SCATTERING DIAGRAMS FOR GENERALIZED CLUSTER ALGEBRAS

LANG MOU

Abstract. We construct scattering diagrams for Chekhov–Shapiro’s generalized cluster algebras where exchange polynomials are factorized into binomials, generalizing the cluster scattering diagrams of Gross, Hacking, Keel and Kontsevich. They turn out to be natural objects arising in Fock and Goncharov’s cluster duality. Analogous features and structures (such as positivity and the cluster complex structure) in the ordinary case also appear in the generalized situation. With the help of these scattering diagrams, we show that generalized cluster variables are theta functions and hence have certain positivity property with respect to the coefficients in the binomial factors.

1. Introduction

We study generalized cluster algebras in the sense of Chekhov and Shapiro [CS14]. These algebras are generalizations of the (ordinary) cluster algebras introduced by Fomin and Zelevinsky [FZ02], allowing more general exchange polynomials (as opposed to only binomials) in mutations.

We will see that generalized cluster algebras can not only be studied in a similar way as cluster algebras [FZ02, FZ03, BFZ05, FZ07], but that they also naturally appear in the context of the cluster duality proposed by Fock and Goncharov [FG09]. A modified version of Fock and Goncharov’s cluster duality was formulated and proved by Gross, Hacking, Keel and Kontsevich in [GHKK18]. In this paper, we extend the scheme therein to study generalized cluster algebras.

Generalized cluster algebras come in a family containing ordinary cluster algebras. Each algebra in this family can be viewed as (a subalgebra of) the algebra of regular functions of a generalized $\mathcal{A}$-cluster variety. The (generalized version of) cluster duality says this family is in a sense dual to another family of generalized $\mathcal{X}$-cluster varieties. In this paper, we demonstrate this duality by reconstructing a family of generalized cluster algebras with principal coefficients $\mathcal{A}^{\text{prin}}$ from a general fibre of the corresponding dual family of $\mathcal{X}$-cluster varieties.

In the ordinary case, the reconstruction is done through a cluster scattering diagram, the main technical tool developed in [GHKK18], which is a mathematical structure associated to the dual $\mathcal{X}$-cluster variety. For our purpose of studying generalized cluster algebras, we construct generalized
cluster scattering diagrams. This is done by allowing more general wall-crossing functions on the initial incoming walls. It turns out that many features (such as the positivity property of wall-crossings and the cluster complex structure) in the ordinary case still hold in the generalized situation; see Theorem 6.31 and Theorem 7.10.

Using the techniques of scattering diagrams (and related objects such as broken lines) transplanted from [GHKK18], we are able to prove that generalized cluster monomials are theta functions. As a result, they have certain positivity property coming from that of the scattering diagram. We remark that this positivity is with respect to the coefficients appearing in the binomial factors of exchange polynomials, thus weaker than a conjectural positivity of Chekhov and Shapiro (Conjecture 8.13) with respect to the coefficients of exchange polynomials themselves; See Theorem 8.12 and Section 8.5 for the precise statements.

We next describe the contents of the paper in more detail.

1.1. Generalized cluster algebras. Our way of generalizing cluster algebras is slightly different from [CS14], in the way we deal with coefficients. In a sense, one can go from one formulation to the other, in particular when the coefficients are evaluated in some algebraically closed field; see Section 3.2, Section 3.5 and also Section 8.5. We replace Fomin and Zelevinsky’s binomial exchange relation

\[ x'_k x_k = p_k^+ \prod_{i=1}^n x_i^{[b_{ik}]} + p_k^- \prod_{i=1}^n x_i^{[-b_{ik}]} \]

with a more general polynomial exchange relation

\[ x'_k x_k = \prod_{j=1}^{r_k} \left( p_{k,j}^+ \prod_{i=1}^n x_i^{[b_{ik}/r_k]} + p_{k,j}^- \prod_{i=1}^n x_i^{[-b_{ik}/r_k]} \right) \]

We require the coefficients \( p_{k,j}^\pm \) (in some semifield \((\mathbb{P}, \oplus, \cdot)\)) to satisfy the normalized condition \( p_{k,j}^+ \oplus p_{k,j}^- = 1 \). The normalization makes mutations deterministic and a particular choice of coefficients named principal coefficients (as in [FZ07]) available in the generalized situation.

