \).
2. \( |X_i| \geq 0.1\alpha^3n \) and \( d(X_i) \geq 1 - \gamma \) for every \( 1 \leq i \leq k \).
3. For every \( 1 \leq i < j \leq k \), the pair \( (X_i, X_j) \) is \( \gamma \)-close (i.e. not \( \gamma \)-far) to being induced \( M_2 \)-free.

**Proof.** We prove the lemma with \( c_0 = \max(84,20d) \), where \( d \) is the constant from Lemma 3.5. We inductively define two sequences of sets, \( (V_i)_{i \geq 0} \) and \( (X_i)_{i \geq 1} \). Set \( V_0 = V(G) \). At the \( i \)'th step (starting from \( i = 0 \)), if \( e(V_i) < \alpha n^2 \), then we stop. Note that if we did not stop, then \( |V_i| \geq \alpha^{1/2}n > \alpha n \). If \( e(V_i) \geq \alpha n^2 \), then by Lemma 3.3, applied to \( G[V_i] \) with parameters \( \alpha \) and \( \beta = 0.25\gamma^d \), either \( G[V_i] \) contains \( \Omega(\alpha^{80}\gamma^{20d}|V_i|^4) \geq \Omega(\alpha^{84}\gamma^{20d}n^4) \) induced copies of \( C_4 \) or there is \( X_{i+1} \subseteq V_i \) with \( |X_{i+1}| \geq 0.1\alpha^2|V_i| \geq 0.1\alpha^3n \) and \( d(X_i) \geq 1 - 0.25\gamma^d \). If the former case happens, then the assertion of the lemma holds, so we may assume that the latter case happens, in which case we set \( V_{i+1} = V_i \setminus X_{i+1} \) and continue. Suppose that this process stops at the \( k \)'th step for some \( k \geq 0 \). Set \( Y = V_k \). We clearly have \( V(G) = X_1 \cup \cdots \cup X_k \cup Y \). For every \( 1 \leq i \leq k \) we have \( |X_i| \geq 0.1\alpha^3n \) and \( d(X_i) \geq 1 - 0.25\gamma^d \geq 1 - \gamma \). Since the process stopped at the \( k \)'th step, we must have \( e(Y) = e(V_k) < \alpha n^2 \).
To finish the proof, we show that if Item 3 in the lemma does not hold, then $G$ contains at least $0.5 \cdot 10^{-4} \alpha^{12} \gamma^d n^4$ induced copies of $C_4$. Assume that for some $1 \leq i < j \leq k$, the pair $(X_i, X_j)$ is $\gamma$-far from being induced $M_2$-free. By Lemma 3.5, $(X_i, X_j)$ contains at least $\gamma^d |X_i|^2 |X_j|^2$ induced copies of $M_2$. Let $(x_i, x_i', x_j, x_j')$ be such a copy, where $x_i, x_i' \in X_i$ and $x_j, x_j' \in X_j$. If $\{x_i, x_i', x_j, x_j'\} \in E(G)$, then $x_i, x_i', x_j, x_j'$ span an induced copy of $C_4$. Since $d(X_i), d(X_j) \geq 1 - 0.25 \gamma^d$, there are at most $0.5 \gamma^d |X_i|^2 |X_j|^2$ quadruples of distinct vertices $(x_i, x_i', x_j, x_j') \in X_i \times X_i \times X_j \times X_j$ for which either $\{x_i, x_i'\} \notin E(G)$ or $\{x_j, x_j'\} \notin E(G)$. Thus, $G$ contains at least $0.5 \gamma^d |X_i|^2 |X_j|^2 \geq 0.5 \cdot 10^{-4} \alpha^{12} \gamma^d n^4$ induced copies of $C_4$.

We finish this section with the following corollary of the above structure theorem, which will be more convenient to use when proving Theorems 1.1 and 1.2 in the next section.

