Abstract

In this paper we continue earlier investigations [10, 12, 19] of evolutionary formulations of the Einstein vacuum constraint equations originally introduced by Rácz. Motivated by the strong evidence from these works that the resulting vacuum initial data sets are generically not asymptotically flat we analyse the asymptotics of the solutions of a modified formulation by a combination of analytical and numerical techniques. We conclude that the vacuum initial data sets generated with this new formulation are generically asymptotically flat.

1 Introduction

The Einstein vacuum constraint equations are a subset of the full Einstein field equations (EFE). The triple (Σ, γ_{ab}, K_{ab}) of a 3-dimensional differentiable manifold Σ, Riemannian metric γ_{ab} and a smooth symmetric tensor field K_{ab} on Σ is called a vacuum initial data set if it satisfies the Einstein vacuum constraint equations

\begin{equation}
\begin{aligned}
(3) \, R - K_{ab}K^{ab} + K^2 &= 0, \\
\nabla_a K_a^c - \nabla_c K &= 0,
\end{aligned}
\end{equation}

everywhere on Σ, where \nabla_a is the covariant derivative associated with γ_{ab}, \( (3) R \) is the corresponding Ricci scalar and \( K = K^a_a \) is the mean curvature. For this whole paper we agree that spatial abstract indices \( a, b, \ldots \) are raised and lowered with the metric \( \gamma_{ab} \).

Owing to the work of Choquet-Bruhat and Geroch [16, 23] we know that for every solution of the Einstein vacuum constraints there exists a unique maximal globally hyperbolic
development (a solution of the full vacuum EFE). Constructing solutions of the Einstein vacuum constraints is therefore the first crucial step in exploring solutions to the full vacuum EFE. The Einstein vacuum constraints Eq. (1.1) comprise a set of four nonlinear partial differential equations that constrain the twelve independent components of the two tensor fields $\gamma_{ab}, K_{ab}$. Solving Eq. (1.1) is therefore an under-determined problem, and to the best of our knowledge, there is no clear physically or geometrically preferred way to construct solutions.

One of the most successful methods for solving the constraints is the Lichnerowicz-York conformal approach (see [17] and references therein) which allows one to cast the constraints as a set of non-linear elliptic partial differential equations, which can in principle be solved as a boundary value problem. Solving the equations in this way can be challenging. However, there are several well established methods for doing this that have been very successful both from the analytical and the numerical perspective [4, 5]. Nevertheless, this approach is not without limitation. For example, mathematical problems have been known to arise when solutions with large mean curvatures are sought (see [2, 21] for an overview and references). Other more physical problems, such as spurious radiation [18, 25] also occur. Some researchers have therefore sought other methods of solving the constraints [13, 14, 26, 27].

In this work we focus on one such alternative approach, namely, the evolutionary formulations of the vacuum constraints introduced by Rácz in [30–32, 34]. In his work, Rácz introduced two ways to write the vacuum constraints: as a hyperbolic-algebraic system of PDEs on the one hand, and as a parabolic-hyperbolic system of PDEs on the other hand. In all these cases the constraints are solved as a Cauchy problem similar to earlier work in [3, 14]. First steps in investigating whether this approach has any advantages over more established methods have been carried out in [33] for the constraints of the Maxwell equations and in [22, 28] for the Einstein vacuum constraint equations. The main principal disadvantage of Rácz’s approach (in comparison to solving the vacuum constraints as an elliptic boundary value problem) is that it does not directly allow to control the asymptotics of the resulting vacuum initial data sets at spacelike infinity. This is problematic because certain physical quantities such as the total mass or the centre of mass (see for example [15, 36]), to name a few, are only well defined if the data sets satisfy particular asymptotic conditions. With no control over the asymptotics it is therefore possible that the method generates initial data sets that lack a physical interpretation. Exactly this issue has been explored recently in [10, 12, 19]. It was confirmed that generic solutions of these equations are not \textit{asymptotically flat} (this notion is defined in Section 4 below). This is the case even for small (nonlinear) perturbations of asymptotically flat vacuum initial data sets. Other issues have been observed in [37].

In [12] we proposed an iterative approach to, at least partly, address the asymptotic flatness problem. In this paper here we provide strong evidence (by a combination of analytic and numerical techniques, see below) that a small change of how the free data for Rácz’s parabolic-hyperbolic formulation are specified is sufficient to resolve this issue and to generate vacuum initial data sets which are generically asymptotically flat. In this same
spirit, a completely different modification was suggested in [19]. As in [10, 12], we restrict most of our attention to \( \Sigma \) being the exterior region of an isolated gravitational source and we mostly assume that \( \Sigma \) is foliated by 2-spheres. This will allow us to use the same numerical pseudo-spectral methods developed in [6, 8, 9, 11] based on the \( \bar{\omega} \)- and the spin-weight formalism. As in [10, 12], our focus is on the asymptotics exclusively. In particular, we are not concerned with the properties of the solutions in the strong field regime, e.g. apparent horizons.

The paper is outlined as follows: In Section 2 we briefly summarise the framework of \( 2 + 1 \)-decompositions and introduce Kerr-Schild-like data sets. After a quick summary of Rácz’s original parabolic-hyperbolic formulation of the vacuum Einstein constraints in Section 3.1, we discuss our new modified version of these equations in Section 3.2. Section 4 is then devoted to the discussion of the asymptotics; we define the concept of asymptotic flatness and what it means for the \( 2 + 1 \)-quantities introduced above. Now Section 5.1 yields analytical evidence for our claim that the vacuum initial data sets obtained with our modified parabolic-hyperbolic formulation are better behaved than those with the original formulation in as much as that generic solutions are asymptotically flat. We then support these analytical results with numerics in Section 6.

2 Preliminaries

2.1 The \( 2 + 1 \)-decomposition of initial data sets

We now discuss Rácz’s original parabolic-hyperbolic formulation of the Einstein vacuum constraints. Further details can be found in [30–32, 34]. We use the same conventions as in [12].

Consider an arbitrary 3-dimensional manifold \( \Sigma \), Riemannian metric \( \gamma_{ab} \) and smooth symmetric tensor field \( K_{ab} \); at this stage these are not required to satisfy any equation (such as the vacuum constraints). As before the Levi-Civita covariant derivative associated with \( \gamma_{ab} \) is labelled \( \nabla_a \). We suppose there exists a smooth function \( \rho : \Sigma \rightarrow \mathbb{R} \) whose collection of level sets \( S_\rho \) forms a foliation of \( \Sigma \). This foliation yields a decomposition of \((\Sigma, \gamma_{ab}, K_{ab})\), in full analogy to standard \( 3 + 1 \)-decompositions of spacetimes [1], as follows.

The unit co-normal of any of the 2-surfaces \( S_\rho \) is

\[
N_a = A \nabla_a \rho,
\]

where \( A > 0 \) is the lapse. The induced first and second fundamental forms are therefore, respectively,

\[
h_{ab} = \gamma_{ab} - N_a N_b,
\]

\[
k_{ab} = -\frac{1}{2} \mathcal{L}_N h_{ab}.
\]

We shall label the covariant derivative associated with \( h_{ab} \) as \( D_a \). The tensor field

\[
h^a_b = \delta^a_b - N^a N_b
\]
is the map that projects an arbitrary tensor defined at any point \( p \) in \( \Sigma \) orthogonally to a tensor that is tangent to \( S_p \) at \( p \). If each index of a tensor field defined on \( \Sigma \) contracts to zero with \( N_a \) or \( N^a \) at all \( p \in \Sigma \), then we call that it intrinsic (to the foliation of surfaces \( S_p \)).

Given an arbitrary tensor field on \( \Sigma \) we can create an intrinsic tensor field by contracting each index with \( h^{ab} \). In fact, any tensor can be uniquely decomposed into its intrinsic and its orthogonal parts, e.g.,

\[
K_{ab} = \kappa N_a N_b + N_a p_b + N_b p_a + q_{ab},
\]

with

\[
\kappa = N^a N^b K_{ab}, \quad p_a = h^{c \, a} N^b K_{cb}, \quad q_{ab} = h^{c \, a} h^{d \, b} K_{cd}.
\]

The field \( q_{ab} \) is symmetric and can be further decomposed into its trace and trace-free part (with respect to \( h_{ab} \)) as follows

\[
q_{ab} = Q_{ab} + \frac{1}{2} q h_{ab}, \quad Q_{ab} h^{ab} = 0,
\]

where the relations

\[
q = h^{ab} q_{ab}, \quad Q_{ab} h^{ab} = 0
\]

hold and \( Q_{ab} \) is symmetric.