It turns out many algebraic and combinatorial features of cluster algebras are also inherited by generalized cluster algebras. The same finite type classification as for cluster algebras [FZ03] and the generalized Laurent phenomenon have already been obtained in [CS14]. We show that the dependence on coefficients in the generalized case behaves very much like the ordinary case [FZ07]. In particular, a generalized version of the separation formula, Theorem 3.20, is made available through an analogous notion of principal coefficients. The well-known sign coherence of \( c \)-vectors (see Section 3.3) is also extended to the generalized case in Proposition 3.17. We note that Nakanishi has a rather different version of normalized generalized cluster algebras with a certain reciprocal restriction in [Nak15] where some results on the structures of seeds parallel to [FZ07] were also established.

Another remarkable feature of an ordinary cluster algebra is the positivity of its cluster variables, i.e. they are all Laurent polynomials in the initial variables \( x_i \) and coefficients \( p_{k,i}^\pm \) with non-negative integer coefficients. This was proved by Lee and Schiffler [LS15] for skew-symmetric types and by Gross, Hacking, Keel, and Kontsevich [GHKK18] for the more general skew-symmetrizable types. We extend the positivity to our generalized case (see Theorem 3.8), showing that the Laurent expression of any cluster variable in \( x_i \) and \( p_{k,i}^\pm \) has non-negative integer coefficients. We note that the positivity obtained here is (in the reciprocal case) a weak form of a positivity conjecture of Chekhov and Shapiro (which we reformulated in Conjecture 8.13); see Remark 3.9 and Section 8.5.

1.2. Generalized cluster varieties. Let \( \mathbb{P} \) be a lattice of finite rank. Fix an algebraically closed field \( k \) of characteristic zero. The (ordinary) cluster varieties of Fock and Goncharov [FG09] are schemes of
the form

\[ V = \bigcup_s T_{L,s} \]

where each \( T_{L,s} \) is a copy of the torus \( L \otimes \mathbb{k}^* \) and they are glued together via birational maps called cluster mutations. Here \( s \) runs over a set of seeds (a seed roughly being a labeled basis of \( L \)) iteratively generated by mutations. A cluster mutation is give by the following birational map

\[ \mu_{(m,n)} : T_L \dashrightarrow T_L, \quad \mu^*_{(m,n)}(z^\ell) = z^\ell (1 + z^m)^{\langle \ell, n \rangle}, \quad \ell \in L^*, \]

for a pair of vectors \((n,m) \in L \times L^*\), where \( \langle \cdot, \cdot \rangle \) denotes the natural paring between \( L^* \) and \( L \). It has a natural dual by switching the roles of \( m \) and \( n \), \( \mu_{(n,-m)} : T_{L^*} \to T_{L^*} \). Glueing \( T_{L^*} \) via these maps gives the dual cluster variety \( V^\lor = \bigcup_s T_{L^*,s} \).

Depending on the types of seeds and mutations chosen, one obtains either Fock–Goncharov’s \( \mathcal{A} \)-cluster varieties or \( \mathcal{X} \)-cluster varieties, which are dual constructions as above. A cluster algebra \( \mathcal{A} \) can be embedded into the upper cluster algebra \( \overline{\mathcal{A}} \), defined to be the algebra of regular functions on the corresponding \( \mathcal{A} \)-variety, while the dual \( \mathcal{X} \)-variety encodes the so-called \( Y \)-variables; see Section 4.