**Lemma 3.7.** There is an absolute constant $c_0 > 0$ such that for every $\alpha, \gamma \in (0, 1/2)$, every $n$-vertex graph $G$ either contains $\Omega(\alpha^{c_0} \gamma^{c_0} n^4)$ induced copies of $C_4$ or there is a graph $G'$ on $V(G)$, a partition $V(G) = X_1 \cup \cdots \cup X_k \cup Y$, where $0 \leq k \leq 10 \alpha^{-3}$, a subset $Z \subseteq X := X_1 \cup \cdots \cup X_k$, a partition $X \setminus Z = Q_1 \cup \cdots \cup Q_q$ which refines $\{X_1 \setminus Z, \ldots, X_k \setminus Z\}$, and subsets $W_i \subseteq Q_i$ such that:

1. $G'[X_i \setminus Z]$ is a clique for every $1 \leq i \leq k$, and $G'[Y]$ is an independent set.
2. $|Z| < \alpha n$ and every $z \in Z$ is an isolated vertex in $G'$.
3. In $G'$, the sum of $|Q_i||Q_j|$ over all non-homogeneous pairs $(Q_i, Q_j)$, $1 \leq i < j \leq q$, is at most $\alpha n^2$.
4. $(W_i, W_j)$ is homogeneous in $G'$ for every $1 \leq i < j \leq q$ and $|W_i| \geq \min\left(\frac{(\alpha/20)(20000\alpha^{-6})}{X} \right)$ for every $1 \leq i \leq q$.
5. $|E(G') \Delta E(G)| < (2\alpha + \gamma)n^2$ and $|E(G'[X \setminus Z]) \Delta E(G[X \setminus Z])| < \gamma n^2$.

**Proof.** The constant $c_0$ in this lemma is the same as in Lemma 3.6. Apply Lemma 3.6 to $G$ with the given $\alpha$ and $\gamma$. If $G$ contains $\Omega(\alpha^{c_0} \gamma^{c_0} n^4)$ induced copies of $C_4$, then the assertion of the lemma holds, and otherwise let $X_1, \ldots, X_k, Y$ be as in the statement of Lemma 3.6. Note that $k \leq 10 \alpha^{-3}$ since $|X_i| \geq \alpha n^3 n$ for every $1 \leq i \leq k$. Let $G''$ be the graph obtained from $G$ by making $Y$ an independent set, making $X_1, \ldots, X_k$ cliques and making $(X_i, X_j)$ induced $M_2$-free for every $1 \leq i < j \leq k$. By Lemma 3.6 we have $|E(G''[Y]) \Delta E(G[Y])| < \alpha n^2$ and $|E(G''[X]) \Delta E(G[X])| < \gamma \sum_{i=1}^k |X_i| + \gamma \sum_{i < j} |X_i||X_j| < \gamma n^2$. We now apply Lemma 2.4 to $G''[X]$ with parameter $\delta = \alpha$ (and with respect to the partition $\{X_1, \ldots, X_k\}$) and obtain a subset $Z \subseteq X$ of size $|Z| < \alpha|X| \leq \alpha n$, a partition $X \setminus Z = Q_1 \cup \cdots \cup Q_q$ which refines $\{X_1 \setminus Z, \ldots, X_k \setminus Z\}$, and subsets $W_i \subseteq Q_i$. 

such that \( |W_i| \geq (\alpha/2k)^{10k^2} |X| \geq (\alpha^4/20)^{1000\alpha^{-6}} |X| \geq (\alpha/20)^{4000\alpha^{-6}} |X| \) for every \( 1 \leq i \leq q \).

Let \( G' \) be the graph obtained from \( G'' \) by making every \( z \in Z \) an isolated vertex. Then Item 2 is satisfied. The second part of Item 5 holds because \( G'[X \setminus Z] = G''[X \setminus Z] \) and \( |E(G''[X]) \triangle E(G[X])| < \gamma n^2 \). For the first part of Item 5, note that \( |E(G') \triangle E(G'')| < |Z| n < \alpha n^2 \), which implies that \( |E(G') \triangle E(G')| \leq |E(G') \triangle E(G'')| + |E(G'') \triangle E(G)| < (2\alpha + \gamma)n^2 \). Since \( G'[X \setminus Z] = G''[X \setminus Z] \) and \( G'[Y] = G''[Y] \), it is enough to establish that Items 1, 3 and 4 hold if \( G' \) is replaced by \( G'' \). For Item 1, this is immediate from the definition of \( G'' \); for Items 3 and 4, this follows from our choice of \( Q = \{Q_1, \ldots, Q_q\} \) and \( W_1, \ldots, W_q \) via Lemma 2.4 (with parameter \( \delta = \alpha \)).

\[ \Box \]

4. Proofs of main results

In this section we prove Theorems 1.1 and 1.2. The last ingredient we need is the following key lemma.