Now pick an arbitrary vector field \( \rho^a \) such that

\[
\rho^a \nabla_a \rho = 1.
\]

According to Eq. (2.1) there must exist a unique intrinsic vector field \( B^a \), called the shift, such that

\[
\rho^a = A N^a + B^a,
\]

where \( A \) is the lapse in Eq. (2.1). Given \( \rho^a \), we can write Eq. (2.3) as

\[
k_{ab} = - A^{-1} \left( \frac{1}{2} \mathcal{L}_\rho h_{ab} - D_a B_b \right) =: A^{-1} \hat{k}_{ab}.
\]

We also define

\[
\hat{k} := h^{ab} \hat{k}_{ab}.
\]

Finally, the Ricci scalar \((3) R\) associated with \( \gamma_{ab} \) can be written as

\[
(3) R = (2) R - \left( A^{-2} \kappa^2 + A^{-2} k_{ab} \hat{k}_{ab} + 2 A^{-1} D^a D_a A - 2 \left( A^{-1} \mathcal{L}_N \hat{k} - A^{-2} \mathcal{L}_N A \right) \right),
\]

where the Ricci scalar associated with the induced metric \( h_{ab} \) is called \((2) R\). The intrinsic acceleration vector is

\[
v_b = N^a \nabla_a N_b = - A^{-1} D_b A.
\]
2.2 Kerr-Schild-like data sets

In this subsection we introduce data sets (without imposing the constraints yet) of Kerr-Schild form. Such data sets were the basis of our previous work in [10, 12] and we shall continue to use them in particular in Section 6.1. In this paper now we introduce such data sets as follows.

Definition 1. A data set \((\Sigma, \gamma_{ab}, K_{ab})\) is called Kerr-Schild-like if \(\Sigma = \mathbb{R}^3 \setminus B\) where \(B\) is a ball in \(\mathbb{R}^3\) and there exists a smooth function \(V : \Sigma \to \mathbb{R}\) with \(V < 1\), a smooth co-vector field \(l_a\) and a symmetric tensor field \(\dot{\gamma}_{ab}\) such that

\[
\gamma_{ab} = \delta_{ab} - V l_a l_b, \quad K_{ab} = \frac{\sqrt{1-V}}{2} (\nabla_a (V l_b) + \nabla_b (V l_a) - \dot{\gamma}_{ab}),
\]

(2.14)

where \(\delta_{ab}\) is the flat metric on \(\Sigma\), \((\delta^{-1})^{ab}\) its inverse, and \(l_a\) satisfies the condition

\[
(\delta^{-1})^{ab} l_a l_b = 1.
\]

(2.15)

An example of a Kerr-Schild like data set is the standard ingoing Kerr-Schild Schwarzschild slice given by

\[
l_a = \nabla_a r, \quad V = -\frac{2m}{r} \quad \text{and} \quad \dot{\gamma}_{ab} = 0.
\]

Let us now proceed by providing some useful formulas derived from this definition. For

\[
\tilde{l}^a = (\delta^{-1})^{ab} l_b,
\]

(2.16)

it follows

\[
\tilde{l}^a l_a = (\delta^{-1})^{ab} l_a l_b = 1,
\]

(2.17)

\[
\gamma^{ab} = (\delta^{-1})^{ab} + \frac{V}{1-V} \tilde{l}^a \tilde{l}^b,
\]

(2.18)

\[
l^a = \frac{1}{1-V} \tilde{l}^a, \quad l^a l_a = \frac{1}{1-V}.
\]

(2.19)

Suppose now we have chosen a smooth function \(\rho\) on \(\Sigma\) with the properties discussed in Section 2.1 giving rise to a foliation \(S\) in terms of level sets \(S_{\rho}\) diffeomorphic to the 2-sphere. We restrict to the case where \(l_a\) is normal to \(S_{\rho}\), i.e.,

\[
l_a = \pm f \nabla_a \rho,
\]

(2.20)

with

\[
f = \frac{1}{\sqrt{(\delta^{-1})^{ab} \nabla_a \rho \nabla_b \rho}},
\]

(2.21)

as a consequence of Eq. (2.15). From Eqs. (2.1), Eq. (2.20) and Eq. (2.19) we find that

\[
N_a = \sqrt{1-V} l_a,
\]

(2.22)

which means that the lapse defined in Eq. (2.1) is

\[
A = f \sqrt{1-V}.
\]

(2.23)
It now follows from Def. 1 and Eq. (2.2) that

\[ h_{ab} = \delta_{ab} - l_{a}l_{b}. \]  

(2.24)

Since

\[ K_{ab} = \frac{2 - V}{4(1 - V)} (\nabla_{a} V N_{b} + \nabla_{b} V N_{a}) + \frac{V}{2} (\nabla_{a} N_{b} + \nabla_{b} N_{a}) - \frac{\sqrt{1 - V}}{2} \gamma_{ab}, \]  

(2.25)

Eq. (2.5) yields

\[ \kappa = \frac{2 - V}{2(1 - V)^{3/2}} \tilde{p}_{a} \nabla_{a} V - \frac{\sqrt{1 - V}}{2} \gamma_{ab} N_{a}N_{b}, \]  

(2.26)

\[ p_{a} = \frac{2 - V}{4(1 - V)} D_{a} V + \frac{V}{2} v_{a} - \frac{\sqrt{1 - V}}{2} \gamma_{cb} h_{c}^{a} h_{b}^{d}, \]  

(2.27)

\[ q_{ab} = -V k_{ab} - \frac{\sqrt{1 - V}}{2} \gamma_{cd} h_{c}^{a} h_{d}^{b}, \]  

(2.28)

where \( v_{a} \) can be calculated from Eq. (2.13) and \( k_{ab} \) from Eq. (2.10) once a shift vector field \( B_{a} \), and thereby the vector field \( \rho^{a} = A N^{a} + B^{a} \), have been chosen. Notice that we can calculate \( B_{a} \) as

\[ B_{a} = \rho^{b} h_{ab}. \]  

(2.29)

The quantities \( q \) and \( Q_{ab} \) are given by Eq. (2.6) and \( \dot{k}_{ab} \) and \( \dot{k} \) are obtained from Eqs. (2.10) and (2.11).

3 Parabolic-hyperbolic formulations of the vacuum constraints

3.1 Rácz’s parabolic-hyperbolic formulation of the vacuum constraints

Given the function \( \rho \) and the foliation in terms of 2-surfaces \( S_{\rho} \) generated by it as in Section 2.1, the vacuum constraints Eq. (1.1) can now be decomposed into their normal and intrinsic components, and, according to [32] yield the following system of equations:

\[ \dot{k} \mathcal{L}_{\rho} A + A^{2} D^{a} D_{a} A - k B^{a} D_{a} A = \frac{1}{2} A^{3} E + \frac{1}{2} A F, \]  

(3.1)

\[ \mathcal{L}_{\rho} q - B^{a} D_{a} q - AD_{a} p^{a} - 2 p^{a} D_{a} A = k^{ab} Q_{ab} + \frac{1}{2} k^{*} - \dot{k} \kappa, \]  

(3.2)

\[ \mathcal{L}_{\rho} p_{c} - B^{a} D_{a} p_{c} - \frac{1}{2} A D_{c} q - \kappa D_{c} A + Q^{a} D_{a} A + \frac{1}{2} q D_{c} A = p_{a} D_{b} B^{a} - AD_{a} Q^{a} c + \dot{k} p_{c} + AD_{c} \kappa, \]  

(3.3)

where

\[ E = (2) R + 2 \kappa q - 2 p^{a} p_{a} - \dot{Q}_{ab} Q^{ab} + \frac{1}{2} q^{2}, \]  

(3.4)

\[ F = 2(\dot{\rho} k - B^{a} D_{a} k) - \dot{k}_{ab} k^{ab} - k^{2}. \]  

(3.5)
Observe that all quantities here are smooth *intrinsic* tensor fields. It is clear that while this means that all contractions with $N^a$ or $N_a$ vanish, contractions with $\rho^a$ do not, e.g.,

$$p_\rho := p_a \rho^a = p_a B^a$$

as a consequence of Eq. (2.9). However such “components” $p_\rho$ do clearly not constitute a further degree of freedom of the field $p_a$ since $p_\rho = p_a B^a$ is fully determined by its “intrinsic components”. Consistently with this, it is easy to check that the equation for $p_\rho$ obtained by contracting Eq. (3.3) with $\rho^c$ fully decouples from the remaining equations. We remark that instead of thinking of each field in the equations above as intrinsic fields on $\Sigma$, we could equivalently think of them as 1-parameter families of fields on $S^2$ defined by the pull-back along the $\rho$-dependent map $\Phi_\rho : S^2 \to \Sigma, \rho \mapsto (\rho, p)$ to $S^2$. In the following we shall use abstract indices $A, B, \ldots$ for such $\rho$-dependent tensor fields on $S^2$. Indeed, all indices $a, b, \ldots$ in the equations above could be replaced by $A, B, \ldots$, and, at the same type, each Lie-derivative along $\rho^a$ by the derivative with respect to parameter $\rho$. All this is well-known for 3+1-decompositions of spacetimes and is therefore not discussed any further here.