One can actually encode coefficients in each cluster mutation, the above construction thus leading to families of cluster varieties. They mutate along with seeds under certain rules. In the \( \mathcal{A} \)-case, they mutate as \( Y \)-variables (see [FZ07] and [FG09]). In the \( \mathcal{X} \)-case, the mutation rule of the coefficients has been worked out by Bossinger, Frías-Medina, Magee and Nájera Chávez in [BFMMNC20]. We extend these dynamics of coefficients to the generalized situation for both the \( \mathcal{A} \)- and \( \mathcal{X} \)-cases. We define a generalized cluster mutation as

\[ \mu^* (z^\ell) = z^\ell \prod_{j=1}^r \left( t_j^- + t_j^+ z^m \right)^{\langle \ell, n \rangle}, \]

which depends on some coefficients \( t_j^\pm \) in \( \mathbb{k}^* \); see Section 4. Thus an ordinary cluster mutation can be viewed as a specialization of a generalized one. Generalized cluster varieties are then defined by glueing tori via the generalized mutations. We obtain two families of generalized cluster varieties

\[ \pi_\mathcal{A} : \mathcal{A} \to \text{Spec}(R), \quad \pi_\mathcal{X} : \mathcal{X} \to \text{Spec}(R), \]

where the coefficients vary in some torus \( \text{Spec}(R) = (\mathbb{G}_m)^d \).

One key observation of Gross, Hacking and Keel in [GHK15] is that a cluster variety can be investigated through its toric models, and mutations between seeds are basically switching between neighboring toric models. A toric model is a construction of a log Calabi–Yau variety by blowing up a hypersurface on the toric boundary of some toric variety. In the cluster situation, the toric variety depends on the choice of a seed \( s \) which also tells us where on the toric boundary to blow up. The resulting log Calabi–Yau variety is shown in [GHK15] (under certain nice conditions) to be isomorphic to the corresponding cluster variety up to codimension two subsets. We extend this description to the generalized case, for both \( \mathcal{A} \)- and \( \mathcal{X} \)-type varieties; see Theorem 5.4 and Section 5.3.

1.3. Scattering diagrams. Cluster scattering diagrams are the main technical tool in [GHKK18]. They have their origin in [KS06] and [GS11] in mirror symmetry. Roughly speaking, in the cluster case, a scattering diagram is a collection of walls in a real vector space with attached wall-crossing functions (some of them giving information on mutations). Similar to a cluster algebra which starts with one cluster with information to perform mutations in \( n \) directions iteratively, its scattering diagram can be constructed by initially setting up \( n \) incoming walls and letting them propagate, generating only outgoing walls.
To get a generalized cluster scattering diagram, we replace ordinary wall-crossings (which correspond to ordinary cluster mutations) on the initial incoming walls by the generalized ones of the form

\[ f = \prod_{j=1}^{r} (1 + t_j z^n) \]

where the \( t_j \) are treated as formal parameters. Given a seed \( s \) (in the generalized sense), the associated data of incoming walls uniquely determines a consistent scattering diagram \( D_s \), which we call the generalized cluster scattering diagram.

We show that the behavior of \( D_s \) under mutations is analogous to that of the ordinary case, in a way it is canonically associated to a mutation equivalence class of seeds. This is called the mutation invariance in [GHKK18, Theorem 1.24]. See Theorem 6.27 for the precise description of the following theorem.

**Theorem 1.1** (Theorem 6.27). There is a piecewise linear operation \( T_k \) such that \( T_k(D_s) \) is equivalent to \( D_{\mu_k(s)} \) where \( \mu_k(s) \) denotes the mutation in direction \( k \) of the seed \( s \).

In analogy with the ordinary case, the mutation invariance leads to the cluster complex structure of \( D_s \).

**Theorem 1.2** (Theorem 7.10). There is the cluster cone complex \( \Delta^+_s \) such that \( D_s \) is a union of codimension one cones of \( \Delta^+_s \) (with explicit attached wall-crossing functions) and walls outside \( \Delta^+_s \).