**Lemma 4.1.** Let \( \mathcal{F} \) be a (finite or infinite) family of graphs such that

1. \( C_4 \in \mathcal{F} \).
2. For every \( F \in \mathcal{F} \) and for every \( v \in V(F) \), the neighbourhood of \( v \) (in \( F \)) is of size at least 2 and is not a clique.

Suppose \( G \) is a graph with vertex partition \( V(G) = X \cup Y \) such that \( Y \) is an independent set and \( G[X] \) is induced \( \mathcal{F} \)-free. If one must add/delete at least \( \varepsilon |X||Y| \) of the edges between \( X \) and \( Y \) to make \( G \) induced \( \mathcal{F} \)-free, then \( G \) contains at least \( \frac{\varepsilon^4}{2^7}|X|^2|Y|^2 \) induced copies of \( C_4 \).

**Proof.** Let us pick for every \( y \in Y \) a maximal anti-matching \( \mathcal{M}(y) \) in \( G[N_X(y)] \), that is, a maximal collection of pairwise-disjoint non-edges contained in \( N_X(y) \). For every pair of non-edges \( \{u, v\}, \{u', v'\} \in \mathcal{M}(y) \), there must be at least one non-edge between the vertices \( \{u, v\} \) and the vertices \( \{u', v'\} \), as otherwise \( u, v, u', v' \) would span an induced \( C_4 \) in \( X \), in contradiction to the assumptions that \( G[X] \) is induced \( \mathcal{F} \)-free and \( C_4 \in \mathcal{F} \). Therefore, for every \( y \) there are at least \( (|\mathcal{M}(y)| + |\mathcal{M}(y)|) \geq |\mathcal{M}(y)|^2/2 \) non-edges inside the set \( N_X(y) \). For every \( y \in Y \) let \( d_2(y) \) denote the number of unordered pairs of vertices in \( N_X(y) \), that are non-adjacent. Then the above discussion implies that every \( y \in Y \) satisfies

\[ d_2(y) \geq \frac{|\mathcal{M}(y)|^2}{2}. \]
Let $G'$ be the graph obtained from $G$ by deleting, for every $y \in Y$, all edges going between $y$ and the vertices of $\mathcal{M}(y)$. Since $\mathcal{M}(y)$ is spanned by $2|\mathcal{M}(y)|$ vertices, we have

$$|E(G') \triangle E(G)| = 2 \sum_{y \in Y} |\mathcal{M}(y)|. \tag{4}$$

We now claim that $G'$ is induced $\mathcal{F}$-free. Indeed, suppose $U \subseteq V(G)$ spans an induced copy of some $F \in \mathcal{F}$. Since by assumption $G[X]$ is induced $\mathcal{F}$-free and since $G'[X] = G[X]$, there must be some $y \in U \cap Y$. Since the neighbourhood of $y$ in $F$ is of size at least 2 and is not a clique, and since $G'[Y] = G[Y]$ is an empty graph, there must be $u, v \in U \cap X$ for which $u, v \in N_X(y)$ and $\{u, v\} \notin E(G')$. Now, the fact that $u, v$ are connected to $y$ in $G'$ means that neither of them participated in one of the non-edges of $\mathcal{M}(y)$. But then the fact that $\{u, v\} \notin E(G')$ implies that also $\{u, v\} \notin E(G)$ (because we did not change $G[X]$) which in turn implies that $\{u, v\}$ could have been added to $\mathcal{M}(y)$, contradicting its maximality.

By the assumption of the lemma we thus have $|E(G') \triangle E(G)| \geq \varepsilon |X||Y|$. Combining this with (3), (4) and Jensen’s inequality thus gives

$$\sum_{y \in Y} d_2(y) \geq \frac{1}{2} \sum_{y \in Y} |\mathcal{M}(y)|^2 \geq \frac{1}{2} |Y| \cdot \left( \sum_{y \in Y} \frac{|\mathcal{M}(y)|}{|Y|} \right)^2 = \frac{1}{2} |Y| \cdot \left( \frac{|E(G') \triangle E(G)|}{2|Y|} \right)^2 \geq \frac{\varepsilon^2}{8} |X|^2 |Y|.$$