Eqs. (3.1)–(3.3) suggest to group the various fields introduced above are as follows:

**Free data** The fields $B_a, Q_{ab}, h_{ab}$ and $\kappa$ are considered as freely specifiable everywhere on $\Sigma$. All of $\star k, D_a, (2)^R, Q_{ab}$ and $F$ (together with all of the index versions of these) as well as all coefficients in Eqs. (3.1)–(3.3) are fully determined by these on $\Sigma$.

**Unknowns** The quantities $A, q$ and $p_a$ are considered as the unknowns of Eqs. (3.1)–(3.3) once free data have been specified.

According to [30], it can be shown that given arbitrary smooth *Cauchy data*\(^1\) for $A$, $q$ and $p_a$ on an arbitrary $\rho = \rho_0$-leaf of the 2 + 1-decomposition of $\Sigma$, in addition to smooth *free data* everywhere $\Sigma$, the *Cauchy problem* of Eqs. (3.1)–(3.3) in the increasing $\rho$-direction is well-posed, i.e., the equations have a unique smooth solution $A, q$ and $p_a$ at least in a neighbourhood of the initial leaf $S_{\rho_0}$, provided the *parabolicity condition* holds everywhere on $\Sigma$:

$$\star k < 0.$$  \(\text{(3.6)}\)

Clearly if $\star k$ is positive instead, then the Cauchy problem is well-posed in the *decreasing* $\rho$-direction instead. In either case, Eqs. (3.1)–(3.3) is a quasilinear parabolic-hyperbolic system. It is important to notice here that $\star k$ is fully determined by the free data. The condition Eq. (3.6) can therefore be verified *prior* to solving Eqs. (3.1)–(3.3).

### 3.2 Modified parabolic-hyperbolic formulation of the vacuum constraints

The system Eqs. (3.1)–(3.3) has been used in several works among which are [12,19,22,28,35]. The particular choice of how to split the fields into free data and unknowns is however not the only possibility. Motivated by previous studies [12,19], which indicate an instability of these equations in the asymptotically flat setting, we now propose a small modification.

---

\(^1\)The Cauchy datum for $A$ is assumed to be strictly positive everywhere without further notice.
The main result of our paper is that we can provide evidence that this instability observed for Eqs. (3.1)–(3.3) is resolved by this modification.

Recall that $\kappa$ is one of the free data in the formulation introduced in Section 3.1 while $q$ is one of the unknowns. Here now we propose to introduce a new free data field $R$ and then set

$$\kappa = Rq$$

(3.7)

where $q$ continues to be an unknown. The equations resulting from this are obtained from Eqs. (3.1)–(3.3) by replacing all instances of $\kappa$ with $Rq$:

$$k\mathcal{L}_p A + A^2 D^a D_a A - k B^a D_a A = \frac{1}{2} A^3 E + \frac{1}{2} AF,$$

(3.8)

$$\mathcal{L}_p q - B^a D_a q - AD_a p^a - 2p^o D_a A = k^{ab} Q_{ab} + \frac{1}{2} q^k - k R q,$$

(3.9)

$$\mathcal{L}_p p_c - B^a D_a p_c - A \left( \frac{1}{2} + R \right) D_c q = p_a D_b B^a - AD_a Q^{ac} + q^c R D_c A - Q^{ac} D_a A + kp_c + A q D_c R - \frac{1}{2} q D_c A,$$

(3.10)

where, $F$ takes the same form as before and $E$ becomes

$$E = (2) R - 2 p^o p_a - Q_{ab} Q^{ab} + \left( 2 R + \frac{1}{2} \right) q^2.$$

(3.11)

We shall refer to these equations as the **modified parabolic-hyperbolic system** while Eqs. (3.1)–(3.3) shall often be labeled as the **original parabolic-hyperbolic system**.

First we observe that this modification has changed the principal part of the system. It turns out that Eqs. (3.8)–(3.10) is still parabolic-hyperbolic. First, the principal part of Eq. (3.8) is unchanged (and is therefore parabolic provided the same parabolicity condition Eq. (3.6) as before holds), and, second, the subsystem Eqs. (3.9) – (3.10) is symmetrisable hyperbolic with symmetriser

$$\left( \begin{array}{cc} \frac{1}{2} + R & 0 \\ 0 & h^{ce} \end{array} \right)$$

(3.12)

provided

$$\frac{1}{2} + R > 0,$$

(3.13)

where $h^{ce}$ is the intrinsic inverse of $h_{ab}$. We refer to Eq. (3.13) as the **hyperbolicity condition**. This now suggests the following choice:

**Free data:** The fields $B_a$, $Q_{ab}$, $h_{ab}$ and $R$ are free data everywhere on $\Sigma$.

**Unknowns:** The fields $A$, $q$ and $p_a$ are the unknowns.
It follows that for arbitrary free data, for which both the parabolicity condition Eq. (3.6) and the hyperbolicity condition Eq. (3.13) hold, Eqs. (3.8)–(3.10) is a quasilinear parabolic-hyperbolic system and the Cauchy problem in the increasing $\rho$-direction is therefore well-posed (at least locally). Both conditions Eqs. (3.6) and (3.13) are conditions on the free data as before. We remark that our hyperbolicity condition here should not be confused with the hyperbolicity condition found by Rácz in his so-called algebraic-hyperbolic formulation [32].

It is not obvious why Eqs. (3.8)–(3.10) should be “any better” than Eqs. (3.1)–(3.3). The rest of the paper is about exactly this issue.

4 Asymptotics and radial expansions of data sets (without imposing the vacuum constraints yet)

As in [10, 12] we restrict now to the case $\Sigma = \mathbb{R}^3 \setminus B$ where $B$ is an arbitrary fixed ball in $\mathbb{R}^3$ in all of what follows. Moreover, we assume that the level sets of $\rho$ are diffeomorphic to 2-spheres. This implies that we can assume that

$$\Sigma = (\rho_-, \infty) \times S^2$$

for some $\rho_+ > 0$ and we write the points in $\Sigma$ as $(\rho, p)$ with $\rho \in (\rho_-, \infty)$ and $p \in S^2$. Observe carefully that we often use the same symbol $\rho$ for the real parameter $\rho \in (\rho_-, \infty)$ and for the function $\rho$ defined by $(\rho, p) \mapsto \rho$ used for the $2+1$-decomposition. Consider now the manifold $\Sigma = (\rho_-, \infty) \times S^2$ for some $\rho_+ > 0$ as before. An initial data set (not necessarily a solution of the vacuum constraints\footnote{Initial data sets that are solutions of the vacuum constraints are discussed in the sections following this one.}) is equivalently specified by a Riemannian metric $\gamma_{ab}$ and smooth symmetric tensor field $K_{ab}$ on $\Sigma$, or, by the fields $(A, \kappa, q, p_a, B_a, Q_{ab}, h_{ab})$ on $\Sigma$ as in Section 2.1. We shall often speak of $(A, \kappa, q, p_a, B_a, Q_{ab}, h_{ab})$ as the $2+1$-fields associated with $(\gamma_{ab}, K_{ab})$, or, equivalently of $(\gamma_{ab}, K_{ab})$ as the initial data set associated with the $2+1$ quantities $(A, \kappa, q, p_a, B_a, Q_{ab}, h_{ab})$.

Let us now introduce some more notation and further structure. Given any $\rho \in (\rho_-, \infty)$, let $\Phi_\rho : S^2 \to \Sigma$ be the map $p \mapsto (\rho, p)$ introduced earlier. Recalling the index conventions before, we let $(\Omega^{-1})^{AB}$ be the contravariant round unit metric on $S^2$. Sometimes it is useful to use standard polar coordinates $(\theta, \varphi)$ on $S^2$ in terms of which the components of $(\Omega^{-1})^{AB}$ take the form of the matrix diag$(1, \sin^{-2} \theta)$. Given now an arbitrary smooth intrinsic tensor field $T_{a\ldots b}$ on $\Sigma$, let $T_{A\ldots B}$ be the ($\rho$-dependent) pull-back to $S^2$ as discussed before. We then define the $\rho$-dependent norm

$$|T_{a\ldots b}|^2 := T_{A'\ldots B'} T_{A\ldots B} (\Omega^{-1})^{AA'} \cdots (\Omega^{-1})^{BB'}.$$

(4.1)

Notice that this is a norm only for intrinsic tensor fields on $\Sigma$. Given this we write $T_{a\ldots b} = O \left( \frac{1}{\rho} \right)$ provided there is a uniform constant $C$ such that $|T_{a\ldots b}| \leq C \rho^{-k}$ sufficiently close...
to \( \rho = \infty \). We say that \( T_{a...b} \) has an \textit{asymptotic radial expansion of order} \( k \) (near \( \rho = \infty \)) provided

\[
T_{a...b} = \sum_{i=0}^{k-1} T^{(i)}_{a...b} \rho^{-i} + O \left( \frac{1}{\rho^k} \right),
\]

(4.2)

where the coefficients \( T^{(i)}_{a...b} \) are smooth intrinsic tensor fields on \( \Sigma \) which do not depend on \( \rho \), i.e., \( \mathcal{L}_\rho T^{(i)}_{a...b} = 0 \). If \( T_{a...b} = O(1) \) then we say \( T_{a...b} \) as an \textit{asymptotic radial expansion of order} \( 0 \). In order to simplify the notation, we sometimes shall use these notions of the norm and the \( O \)-symbol for \textit{general} tensor fields on \( \Sigma \) even when they are not intrinsic. In this case observe that this norm and this \( O \)-symbol are “completely blind” to all “transversal components” of the tensor field.