We observe in Lemma 6.19 that \( D_s \) is equivalent to the tropical vertex scattering diagram \( D(X, H) \) of Argüz and Gross [AG22] associated to the corresponding \( \mathcal{X} \)-type toric model associated to \( s \). It is shown in [AG22, Theorem 6.1] that \( D(X, H) \) is further equivalent (after a certain piecewise linear operation) to the canonical scattering diagram \( D(X, D) \) (see [GS22] and [AG22, Section 2]) of the log Calabi–Yau pair \((X, D)\) from the toric model. We thus see that \( D_s \) is canonically associated to the corresponding \( \mathcal{X} \)-cluster variety, with a different seed \( s' \) simply giving another representative \( D_{s'} \).

### 1.4. Cluster dualities

The cluster duality of Fock and Goncharov predicts that, in the ordinary case, the varieties \( \mathcal{A} \) and \( \mathcal{X} \) (see Section 4 for our convention as we do not need the Langlands dual data) are dual in the sense that the upper cluster algebra \( \widehat{\mathcal{A}} \) has a basis parametrized by the tropical set \( \mathcal{X}^{\text{trop}}(\mathbb{Z}) \) (see [GHKK18, Section 2] for a definition) and vice versa. A modified version of this duality (and when it is true) is the main subject of study of [GHKK18].

The strategy of [GHKK18] to get the desired basis is as follows. First the tropical set \( \mathcal{X}^{\text{trop}}(\mathbb{Z}) \) (resp. \( \mathcal{X}^{\text{trop}}(\mathbb{R}) \)) can be identified with the cocharacter lattice \( M \) (resp. \( \hat{M} := M \otimes \mathbb{R} \)) of a chosen seed torus \( T_{M, s} = M \otimes \mathbb{K}^\ast \) contained in the variety \( \mathcal{X} \). By the mutation invariance, the ordinary cluster scattering diagram \( D^\text{ord}_s \) (see Section 6.3) naturally lives in \( \mathcal{X}^{\text{trop}}(\mathbb{R}) \). Denote by \( \Delta^+ \) the set of integral points inside the cluster complex (which is again a canonical subset of \( \mathcal{X}^{\text{trop}}(\mathbb{Z}) \) by mutation invariance).

For any integral point \( m \in \mathcal{X}^{\text{trop}}(\mathbb{Z}) \), using the scattering diagram \( D^\text{ord}_s \), one can construct the theta function \( \vartheta_m \), which in general is only a formal power series in a completion \( \hat{\mathcal{M}}_s \) which depends on \( s \). However, it is shown in [GHKK18, Theorem 4.9] that for \( m \in \Delta^+ \), \( \vartheta_m \) is indeed a Laurent polynomial in \( \hat{\mathcal{M}}_s \) and corresponds to a cluster monomial. Furthermore, there is a canonically defined (i.e. independent of \( s \)) subset \( \Theta \) of \( \mathcal{X}^{\text{trop}}(\mathbb{Z}) \) containing \( \Delta^+ \) such that for any \( m \in \Theta \), \( \vartheta_m \) is a Laurent polynomial on every seed torus. It is also shown in [GHKK18] that the vector space

\[ \text{mid}(\mathcal{A}) := \bigoplus_{m \in \Theta} \vartheta_m \]

has an associative algebra structure whose structure constants are defined through broken lines. This algebra \( \text{mid}(\mathcal{A}) \) can be embedded in \( \widehat{\mathcal{A}} \) so that for \( m \in \Delta^+ \), \( \vartheta_m \) is sent to the corresponding cluster monomial. While we do not know in general when \( \text{mid}(\mathcal{A}) \) equals \( \widehat{\mathcal{A}} \) (see [GHKK18, Theorem 0.3]),
we do have a basis of \( \text{mid}(\A) \) parametrized by the subset \( \Theta \). Strictly speaking, this process is done through the principal coefficients case.