For a pair of distinct vertices $u, v \in X$ set $t(u, v) = 0$ if $\{u, v\} \in E(G)$ and otherwise set $t(u, v)$ to be the number of vertices $y \in Y$ connected to both $u$ and $v$. Recalling that $Y$ is an independent set in $G$, we see that $u, v$ belong to at least $\left( \binom{t(u, v)}{2} \right)$ induced copies of $C_4$. Hence, $G$ contains at least

$$\sum_{u,v \in X} \left( \binom{t(u, v)}{2} \right) \geq \left( \frac{|X|}{2} \right) \cdot \left( \sum_{u,v \in X} \frac{t(u, v)}{\binom{|X|}{2}} \right) = \left( \frac{|X|}{2} \right) \cdot \left( \sum_{y \in Y} \frac{d_2(y)}{\binom{|X|}{2}} \right) \geq \frac{|X|^2}{4} \cdot \frac{\varepsilon^2 |Y|}{4} = \frac{\varepsilon^4}{8} |X|^2 |Y|^2$$

induced copies of $C_4$, where the first inequality is Jensen’s, the following equality is double-counting, and the last inequality uses our above lower bound for $\sum_{y \in Y} d_2(y)$. We are now ready to prove Theorems 1.1 and 1.2.
Proof of Theorem 1.1 Set

\[ \alpha = \frac{\varepsilon^6}{2^{13}}, \quad \gamma = \frac{1}{2}(\alpha/20)^{16000\alpha^{-6}}(\varepsilon/2)^4, \]

and notice that \( \gamma \geq 2^{-(1/\varepsilon)c'} \) for some absolute constant \( c' \). Let \( G \) be an \( n \)-vertex graph which is \( \varepsilon \)-far from being induced \( C_4 \)-free. We apply Lemma 3.7 to \( G \) with the \( \alpha \) and \( \gamma \) defined above. If \( G \) contains \( \Omega(\alpha^c_0\gamma^c_0n^4) \) induced copies of \( C_4 \) (where \( c_0 \) is from Lemma 3.7), then we are done. Otherwise, let \( G', X = X_1 \cup \cdots \cup X_k, Y, Z, Q = \{Q_1, \ldots, Q_\ell\} \) and \( W_i \subseteq Q \) be as in Lemma 3.7. Let \( G'' \) be the graph obtained from \( G' \) by doing the following: for every \( 1 \leq i < j \leq q \), if \( (W_i, W_j) \) is a complete (resp. empty) bipartite graph, then we turn \( (Q_i, Q_j) \) into a complete (resp. empty) bipartite graph. By Item 4 in Lemma 3.7, one of these options holds. By Item 3 in Lemma 3.7, the number of changes made is at most \( \alpha n^2 \). By Item 5 in Lemma 3.7 we have

\[ |E(G'') \triangle E(G)| \leq |E(G'') \triangle E(G')| + |E(G') \triangle E(G)| < (3\alpha + \gamma)n^2 < \frac{\varepsilon}{2}n^2, \]

implying that \( G'' \) is \( \frac{\varepsilon}{2} \)-far from being induced \( C_4 \)-free (as \( G \) is \( \varepsilon \)-far from being induced \( C_4 \)-free). Note that \( |X \setminus Z| \geq \frac{\varepsilon}{2}n \), as otherwise deleting all edges incident to the vertices of \( X \setminus Z \) would make \( G'' \) an empty graph (and hence induced \( C_4 \)-free) by deleting \( |X \setminus Z| \cdot n < \frac{\varepsilon}{2}n^2 \) edges.

Let us assume first that \( G''[X \setminus Z] \) contains an induced copy of \( C_4 \), say on the vertices \( v_1, v_2, v_3, v_4 \). For \( 1 \leq s \leq 4 \), let \( i_s \) be such that \( v_s \in Q_{i_s} \). It is easy to see that by the definition of \( G'' \), every quadruple \( (w_1, \ldots, w_4) \in W_{i_1} \times W_{i_2} \times W_{i_3} \times W_{i_4} \) spans an induced copy of \( C_4 \) in the graph \( G' \). By Item 4 in Lemma 3.7, \( G' \) contains

\[ |W_{i_1}| \cdot |W_{i_2}| \cdot |W_{i_3}| \cdot |W_{i_4}| \geq (\alpha/20)^{16000\alpha^{-6}}|X|^4 \]

\[ \geq (\alpha/20)^{16000\alpha^{-6}}(\varepsilon/2)^4n^4 = 2\gamma n^4 \]

induced copies of \( C_4 \). By Item 5 in Lemma 3.7, \( G[X \setminus Z] \) and \( G'[X \setminus Z] \) differ on less than \( \gamma n^2 \) edges, each of which can participate in at most \( n^2 \) induced copies of \( C_4 \). Thus, \( G \) contains at least \( \gamma n^4 \) induced copies of \( C_4 \), as required.