For the following it is also useful to define \( \Omega_{ab} \) as the tensor field on \( \Sigma \) with the property \( \rho^a \Omega_{ab} = 0 \) whose pull-back along the map \( \Phi_\rho \) above equals the covariant round unit metric on the 2-sphere for each \( \rho \), i.e., the inverse of \((\Omega^{-1})^{AB} \). Notice carefully that \( \Omega_{ab} \) defined this way is \textit{not} intrinsic to the foliation (unless the shift vector field \( B^a \) vanishes). Its components with respect to adapted coordinates \((\rho, \vartheta, \varphi)\) on \( \Sigma \) as introduced before correspond to the matrix \( \text{diag}(0,1, \sin^2 \vartheta) \).

In all of what follows we shall assume without further notice that \( \rho_- \) is sufficiently large so that all \( 2+1 \)-quantities are well-defined. Recall that asymptotically flat data sets have been studied by us before in \cite{10,12} where we have we used the same definitions originally from \cite{20}.

\textbf{Definition 2.} The triple \((\Sigma, \gamma_{ab}, K_{ab})\) with \( \Sigma = \mathbb{R}^3 \setminus \overline{B} \) where \( B \) is a ball in \( \mathbb{R}^3 \) is called an \textit{asymptotically flat initial data set} provided there exist coordinates \( \{x^i\} \) on \( \Sigma \) such that the components of \( \gamma_{ab} \) and \( K_{ab} \) with respect to these coordinates satisfy, respectively,

\[
\gamma_{ij} = \left( 1 + \frac{2M}{R} \right) \delta_{ij} + O \left( \frac{1}{R^2} \right), \quad K_{ij} = O \left( \frac{1}{R^2} \right),
\]

(4.3)

in the limit

\[
R = \left( \sum_{a=1}^{3} (x^i)^2 \right)^{1/2} \to \infty,
\]

(4.4)

where \( \delta_{ij} = \text{diag}(1,1,1) \). The quantity \( M \in \mathbb{R} \) is called the ADM mass.

Asymptotic flatness therefore implies conditions on the asymptotics of \( 2+1 \) quantities associated with an initial data sets \((\Sigma, \gamma_{ab}, K_{ab})\); see also \cite{10,12,19}.

\textbf{Result 1 (Asymptotically flat data sets).} An data set \((\Sigma, \gamma_{ab}, K_{ab})\) is asymptotically flat with ADM mass \( A^{(1)} \) provided all corresponding \( 2+1 \)-fields have the following asymptotic radial expansions:

1. The expansion of \( A \) is of order 2 with \( A^{(0)} = 1 \) and \( A^{(1)} = \text{const} \).
2. The expansion of $B_a$ is of order 1 with $B_a^{(0)} = 0$.

3. The expansion of $h_{ab}$ is of the form $\rho^{-2} h_{ab} = \Omega_{ab} + O(\rho^{-2})$.

4. The expansion of $q$ is of order 2 with $q^{(0)} = q^{(1)} = 0$.

5. The expansion of $p_a$ is of order 1 with $p_a^{(0)} = 0$.

6. The expansion of $Q_{ab}$ is $Q_{ab} = O(1)$.

7. The expansion of $\kappa$ is of order 2 with $\kappa^{(0)} = \kappa^{(1)} = 0$.

Proof. As before we assume that $\Sigma = (\rho, \infty) \times S^2$ with radial parameter $\rho$. For the following it is useful to introduce coordinates $(\rho, \vartheta, \varphi)$ on $\Sigma$ where $(\vartheta, \varphi)$ are standard polar coordinates on each leaf diffeomorphic to $S^2$. As mentioned before the components of $\Omega_{ab}$ with respect to these coordinates take the form \( \text{diag}(0, 1, \sin 2\vartheta) \). Under the assumptions above, the components of $\gamma_{ab}$ with respect to these coordinates are

\[
\gamma_{\alpha\beta} = \text{diag} \left( 1 + \frac{2A^{(1)}}{\rho}, \rho^2, \rho^2 \sin^2 \vartheta \right) + \begin{pmatrix}
O \left( \frac{1}{\rho} \right) & O \left( \frac{1}{\rho} \right) & O \left( \frac{1}{\rho} \right) \\
O \left( \frac{1}{\rho} \right) & O(1) & O(1) \\
O \left( \frac{1}{\rho} \right) & O(1) & O(1)
\end{pmatrix},
\]

where the $O$-symbol for each component here is interpreted as that for scalar functions on $\mathbb{R}^3$. With respect to the new radial coordinate $R = \rho - A^{(1)}$, the components of $\gamma_{ab}$ are therefore

\[
\gamma_{\alpha'\beta'} = \omega^2 \text{diag} \left( 1, R^2, R^2 \sin^2 \vartheta \right) + \begin{pmatrix}
O \left( \frac{1}{R} \right) & O \left( \frac{1}{R} \right) & O \left( \frac{1}{R} \right) \\
O \left( \frac{1}{R} \right) & O(1) & O(1) \\
O \left( \frac{1}{R} \right) & O(1) & O(1)
\end{pmatrix},
\]

where $\omega^2 = 1 + \frac{2A^{(1)}}{R}$. Transforming the polar coordinates $(R, \vartheta, \varphi)$ to Cartesian coordinates in the standard way, we finally obtain

\[
\gamma_{ij} = \omega^2 \text{diag} \left( 1, 1, 1 \right) + \begin{pmatrix}
O \left( \frac{1}{R} \right) & O \left( \frac{1}{R} \right) & O \left( \frac{1}{R} \right) \\
O \left( \frac{1}{R} \right) & O \left( \frac{1}{R} \right) & O \left( \frac{1}{R} \right) \\
O \left( \frac{1}{R} \right) & O \left( \frac{1}{R} \right) & O \left( \frac{1}{R} \right)
\end{pmatrix},
\]

as required for asymptotic flatness. We can therefore identify $A^{(1)}$ with the quantity $M$. The same arguments applied to $K_{ab}$ yield that the condition for asymptotic flatness is satisfied provided $\kappa^{(0)} = \kappa^{(1)} = 0$, $p_a^{(0)} = 0$ and $q_{ab} = O(1)$ (which is equivalent to assumptions 4 and 6). \( \Box \)
Given an arbitrary initial data set (not necessarily solving the constraints), then we can show that \( \dot{k} = -2/\rho + O(1) \), and therefore \( \dot{k} < 0 \) for sufficiently large \( \rho \); cf. Eq. (3.6). Since general asymptotically flat data sets of the form in Result 1 imply that \( \mathcal{R} = O(1) \), they can only be used as backgrounds for solving the modified system Eqs. (3.8)–(3.10), if we impose additional conditions to ensure Eq. (3.13). We discuss this issue below.

Here now we return briefly to Kerr-Schild-like data sets introduced in Section 2.2. To this end we introduce an arbitrary smooth function \( r \) on \( \Sigma \) with the property that
\[
r = \rho + O(\rho^{-1});
\]
notice carefully that we demand that no \( O(1) \)-term is present in this expansion. In terms of this function \( r \), we assume that the flat metric \( \delta_{ab} \) in Def. 1 takes the form
\[
\delta_{ab} = \nabla_a r \nabla_b r + r^2 \Omega_{ab} \quad (4.6)
\]
where \( \Omega_{ab} \) was introduced above. Given this it is straightforward to show that the function \( f \) in Eqs. (2.20) and (2.21) is \( f = 1 + O(\rho^{-2}) \), that \( \rho^{-2} h_{ab} = \Omega_{ab} + O(\rho^{-2}) \) as a consequence of Eq. (2.24) and that \( B_a = O(\rho^{-1}) \) from Eq. (2.29). It follows from Result 1 and the formulas in Section 2.2 that the Kerr-Schild-like data set is asymptotically flat provided \( V \) has an asymptotic radial expansion of order 2 where \( V^{(0)} = 0 \) and \( V^{(1)} = \text{const} \). In this case the ADM mass is \( M = -V^{(1)}/2 \).