Our insight is that it is natural to consider the above cluster duality for generalized cluster varieties. In the principal coefficients case, we take a general fiber \( \A^\text{prin}_\lambda := \pi^{-1}_\lambda(\lambda) \) of the family

\[
\pi_\lambda : \A^\text{prin} \to \text{Spec}(R).
\]

The generalized cluster scattering diagram \( \mathcal{D}_s \) then lives in the tropical set \( (\A^\text{prin}_\lambda)^\text{trop}(\R) \) which is identified with \( M_R \) given a chosen seed \( s \). Towards a generalized version of the cluster duality, we show

**Theorem 1.3** (Theorem 8.12). For any \( m \in \Delta^+_s \), the theta function \( \vartheta_m \) constructed from the generalized cluster scattering diagram \( \mathcal{D}_s \) corresponds to the cluster monomial of the generalized cluster algebra \( \mathcal{A}^\text{prin}(s) \) whose \( g \)-vector is \( m \). Moreover, it is a Laurent polynomial in the initial cluster variables \( x_i \) and coefficients \( p_{i,j} \) with non-negative integer coefficients.

It follows from the above theorem that the family

\[
\pi_\lambda : \A^\text{prin} \to \text{Spec}(R)
\]

can be reconstructed from a general fibre \( \A^\text{prin}_\lambda \) (through any of its toric models); see Proposition 8.3.

In principle, in the generalized case, one could consider the subset \( \Theta \) as in [GHKK18] and the corresponding generalized middle cluster algebra \( \text{mid}(\A^\text{prin}) \). This would lead to a formulation of generalized cluster duality similar to the ordinary case in [GHKK18, Theorem 0.3]. Then the usual problem on when the full Fock–Goncharov conjecture is true remains and can be discussed as in [GHKK18, Section 8].

### 1.5. Relations to other works.

There are examples of generalized cluster scattering diagrams from representation theory, where they are realized as Bridgeland’s stability scattering diagrams [Bri17] for quivers (with loops) with potentials; see [LFM24] of Labardini-Fragoso and the author for such examples arising from surfaces with orbifold points.

In rank two, the scattering diagram \( \mathcal{D}_s \) has already appeared in [GPS10] and [GP10] from origins other than cluster algebras. There the wall-crossing functions are shown to encode relative Gromov–Witten invariants on certain log Calabi–Yau surfaces. Some conjectural wall-crossing functions in [GP10] are later verified in [RW13] using techniques from quiver representations; see Example 6.22.

The recent paper [CKM23] of Cheung, Kelley and Musiker (outlined in [CKM21]) and some part of Kelley’s PhD thesis [Kel21] have significant overlaps with this paper and the author’s PhD thesis [Mou20, Chapter 8]. We in the following highlight the differences and relationships concerning scattering diagrams.

In [Mou20, Chapter 8], a class of generalized cluster scattering diagrams were constructed and properties including mutation invariance and cluster complex structure were proved. In that work, a palindromic and monic restriction (termed reciprocal in [CS14]) on the coefficients was imposed. Such a scattering diagram can be obtained from applying to \( \mathcal{D}_s \) of the current paper an evaluation \( \lambda \) such that the initial wall-crossings are specialized to reciprocal polynomials, i.e., of the form

\[
f = 1 + a_1 z^w + \cdots + a_{r-1} z^{(r-1)w} + z^{rw}
\]

where \( r \in \Z_{\geq 0} \), \( w \in M \), and \( a_k = a_{r-k} \) in some ground field \( k \); see Section 6.4. Scattering diagrams almost identical to these (with the reciprocal restriction) were later considered by Cheung, Kelley and Musiker in the announcement [CKM21], with more details provided in [Kel21]. The authors treat the coefficients \( a_i \) as formal variables. They also outlined the construction of theta functions, following [GHKK18].
The current paper aims to fill in gaps and missing details in [Mou20], enhance the setup therein to include more general coefficients, and discuss the positivity of generalized cluster algebras using scattering diagram techniques. Shortly after this paper was posted on the arXiv, [CKM23] appeared on the arXiv, completing the program [CKM21]. Despite many similarities between the current paper and [CKM23], our approaches of treating coefficients differ somewhat. In [CKM23], the y-variables in a generalized seed and the coefficients \( a = (a_i) \) in a generalized exchange polynomial are treated separately. The coefficients \( a \) are assumed to be reciprocal and remain unchanged under mutations. In contrast, we view the coefficients \( a \) as deriving from the y-variables (denoted as \( p \) in our notation) by factorizing an exchange polynomial into binomials, with each binomial governed by one coefficient in the style of Fomin and Zelevinsky. This approach allows us to realize more general exchange polynomials (beyond just reciprocal ones), at least for an algebraically closed ground field, by specialization from principal coefficients (see Section 3.5 and Section 8.5). This setup also enables us to formulate and prove a form of positivity for generalized cluster algebras, a topic not extensively discussed in [CKM23].