From now on we assume that \( G''[X \setminus Z] \) is induced \( C_4 \)-free, implying that \( G''[X] \) is induced \( C_4 \)-free (as every \( z \in Z \) is isolated in \( G'' \)). Since \( G'' \) is \( \frac{\varepsilon}{2} \)-far from being induced \( C_4 \)-free, one cannot make \( G'' \) induced \( C_4 \)-free by adding/deleting less than \( \frac{\varepsilon}{2}n^2 \geq \varepsilon|X||Y| \) edges between \( X \) and \( Y \). Hence, we have \( |X||Y| \geq \frac{\varepsilon}{2}n^2 \), as otherwise one could remove all edges between \( X \) and \( Y \), thus making \( G'' \) induced \( C_4 \)-free by removing at most \( \frac{\varepsilon}{2}n^2 \) edges. Notice that the conditions of Lemma 4.1 hold (with respect to the family \( F = \{C_4\} \)) since \( G''[Y] = G'[Y] \) is an independent set (by Item 1 in Lemma 3.7) and
\(G''[X]\) is induced \(C_4\)-free by assumption. By Lemma 4.1, \(G''\) contains at least
\[
\frac{\varepsilon^4}{256}|X|^2|Y|^2 \geq \frac{\varepsilon^6}{512}n^4 = 8n^4 \text{ induced copies of } C_4.
\]
Since \(|E(G'')\triangle E(G)| < (3\alpha + \gamma)n^2 < 4\alpha n^2\), at least \(4\alpha n^4 = \frac{\varepsilon^6}{512}n^4\) of these copies are also present in \(G\). This completes the proof of the theorem.

**Proof of Theorem 1.2**

Set
\[
\alpha = \frac{\varepsilon^6}{213}, \quad \gamma = \frac{1}{2}(\alpha/20)^{105\alpha^{-9}}(\varepsilon/2)^{20\alpha^{-3}},
\]
and notice that \(\gamma \geq 2^{-1(1/\varepsilon)c'}\) for some absolute constant \(c'\). Let \(G\) be an \(n\)-vertex graph which is \(\varepsilon\)-far from being chordal. As in the proof of Theorem 1.1, we apply Lemma 3.7 to \(G\) with the \(\alpha\) and \(\gamma\) defined above. If \(G\) contains \(\Omega(\alpha^{c_0}, \gamma^{c_0}n^4)\) induced copies of \(C_4\), then we are done. Otherwise, let \(G'\),
\[
X=X_1 \cup \cdots \cup X_k, \ Y, \ Z, \ Q=\{Q_1, \ldots, Q_q\} \text{ and } W_i \subseteq Q_i \text{ be as in Lemma 3.7}.
\]

Let \(G''\) be the graph obtained from \(G'\) by doing the following: for every \(1 \leq i < j \leq q\), if \((W_i, W_j)\) is a complete (resp. empty) bipartite graph, then we make \((Q_i, Q_j)\) a complete (resp. empty) bipartite graph. As in the proof of Theorem 1.1, \(G''\) is \(\frac{\varepsilon}{2}\)-far from being chordal, and we have \(|X \setminus Z| \geq \frac{\varepsilon}{2}n\).

Assume first that \(G''[X \setminus Z]\) is not chordal, namely that it contains an induced cycle \(C = v_1 \ldots v_\ell\) of length \(\ell \geq 4\). By Item 1 in Lemma 3.7, \(G''[X_i \setminus Z] = G''[X_i] \setminus Z\) is a clique for every \(1 \leq i \leq k\). Since the cycle \(C\) does not contain a triangle, it can contain at most \(2\) vertices from each of these cliques, implying that \(\ell = |C| \leq 2k \leq 20\varepsilon^{-3} = O(\varepsilon^{-18})\). The bound on \(k\) comes from Lemma 3.7. For \(1 \leq s \leq \ell\), let \(i_s\) be such that \(v_s \in Q_{i_s}\). It is easy to see that by the definition of \(G''\), every \(\ell\)-tuple \((w_1, \ldots, w_\ell) \in W_{i_1} \times \cdots \times W_{i_\ell}\) spans an induced \(\ell\)-cycle in the graph \(G'\). By Item 4 in Lemma 3.7, \(G''\) contains
\[
\prod_{j=1}^{\ell} |W_{i_j}| \geq (\alpha/20)^{4000\alpha^{-6}\ell}|X|^{\ell} \geq (\alpha/20)^{105\alpha^{-9}}(\varepsilon/2)^{20\alpha^{-3}}n^\ell = 2\gamma n^\ell
\]
induced copies of \(C_\ell\). By Item 5 in Lemma 3.7, \(G[X]\) and \(G'[X]\) differ on less than \(\gamma n^2\) edges, each of which can participate in at most \(n^{\ell-2}\) induced copies of \(C_\ell\). Thus, \(G\) contains at least \(\gamma n^\ell\) induced copies of \(C_\ell\), as required.