5 Vacuum initial data sets obtained by the modified parabolic-hyperbolic system

5.1 The spherically symmetric case
In this section we analyse the asymptotics of vacuum initial sets obtained as solutions of Eqs. (3.8)–(3.10). Recall that Eqs. (3.1)–(3.3) have been analysed in [12, 19]. We present evidence that all the instabilities regarding asymptotic flatness, which were found for the original system, are resolved by this modification.

The general idea here and in the following is to pick a background initial data set (in general not a solution of the constraints) which is asymptotically flat according to Result 1 in a first step. From this background data set, we then read off the free data for solving Eqs. (3.8)–(3.10) in a second step. We start this subsection with the simpler spherically symmetric case in which Eqs. (3.8)–(3.10) reduces to a system of ordinary differential equations. To this end we consider a backgrounds in Kerr-Schild-like form as in Section 2.2 with Eqs. (4.5) – (4.6). We impose spherical symmetry by requiring that \( V \) only depends on \( \rho \) and that \( r = \rho \). We also choose \( \gamma_{ab} = 0 \). The 2 + 1-quantities defined by this are
\[
Q_{ab} = 0, \quad h_{ab} = \rho^2 \Omega_{ab}, \quad B_a = 0, \quad \mathcal{R} = \frac{(2 - V)\rho \partial_\rho V}{4(1 - V) V}, \quad (5.1)
\]
\footnote{Without going into technical details we assume here that the \( O \)-symbol does not only control the fields themselves as discussed before, but also sufficiently many of their derivatives in the natural way.}
and

\[ q = \frac{2V}{\rho \sqrt{1-V}}, \quad p_a = 0, \quad A = \sqrt{1-V}. \tag{5.2} \]

In order to ensure that \( \mathcal{R} \) is a smooth quantity, we assume that \( \partial_\rho V/V \) is well-defined and finite for all \( \rho > 0 \).

We use Eq. (5.1) now as a background to determine the free data for the modified parabolic-hyperbolic system Eqs. (3.8)–(3.10). Since \( q, p_a \) and \( A \) are supposed to be found as solutions of the equations we therefore ignore Eq. (5.2). In order to appeal to spherically symmetry, we look for solutions under the restriction \( p_a = 0 \) and where the unknowns \( A \) and \( q \) only depend on \( \rho \). With this, Eqs. (3.8)–(3.10) take the form

\[ \partial_\rho q = -\frac{2}{\rho} \left( \frac{1}{2} - \mathcal{R} \right) q, \tag{5.3} \]
\[ \partial_\rho A = -\frac{\rho}{4} \left( \frac{2}{\rho^2} + \left( 2\mathcal{R} + \frac{1}{2} \right) q^2 \right) A^3 + \frac{1}{2\rho} A. \tag{5.4} \]

It is surprising\(^4\) that for any function \( V \) which satisfies the previous restrictions, we can write down the general solution explicitly as

\[ q = \frac{2C V}{\rho \sqrt{1-V}}, \tag{5.5} \]
\[ A = \sqrt{\frac{(1-V)\rho}{\rho - 2m - (\rho - 2m)V + \rho C^2 V^2}}, \tag{5.6} \]

where \( m, C \in \mathbb{R} \) are free constants. It is interesting to notice that this only agrees with Eq. (5.2) if \( C = 1 \) and \( V = -2m/\rho \). Irrespective of the choice of \( V \), the Hawking mass \(^{[24]}\) of each surface \( S_\rho \) of the resulting vacuum initial data set turns out to be

\[ m_H = m, \tag{5.7} \]

and is therefore independent of \( \rho \).

Since we study vacuum solutions in somewhat more detail in the next subsection, let us now consider the following specific choice of the function \( V \)

\[ V = \frac{-V}{\rho}, \tag{5.8} \]

for an arbitrary constant \( V \in \mathbb{R} \). From the discussion at the end of Section 4, the background data set above is therefore asymptotically flat with mass \( V/2 \). With this choice the solutions Eq. (5.5)–(5.6) have the following asymptotic expansions

\[ A = 1 + \frac{m}{\rho} + O \left( \frac{1}{\rho^2} \right), \quad q = -\frac{2C V}{\rho^2} + O \left( \frac{1}{\rho^3} \right), \quad \kappa = \mathcal{R} q = \frac{CV}{\rho^2} + O \left( \frac{1}{\rho^3} \right). \tag{5.9} \]

\(^4\)This is not possible for the original system; see [12].
It is a consequence of Result 1 that the resulting vacuum initial data set is therefore asymptotically flat with ADM mass $m \in \mathbb{R}$ irrespective of the choice of $V > 0$ and $C \in \mathbb{R}$. In contrast to our findings in [12] for the original system, this demonstrates that the modified parabolic-hyperbolic system "performs significantly better" and in a far more stable manner in the asymptotically flat setting. It is interesting that the background mass $V/2$ and the ADM mass $m$ of the resulting vacuum data set are generally distinct.

5.2 Asymptotic radial expansions of vacuum initial data sets (without symmetries)

In this section we use asymptotic expansions to study the asymptotics of vacuum initial data sets obtained by the modified system Eqs. (3.8)–(3.10) for a large class of backgrounds without imposing symmetries. Assuming certain asymptotic radial expansions are valid and the free data satisfy appropriate assumptions, we demonstrate that the solutions of the constraints are always asymptotically flat in consistency with our findings in the spherically symmetric case in Section 5.2. In the section following this one, we then support the strong assumptions which we are required to make here by numerical computations. We focus on the modified system Eqs. (3.8)–(3.10). We refer to [12] for a corresponding result for the original system Eqs. (3.1)–(3.3) which demonstrates that general solutions of the original system are not asymptotically flat.

**Result 2.** Let $\Sigma = (\rho_-, \infty) \times S^2$ for some $\rho_- > 0$. Consider arbitrary smooth free data fields $R, B_a, Q_{ab}$ and $h_{ab}$ on $\Sigma$ with the properties:

1. The scalar function $R$ has an asymptotic radial expansion of order 2 such that $R^{(0)} = -1/2$ and $R^{(1)}$ is a strictly positive function.

2. The intrinsic covector field $B_a$ has an asymptotic radial expansion of order 1 with $B_a^{(0)} = 0$.

3. The symmetric tracefree intrinsic tensor field $Q_{ab}$ has an asymptotic radial expansion of order 2 with $Q_{ab}^{(0)} = Q_{ab}^{(1)} = 0$.

4. The symmetric intrinsic tensor field $h_{ab}$ has a asymptotic radial expansion of the form $\rho^{-2}h_{ab} = \Omega_{ab} + O(\rho^{-2})$.

Then the parabolicity and the hyperbolicity conditions, see Eqs. (3.6) and (3.13), hold for sufficiently large $\rho$, and, for any solution $A, q, p_a$ of the modified parabolic-hyperbolic system Eqs. (3.8)–(3.10) with the properties

1. $A$ is strictly positive and has an asymptotic radial expansion of order 2,

2. $q$ has an asymptotic radial expansion of order 2,

3. $p_a$ is an intrinsic co-vector field with an asymptotic radial expansion of order 2,
we find
\[ q^{(0)} = q^{(1)} = 0, \quad p_{a}^{(0)} = p_{b}^{(1)} = 0, \quad A^{(0)} = 1, \quad A^{(1)} = \text{const.} \]

The vacuum initial data set corresponding to the \(2 + 1\)-quantities \((A, q, p_{a}, \mathcal{R}, B_{a}, Q_{ab}, h_{ab})\) is therefore asymptotically flat with ADM mass \(A^{(1)}\).

The conditions for the free data fields are compatible with Result 1. Observe, however, that the restriction for \(Q_{ab}\) and \(\mathcal{R}\) are in fact stronger than the ones required by Result 1. The additional condition on \(\mathcal{R}\) ensures that Eq. (3.13) holds in addition to Eq. (3.6). It is a non-trivial outcome of the analysis that Result 2 would in general not hold if \(\mathcal{R}^{(0)} \neq -1/2\).

**Proof of Result 2.** We have discussed before
\[ \dot{k} = -\frac{2}{\rho} + O\left(\frac{1}{\rho^2}\right), \tag{5.10} \]
as a consequence of the hypothesis and that therefore Eq. (3.6) holds for sufficiently large \(\rho\). We also find that
\[ \mathcal{R} + \frac{1}{2} = \frac{\mathcal{R}^{(1)}}{\rho} + O\left(\frac{1}{\rho^2}\right) \tag{5.11} \]
and that the assumption \(\mathcal{R}^{(1)} > 0\) therefore implies Eq. (3.13) for sufficiently large \(\rho\) as well. Eqs. (3.8)–(3.10) is therefore parabolic-hyperbolic asymptotically. Now we attempt to solve Eqs. (3.8)–(3.10) order by order in \(\rho\). The two leading orders of Eq. (3.9) immediately imply \(q^{(0)} = q^{(1)} = 0\). Given this, the leading order of Eq. (3.8) yields the equation
\[ \hat{\Delta}A^{(0)} = -\frac{1 - \left(A^{(0)}\right)^2}{A^{(0)}} = F[A^{(0)}], \tag{5.12} \]
where \(\hat{\Delta}\) is the Laplace operator associated with the round 2-sphere metric \(\Omega_{AB}\). It is clear that \(A^{(0)} = 0\) cannot be a solution and we rule out all negative solutions by assumption. One positive solution is \(A^{(0)} = 1\), in fact, this is the only smooth strictly positive solution: Suppose there were two different smooth strictly positive solutions \(A^{(0)}\) and \(\tilde{A}^{(0)}\) of Eq. (5.12). Then a standard integration by parts argument implies
\[ -\|\tilde{D}(A^{(0)} - \tilde{A}^{(0)})\|^2 = \langle A^{(0)} - \tilde{A}^{(0)}, F[A^{(0)}] - F[\tilde{A}^{(0)}] \rangle, \tag{5.13} \]
where the norm and the scalar product here are the standard \(L^2\)-norm and \(L^2\)-scalar product on the 2-sphere with respect to \(\Omega_{ab}\). One can easily check that
\[ F[A^{(0)}] - F[\tilde{A}^{(0)}] = \frac{A^{(0)} - \tilde{A}^{(0)}}{A^{(0)} + 1} \left(A^{(0)} - \tilde{A}^{(0)}\right). \tag{5.14} \]
Since the fraction on the right-hand side is strictly positive if \(A^{(0)}\) and \(\tilde{A}^{(0)}\) are strictly positive, the right-hand side of Eq. (5.13) is therefore non-negative. Since the left-hand side
however is non-positive, the implies that $A^{(0)}$ and $\tilde{A}^{(0)}$ can differ at most by a constant. However, one can easily check that $A^{(0)} = 1$ is the only positive constant solution. Given this, the two leading-orders of Eq. (3.10) imply that $p_a^{(0)} = p_a^{(1)} = 0$. Finally, we look at the third order ($\rho^{-3}$)-term of Eq. (3.10) to get
\[ \Delta A^{(1)} = 0, \] (5.15)
from which we conclude that $A^{(1)}$ is an arbitrary constant. Result 1 now implies that these solutions are asymptotically flat and that $A^{(1)}$ is the ADM mass. 

6 Numerical investigations

6.1 Black hole background data sets

Our analytical results in Section 5 suggest that general solutions of the modified parabolic-hyperbolic system Eqs. (3.8)–(3.10) are asymptotically flat provided the free data satisfy certain asymptotic conditions, in contrast to solutions of the original system Eqs. (3.8)–(3.10); see [12]. In this section now we support these results by numerical calculations.

In [12] we introduced a framework to construct, in principle, multiple black hole background data sets which then provide the free data to solve the constraint equations in a next step. Here we give a short summary of our procedure which is based on the formalism presented in Section 2.2. Inspired by the ideas presented in [14] we imagine to have $N$ black hole-like bodies at coordinate positions $(x_i, y_i, z_i)$ with masses $M_i$ for $i = 1, \ldots, N$. Using $(x, y, z)$ to label Cartesian coordinates on $\Sigma$ and setting
\[ u(x, y, z) = \sum_{i=0}^{N} \frac{M_i}{r_i(x, y, z)}, \] (6.1)
where
\[ r_i(x, y, z) = \sqrt{(x - x_i)^2 + (y - y_i)^2 + (z - z_i)^2}, \] (6.2)
we define the function $\rho$ as
\[ \rho(x, y, z) = \sum_{i=0}^{N} \frac{M_i}{u(x, y, z)}. \] (6.3)

Here we restrict to the binary case $N = 2$ and write $M_1 = M_+, M_2 = M_-$, $r_1 = r_+$ and $r_2 = r_- \text{ where}$
\[ r_{\pm} = (0, 0, \pm Z_{\pm}), \] (6.4)
for constants $Z_{\pm} \geq 0$. In contrast to [12] we now impose a “centre of mass condition” (the reason for this is given below)
\[ Z_+ M_+ - Z_- M_- = 0, \] (6.5)
and therefore choose

\[ Z_- = Z, \quad Z_+ = \frac{M_-}{M_+} Z, \quad (6.6) \]

for some \( Z \geq 0 \). Notice that \( M_- = 0 \) together with \( Z = 0 \) yields the case of a single black hole. Fig. 1 shows examples of contour plots of the function \( \rho \). It is clear from Fig. 1 that there is a critical value of \( \rho \) where the surfaces undergo a topology change. For \( \rho < \rho_{\text{crit}} \), each contour is the union of two disconnected 2-spheres where

\[ \rho_{\text{crit}} = Z \frac{(M_+ + M_-)^2}{M_+ (\sqrt{M_+ + \sqrt{M_-}})^2}. \quad (6.7) \]

However, each \( \rho = \text{const-surface} \) is diffeomorphic to a single 2-sphere if \( \rho > \rho_{\text{crit}} \). Eq. (6.7) holds under the assumption that \( M_+ > 0 \) and \( M_- Z \geq 0 \). In all of what follows we restrict to this latter exterior regime of \( \mathbb{R}^3 \) where the collection of \( \rho = \text{const-surfaces} \) give rise to a foliation. Finally, given all this, we pick

\[ V = -2u, \quad \dot{\gamma}_{ab} = 0, \quad (6.8) \]

and

\[ r = \sqrt{x^2 + y^2 + z^2}, \quad (6.9) \]

as in [12] and then obtain an initial data set (not necessarily a solution of the constraints) in the Kerr-Schild form using Section 2.2 together with Eq. (4.6). We find that the resulting data set agrees with the Schwarzschild Kerr-Schild data set with mass \( M_+ \) in the single black hole case \( M_- = Z = 0 \). Moreover, we see easily that Eq. (4.5) holds as a consequence of the centre of mass condition Eq. (6.5).

We can now show by direct calculations that for any \( M_+, M_- \) and \( Z \) as above, the hypothesis of Result 2 for \( R, B_a, Q_{ab} \) and \( h_{ab} \) are satisfied at least for all sufficiently large \( \rho \). The hypothesis about the unknown fields \( A, q \) and \( p_a \) can, however, as a matter of principle, not be verified a-priori. The main purpose of the following numerical experiments is to provide evidence that the conclusions of Result 2, namely that the resulting vacuum initial data sets are always asymptotically flat, hold nevertheless.

### 6.2 Numerical setup

Given a background data set in Section 6.1, the next task is to numerically solve the Cauchy problem of Eqs. (3.8)–(3.10) with free data determined by this background. We explain below that we use two different ways to specify Cauchy data in the two following numerical examples. As discussed in more detail in [12], while the background data sets are given in Cartesian coordinates \((x, y, z)\) on \( \Sigma \), or, equivalently in corresponding spherical coordinates \((r, \theta, \phi)\) using Eq. (6.9), the evolutions of Eqs. (3.8)–(3.10) must be performed in adapted 2+1-coordinates \((\rho, \vartheta, \varphi)\) where \( \rho \) is given by Eqs. (6.1) – (6.3) and where \((\vartheta, \varphi)\) are intrinsic polar coordinates on each \( \rho = \text{const-surface} \) diffeomorphic to \( S^2 \). As in [12] we choose

\[ \vartheta = \theta, \quad \varphi = \phi. \]
Figure 1: Contour plots of the function $\rho(x, y, z)$ defined by Eqs. (6.1) – (6.3) for $M_+ = M_- > 0$ and $Z > 0$. The left plot shows $\rho$ close to the two black hole positions, while the right figure shows contours for large distances. Both plots restrict to the $x$-$z$-plane. It is evident that the contours become round 2-spheres in the limit of large distances.

This completely fixes the coordinate transformation between the two coordinate systems $(r, \theta, \phi)$ and $(\rho, \vartheta, \varphi)$ on $\Sigma$.