We now assume that \(G''[X]\) is chordal. Since \(G''\) is \(\frac{\varepsilon}{2}\)-far from being chordal, one must add/delete at least \(\frac{\varepsilon}{2}n^2 \geq \varepsilon|X||Y|\) of the edges between \(X\) and \(Y\) to make \(G''\) chordal. In particular, we have \(|X||Y| \geq \frac{\varepsilon}{2}n^2\).

Note that the family \(\mathcal{F} = \{C_\ell : \ell \geq 4\}\), i.e., the family of forbidden induced subgraphs for chordality, satisfies Conditions 1-2 of Lemma 4.1. Observe that Lemma 4.1 is applicable to \(G''\) (with respect to the family \(\mathcal{F} = \{C_\ell : \ell \geq 4\}\)), as \(G''[Y] = G'[Y]\) is an independent set (by Item 1 in Lemma 3.7), and \(G''[X]\)
is induced \( F \)-free (i.e. chordal) by assumption. By Lemma 4.1, \( G'' \) contains at least \( \frac{\varepsilon^4}{2^4} |X|^2 |Y|^2 \geq \frac{\varepsilon^6}{2^6} n^4 = 8\alpha n^4 \) induced copies of \( C_4 \). Since \( |E(G'') \triangle E(G)| < 4\alpha n^2 \), at least \( 4\alpha n^4 = \frac{\varepsilon^6}{2^4} n^4 \) of these copies are also present in \( G \). So in this case the assertion of the theorem holds with \( \ell = 4 \). This completes the proof. 

5. An impossibility result

In this section we prove Theorem 1.3. It will in fact be more convenient to prove the following equivalent statement.

**Theorem 5.1.** For every function \( g : (0, \frac{1}{2}) \rightarrow \mathbb{N} \) there is a graph family \( \mathcal{F} \) which contains \( C_4 \) and there is a sequence \( \{\varepsilon_k\}_{k=1}^{\infty} \) with \( \varepsilon_k > 0 \) and \( \varepsilon_k \to 0 \), such the following holds. For every \( k \geq 1 \) and \( n \geq n_0(k) \) there is an \( n \)-vertex graph \( G \) which is \( \varepsilon_k \)-far from being induced \( \mathcal{F} \)-free, but still every induced subgraph of \( G \) on \( g(\varepsilon_k) \) vertices is induced \( \mathcal{F} \)-free.

We will need the following theorem due to Erdős [11].

**Theorem 5.2.** For every pair of integers \( k, f \) there is \( n_{5,2} = n_{5,2}(k, f) \) such that every \( k \)-uniform hypegraph with \( n \geq n_{5,2} \) vertices and \( n^{k-f_1-k} \) edges contains a complete \( k \)-partite \( k \)-uniform hypergraph with \( f \) vertices in each part.

For integers \( k, f \geq 1 \), let \( B_{k,f} \) be the graph obtained by replacing each vertex of the cycle \( C_k \) by a clique of size \( f \), and replacing each edge by a complete bipartite graph.

**Lemma 5.3.** For every pair of integers \( k \geq 3 \) and \( f \geq 1 \) there is \( n_{5,3} = n_{5,3}(k, f) \) such that for every \( n \geq n_{5,3} \), the graph \( B_{k,n/k} \) is \( \frac{1}{2k^2} \)-far from being induced \( \{C_4, B_{k,f}\} \)-free.