Since the exterior region is foliated by 2-spheres, we can apply the spin-weight formalism following [7–11, 29]. A brief summary is given in Section A in the appendix. We express the covariant derivative operator $D_a$ (defined with respect to the intrinsic metric $h_{ab}$) in terms of the covariant operator $\hat{D}_a$ defined with respect to the round unit-sphere metric $\Omega_{ab}$; recall that $D_a - \hat{D}_a$ can be expressed by some smooth intrinsic tensor field. Using Section A, we can then express the covariant derivative operator $\hat{D}_a$ in terms of the $\bar{\partial}$- and $\bar{\partial}'$-operators [29]. Once all of this has been completed for all terms in Eqs. (3.8)–(3.10), each of these equation and each term ends up with a consistent well-defined spin-weight.

Most importantly, however, all terms are explicitly regular: Standard polar coordinate issues at the poles of the 2-sphere disappear when all quantities are expanded in terms of spin-weighted spherical harmonics and Eqs. (A.5) and (A.6) are used to calculate the intrinsic derivatives. From the numerical point of view this gives rise to a (pseudo)-spectral scheme. We can therefore largely reuse the code presented in [12] subject to two minor changes: (1) the definition of $\rho$ now allows that $Z_+ \neq Z_-$ in agreement with Eq. (6.6), and, (2) all instances of $\kappa$ in the equations are now replaced with $Rq$ in agreement with our modification which leads to Eqs. (3.8)–(3.10). These two changes do not significantly affect our numerical methods. Once the appropriate changes were made to the code, convergence tests (analogous to the ones presented in [12]) were carried out and the appropriate behaviour was observed. All of the following simulations were carried out using the adaptive SciPy ODE solver odeint$^5$.

Notice that the background data sets constructed in Section 6.1 are axially symmetric

$^5$See https://docs.scipy.org/doc/scipy/reference/generated/scipy.integrate.odeint.html.
and hence there is no dependence on the angular coordinate $\varphi = \phi$. Motivated by this we restrict to numerical solutions of Eqs. (3.8)–(3.10) with that same symmetry in all of what follows. We can therefore restrict to the axisymmetric case of the spin-weight formalism in Section A.

6.3 Axisymmetric perturbations of single Schwarzschild black hole initial data

In this section now we use the background data set given in Section 6.1 for $M_+ = 1$ and $M_- = Z = 0$ (the “single black hole case”). The free data for Eqs. (3.8)–(3.10) are therefore given by Eq. (5.1) with $V = \frac{-1}{\rho}$. It follows from Section 5 that

$$q|_{\rho = \rho_0} = \hat{q}|_{\rho = \rho_0} + \varepsilon \sin (\theta), \quad A|_{\rho = \rho_0} = \hat{A}|_{\rho = \rho_0} + \varepsilon \sin (\theta), \quad p_a|_{\rho = \rho_0} = 0,$$

(6.11)

for some freely specifiable constant $\varepsilon \in \mathbb{R}$. For small values of $\varepsilon$, we can interpret the resulting vacuum initial data sets as perturbations of single Schwarzschild black hole initial data.

Given these background data and Cauchy data, we then numerically solve Eqs. (3.8)–(3.10). Using the formalism in Section A these equations take the form

$$\partial_\rho A = -\frac{\rho}{4} \left( \frac{2}{\rho^2} (1 - 2p\bar{p}) + \left( 2\mathcal{R} + \frac{1}{2} \right) q^2 \right) A^3 + \frac{1}{2\rho} \left( 1 + A \bar{\delta} (\bar{\delta} (A)) \right) A,$$

(6.12)

$$\partial_\rho q = \frac{1}{\sqrt{2} \rho^2} (\bar{\delta} (p) + \bar{\delta} (\bar{p})) A - \frac{2}{\rho} \left( \frac{1}{2} - \mathcal{R} \right) q + \frac{2}{\rho^2 \sqrt{2}} \left( p \bar{\delta} (A) + \bar{p} \bar{\delta} (A) \right),$$

(6.13)

$$\partial_\rho p = A \left( \frac{1}{2} + \mathcal{R} \right) \bar{\delta} (q) - \frac{2}{\rho} \bar{p} + \frac{1}{\sqrt{2}} \left( \mathcal{R} - \frac{1}{2} \right) q \bar{\delta} (A),$$

(6.14)

$$\partial_\rho \bar{p} = A \left( \frac{1}{2} + \mathcal{R} \right) \bar{\delta} (q) - \frac{2}{\rho} p + \frac{1}{\sqrt{2}} \left( \mathcal{R} - \frac{1}{2} \right) q \bar{\delta} (A),$$

(6.15)

where

$$p = \frac{1}{\sqrt{2}} p_a \left( \partial_\theta^0 - i \csc \theta \partial_\varphi^0 \right), \quad \bar{p} = \frac{1}{\sqrt{2}} p_a \left( \partial_\theta^0 + i \csc \theta \partial_\varphi^0 \right),$$

(6.16)

and, see Eq. (5.1),

$$\mathcal{R} = -\frac{1}{2} + \frac{1}{4(1 + \rho)}.$$
The quantities $A$ and $q$ have spin-weight zero, while $p$ and $\bar{p}$ have spin-weight 1 and $-1$, respectively. For this particular symmetry (and the particular representation of the underlying bundle) we can assume that

$$p = \bar{p}.$$  

In order to present our numerical calculations now and use them to check the predictions from Result 2 we consider the sup-norm over $S^2$ defined, for any smooth scalar function $F(\rho, \vartheta)$ (such as $A$ and $q$ above), as

$$\|F\|_{(\rho)} = \max_{\vartheta \in [0, \pi]} |F(\rho, \vartheta)|.$$  

(6.17)

For $p_a$, this norm is defined as

$$\|p\|_{(\rho)} = \max_{\vartheta \in [0, \pi]} \sqrt{\Omega^{ab}p_a(\rho, \vartheta)p_b(\rho, \vartheta)} = \max_{\vartheta \in [0, \pi]} \sqrt{p(\rho, \vartheta)\bar{p}(\rho, \vartheta)}.$$  

(6.18)

In a first instance, we expect the following behaviour

$$\|A - 1\|_{(\rho)} = O\left(\frac{1}{\rho}\right), \quad \|q\|_{(\rho)} = O\left(\frac{1}{\rho^2}\right), \quad \|p\|_{(\rho)} = O\left(\frac{1}{\rho^2}\right)$$  

(6.19)

for all of the solutions above according to Result 2. Fig. 2 shows that the numerical solutions are indeed consistent with this. The particular numerical solution shown there was produced with $\varepsilon = 10^{-2}$, an absolute and relative error tolerance for the adaptive ODE solver of $10^{-12}$, and for $N = 11$, where $N$ is the number of spatial points in the $\vartheta$-direction. We have repeated the same numerical experiments with smaller values of $\varepsilon$ as well and found the same qualitative behaviour in agreement with Result 2.
However, in order to be demonstrate full consistency with Result 2 we must show that

\[ A = 1 + \frac{A^{(1)}}{\rho} + O \left( \frac{1}{\rho^2} \right), \]  

(6.20)

for a constant \( A^{(1)} \) (which then represents the ADM mass). We proceed as follows to numerically support the claim that this is indeed true. If the first two orders of \( A \) are constant with respect to \( \vartheta \), then the quantity, see Eqs. (A.9) and (A.10),

\[
1 - \frac{4\pi |A(\rho)|^2}{\|A(\rho)\|_{L^2(S^2)}} = \|A(\rho)\|_{L^2(S^2)} - \frac{4\pi |A(\rho)|^2}{\|A(\rho)\|_{L^2(S^2)}} = \sum_{\ell=1}^{\infty} |A_\ell(\rho)|^2 \sum_{\ell=0}^{\infty} |A_\ell(\rho)|^2
\]

(6.21)

must decay like \( O(\rho^{-4}) \). In Fig. 3 we see that this is indeed the case for \( \varepsilon = 10^{-2} \).

Let us now discuss how we numerically calculate the ADM mass. In accordance with Result 2, we have

\[ A(\rho) = 1 + \frac{A^{(1)}}{\rho} + O \left( \frac{1}{\rho^2} \right), \]  

(6.22)

see Eq. (A.8). Since \( A^{(1)} = A^{(1)} \) follows from the above, we therefore find

\[ A^{(1)} = \rho (A(\rho) - 1) + O \left( \frac{1}{\rho} \right). \]  

(6.23)

This suggests that we define

\[ m_N(\rho) = \rho (A(\rho) - 1), \]  

(6.24)
as a numerical estimate for the ADM mass $m_{ADM}$. In particular, we get

$$m_N(\rho) = m_{ADM} + O \left( \frac{1}{\rho} \right), \quad (6.25)$$

as confirmed by Fig. 4. Given all this it becomes clear that the numerical estimate for the mass $m_N$ becomes better as $\rho$ becomes large. We find, however, that the numerical errors in numerically solving the constraints becomes significant if we go further than $\rho \sim 10^3$. It is natural then to wonder how good the approximation $m_{ADM} = m_N(10^3)$ is. For this we consider the quantity

$$\mathcal{E}_A[m_{ADM}] = |m_N(2\rho) - m_N(\rho)|, \quad (6.26)$$

which is calculated for $\rho = 10^3$ as a measure of the absolute error. For our example case, with $\epsilon = 10^{-2}$, we find

$$m_{ADM} = 0.9942, \quad \mathcal{E}_A[m_{ADM}] = 2.34 \times 10^{-6}. \quad (6.27)$$

Notice that the relative error is of order $\sim 10^{-6}$. As was mentioned above, this is likely due to the error associated with measuring $m_{ADM}$ at a finite value of $\rho$. However, due to the errors generated by numerically solving the constraints for very large values of $\rho$, we need to accept whatever error we have at that point in the measurement of the mass.