**Proof.** Let \( V_1, \ldots, V_k \) be the sides of \( G := B_{k,n/k} \) (each a clique of size \( n/k \)). Let \( G' \) be a graph obtained from \( G \) by adding/deleting at most \( \frac{v(G)^2}{2k^2} = \frac{n^2}{2k^2} \) edges. Our goal is to show that \( G' \) is not induced \( \{C_4, B_{k,f}\} \)-free. Let \( H \) be the \( k \)-partite \( k \)-uniform hypergraph with parts \( V_1, \ldots, V_k \) whose edges are all \( k \)-tuples \( (v_1, \ldots, v_k) \in V_1 \times \cdots \times V_k \) such that \( v_1 v_2 \ldots v_k v_1 \) is an induced cycle in \( G' \). Note that in \( G \), every such \( k \)-tuple spans an induced cycle, and that adding/deleting an edge can destroy at most \( \left( \frac{n}{k} \right)^{k-2} \) such cycles. Thus, \( G' \) contains at least \( \left( \frac{n}{k} \right)^k - \frac{n^2}{2k^2} \left( \frac{n}{k} \right)^{k-2} = \frac{1}{2} \left( \frac{n}{k} \right)^k \) of these induced cycles, implying that \( e(H) \geq \frac{1}{2} \left( \frac{n}{k} \right)^k \). For a large enough \( n \) we have \( \frac{1}{2} \left( \frac{n}{k} \right)^k \geq n^{k-f_1-k} \).
and \( n \geq n_{5,2}(k,f) \). Thus, by Theorem 5.2, \( H \) contains a complete \( k \)-partite \( k \)-uniform hypergraph with parts \( U_i \subseteq V_i \), each of size \( f \). This means that in the graph \( G' \), \((U_i,U_j)\) is a complete bipartite graph if \( j-i \equiv \pm 1 \pmod{k} \) and an empty bipartite graph otherwise. If \( G'[U_i] \) is a clique for every \( 1 \leq i \leq k \), then \( U_1 \cup \cdots \cup U_k \) spans an induced copy of \( B_{k,f} \) in \( G' \). Suppose then that \( U_i \) is not a clique for some \( 1 \leq i \leq k \), say \( i = 1 \), and let \( x,y \in U_1 \) be such that \( \{x,y\} \notin E(G') \). Then for every \( z \in U_2 \) and \( w \in U_k \), \( \{x,y,z,w\} \) spans an induced copy of \( C_4 \) in \( G' \). Thus, in any case \( G' \) is not induced \( \{C_4,B_{k,f}\} \)-free.

**Proof of Theorem 5.1** For \( k \geq 5 \) put \( \varepsilon_k = \frac{1}{2k^2} \) and \( f_k = g(\varepsilon_k) \). We will show that the family \( \mathcal{F} = \{C_4\} \cup \{B_{k,f_k} : k \geq 5\} \) satisfies the requirement. Let \( k \geq 5 \), let \( n \geq n_{5,3}(k,f_k) \) and set \( G = B_{k,n/k} \). By Lemma 5.3, \( G \) is \( \varepsilon_k \)-far from being induced \( \{C_4,B_{k,f_k}\} \)-free. Since \( C_4,B_{k,f_k} \in \mathcal{F} \), we get that \( G \) is \( \varepsilon_k \)-far from being induced \( \mathcal{F} \)-free.

We claim that for every \( 4 \leq \ell < k \), \( G \) is induced \( C_{\ell} \)-free. Suppose, for the sake of contradiction, that \( x_1,\ldots,x_\ell,x_1 \) is an induced \( \ell \)-cycle in \( G \). Let \( V_1,\ldots,V_k \) be the sides of \( G = B_{k,n/k} \). If \( |\{x_1,\ldots,x_\ell\} \cap V_i| \leq 1 \) for every \( 1 \leq i \leq k \), then \( x_1,\ldots,x_\ell \) are contained in an induced path, which is impossible. So there is some \( 1 \leq i \leq k \) for which \( |\{x_1,\ldots,x_\ell\} \cap V_i| \geq 2 \). Suppose without loss of generality that \( x_1,x_2 \in V_1 \) (recall that \( V_1,\ldots,V_k \) are cliques). Then \( x_3 \in V_2 \) or \( x_3 \in V_k \), and in either case \( x_1,x_2,x_3 \) span a triangle, a contradiction.

We conclude that the smallest \( F \in \mathcal{F} \) which is an induced subgraph of \( G \), is \( F = B_{k,f_k} \). Thus, every induced subgraph of \( G \) on less than \( v(B_{k,f_k}) = k \cdot g(\varepsilon_k) \) vertices is induced \( \mathcal{F} \)-free, completing the proof.

**Acknowledgement.** We would like to thank the referees for many valuable comments, which significantly improved the presentation of this paper.