### 6.4 Binary black hole-like initial data sets

In this subsection we repeat essentially the same numerical experiments as before with two changes: (1), the background data set is now determined with parameters $M_+ = M_- = 1/2$ and $Z = 1$ (an “equal mass binary black hole case”), and (2), instead of the “perturbed” Cauchy data as in Eq. (6.11), we now choose the values obtained from the background data set at $\rho_0 = 3$.

Our numerical findings, as shown in Fig. 5, are again consistent with the prediction

$$\|A - 1\| (\rho) = O \left( \frac{1}{\rho} \right), \quad \|q\| (\rho) = O \left( \frac{1}{\rho^2} \right), \quad \|p\| (\rho) = O \left( \frac{1}{\rho^2} \right) \quad (6.28)$$

from Result 2. Similarly, as with the single black hole case, we expect the quantity

$$\frac{\sum_{\ell=1}^{\infty} |A_{\ell}(\rho)|^2}{\sum_{\ell=0}^{\infty} |A_{\ell}(\rho)|^2} \quad (6.29)$$

to decay like $O(\rho^{-4})$. In Fig. 6 we observe exactly this behaviour. As before, we interpret this as strong evidence that the obtained vacuum initial data sets are indeed asymptotically flat. One may therefore use Eq. (6.24) to numerically estimate the ADM mass. We find

$$m_{ADM} = 0.9423, \quad \mathcal{E}_A[m_{ADM}] = 5.01 \times 10^{-6}. \quad (6.30)$$
We have repeated the calculations for similar parameter sets and came to the same conclusions: The resulting vacuum initial data sets are always asymptotically flat. Given fixed values of $M_+$ and $M_-$, say, $M_+ = M_- = 1/2$ as before, one expects the resulting ADM masses to dependent strongly on the separation distance $Z$. To investigate this we numerically calculate the resulting vacuum initial data sets and ADM masses for a range of separation distances $Z$. Note that since we treat $\rho_0 = 3$ as fixed, Eq. (6.7) introduces an upper bound for the possible values for $Z$, namely $Z < \rho_{\text{crit}}$. The results are shown in Fig. 8, where we see that the ADM mass is a decreasing function of the separation distance $Z$. Notice that same dependence of the ADM-mass on $Z$ had been observed in [12] for asymptotically Euclidean data sets.

7 Conclusions

In this paper we propose a new parabolic-hyperbolic formulation of the Einstein vacuum constraints based on a formulation originally given by Rácz. Using analytical and numerical methods we provide strong evidence that the main major drawback of these kinds of evolutionary formulations, namely to generically produce vacuum initial data sets which violate asymptotically flatness [10,12,19], has now finally been overcome.

In Sections 6.3 and 6.4 we have numerically constructed particular vacuum initial data sets as solutions of our new equations which could potentially be interpreted as perturbed Schwarzschild initial data and as binary black hole initial data, respectively. However, in order to investigate that these initial data sets really represent black holes, we would need to perform additional studies, like finding apparent horizons in the strong field regimes. This has not been done here. We emphasise that the formulation of the equations which we propose here is no obstacle to this. As it was noted in [12] it is rather our particular choices discussed in Section 6.1 which are not well-suited for studying the strong field regime. The
Figure 6: Mode decay plot of the numerical solution for the “binary black hole case” obtained with the same parameters as Fig. 5.

reason for this is the restriction $\rho > \rho_{\text{crit}}$ with $\rho_{\text{crit}}$ given in Eq. (6.7) and the fact that the parabolicity condition Eq. (3.6) in the case of 2-sphere foliations requires us to integrate outwards towards spacelike infinity. This restricts how much of the “interior geometry” can be accessed in our data sets. We have so far not investigated any remedies for this since our primary concern in this paper is the asymptotic behaviour at spacelike infinity.

Appendices

A Spin-weight and spin-weighted spherical harmonics

We say that a function $f$ defined on $S^2$ has spin-weight $s$ if it transforms as $f \rightarrow e^{is\xi}f$ under a local rotation by an angle $\xi$ in the tangent plane at any point in $S^2$. Let $(\theta, \phi)$ be standard polar coordinates on $S^2$. If $f$ has spin-weight $s$ and is sufficiently smooth, it can be written as

$$f(\theta, \phi) = \sum_{l=|s|}^{\infty} \sum_{m=-l}^{l} f_{lm} s Y_{lm}(\theta, \phi),$$

(A.1)
where $sY_{lm}(\theta, \varphi)$ are the spin-weighted spherical harmonics (SWSH) and where $f_{lm}$ are complex numbers. Using the conventions in [7–11, 29], these functions satisfy

$$
\int_{S^2} sY_{lm_1}(\theta, \varphi) * sY_{lm_2}(\theta, \varphi) \, d\Omega = \delta_{l_1l_2} \delta_{m_1m_2},
$$

where $\delta_{lm}$ is the Kronecker delta and $d\Omega$ is the area element of the metric of the round unit sphere. Using this we find that the coefficients $f_{lm}$ in Eq. (A.1) can be calculated as

$$
f_{lm} = \int_{S^2} f(\theta, \varphi) * sY_{lm}(\theta, \varphi) \, d\Omega.
$$

The eth-operators $\partial$ and $\partial'$ are defined by

$$
\partial f = \partial_\theta f - \frac{i}{\sin \theta} \partial_\varphi f - sf \cot \theta, \quad \partial' f = \partial_\theta f + \frac{i}{\sin \theta} \partial_\varphi f + sf \cot \theta,
$$

for any function $f$ on $S^2$ with spin-weight $s$. We have

$$
\partial sY_{lm}(\theta, \varphi) = -\sqrt{(l-s)(l+s+1)} s_{l+1}Y_{lm}(\theta, \varphi),
$$

$$
\partial' sY_{lm}(\theta, \varphi) = \sqrt{(l+s)(l-s+1)} s_{l-1}Y_{lm}(\theta, \varphi),
$$

$$
\partial' \partial sY_{lm}(\theta, \varphi) = -(l-s)(l+s+1) sY_{lm}(\theta, \varphi).
$$

Thus, using the properties above it is easy to see that $\partial$ raises the spin-weight by one while $\partial'$ lowers it by one.
The average of a function $f$ with spin-weight 0 on $\mathbb{S}^2$ is defined by

$$f = \frac{1}{4\pi} \int_{\mathbb{S}^2} f \, d\Omega.$$  \hfill (A.8)

Expressing $f$ in terms of SWSH and using Eq. (A.2) it follows

$$f = \frac{1}{4\pi} \int_{\mathbb{S}^2} \sum_{l=0}^{\infty} \sum_{m=-l}^{l} f_{lm} Y_{lm}(\vartheta, \varphi) \, d\Omega,$$

$$= \sqrt{\frac{4\pi}{4\pi}} \int_{\mathbb{S}^2} \sum_{l=0}^{\infty} \sum_{m=-l}^{l} f_{lm} Y_{lm}(\vartheta, \varphi) \sqrt{0} Y_{00}(\vartheta, \varphi) \, d\Omega,$$

$$= \frac{1}{\sqrt{4\pi}} f_{00},$$

where we have used the fact that $0 Y_{00}(\vartheta, \varphi) = (4\pi)^{-1/2}$. Another quantity of interest is the $L^2$-norm with respect to the standard round metric on $\mathbb{S}^2$. The Parseval identity states that

$$\|f\|_{L^2(\mathbb{S}^2)}^2 = \sum_{l=0}^{\infty} \sum_{m=-l}^{l} |f_{lm}|^2.$$  \hfill (A.10)

Finally we notice that many quantities considered in this paper are axially symmetric and therefore do not depend on the angle $\varphi$. For such functions, all coefficients with $f_{lm}$ with $m \neq 0$ vanish and we use the following short-hand notation to write Eq. (A.1) as

$$f(\vartheta) = \sum_{l=|s|}^{\infty} f_{l} s Y_l(\vartheta).$$  \hfill (A.11)