Acknowledgements

I would like to thank Daniel Labardini-Fragoso for showing me an example of generalized cluster scattering diagram in the beginning; Fang Li and Siyang Liu for helpful discussions and the hospitality during my visit at Zhejiang University. During the preparation of the manuscript, I was supported by the Royal Society through the Newton International Fellowship NIF\R1\201849.

2. Preliminaries

In this section, we review some preliminaries commonly used in the theory of cluster algebras [FZ02].

2.1. Semifields.

Definition 2.1. A semifield \((P, \oplus, \cdot)\) is a torsion free (multiplicative) abelian group \(P\) with a binary operation \(\oplus\) which is commutative, associative and distributive.

We denote by \(ZP\) the group ring of \(P\) and by \(\mathbb{N}P \subset ZP\) the subset of linear combinations with coefficients in \(\mathbb{N}\). Denote by \(QP\) the field of fractions of \(ZP\).

For an element \(p \in P\), we define in \(P\) two elements:

\[
p^+ := \frac{p}{p \oplus 1} \quad \text{and} \quad p^- := \frac{1}{p \oplus 1}.
\]

Definition 2.2. Let \(I\) be a finite set. We define \(\text{Trop}(s_i \mid i \in I)\) to be the (multiplicative) abelian group with free generators \(s_i\) indexed by \(I\), with the operation addition \(\oplus\):

\[
\prod_{i \in I} s_i^{a_i} \oplus \prod_{i \in I} s_i^{b_i} := \prod_{i \in I} s_i^{\min(a_i, b_i)}.
\]

It is clear that \(\text{Trop}(s_i \mid i \in I)\) is a semifield. Such a semifield is called a tropical semifield.

For \(n \in \mathbb{Z}\), we write \([n]_+ := \max\{n, 0\}\). The elements \(s^\pm\) for

\[
s = \prod_{i \in I} s_i^{a_i} \in \text{Trop}(s_i \mid i \in I)
\]

has the following simple expressions:

\[
s^+ = \prod_{i \in I} s_i^{[a_i]_+} \quad \text{and} \quad s^- = \prod_{i \in I} s_i^{[-a_i]_+}.
\]

Definition 2.3. Denote by \(Q_{sf}(u_1, \ldots, u_l)\) the set of all rational functions in \(l\) independent variables which can be written as subtraction-free rational expressions in \(u_1, \ldots, u_l\). Then the set \(Q_{sf}(u_1, \ldots, u_l)\) is a semifield with respect to the usual addition and multiplication.
We call such $\mathbb{Q}_sf(u_1, \ldots, u_l)$ a universal semifield since for another arbitrary semifield $\mathbb{P}$ and its elements $p_1, \ldots, p_l$, there exists a unique map of semifields from $\mathbb{Q}_sf(u_1, \ldots, u_l)$ to $\mathbb{P}$ sending $u_i$ to $p_i$; see [BFZ96, Lemma 2.1.6].

2.2. Mutations of matrices.

**Definition 2.4.** A matrix $B \in \text{Mat}_{n \times n}(\mathbb{Z})$ is called (left) skew-symmetrizable if there exists a diagonal matrix $D = \text{diag}(d_i \mid 1 \leq i \leq n)$ with $d_i \in \mathbb{Z}_{>0}$ such that

$$DB + (DB)^T = 0.$$

Such a matrix $D$ is called a (left) skew-symmetrizer of $B$.

**Definition 2.5 ([FZ02, Definition 4.2]).** Let $B = (b_{ij}) \in \text{Mat}_{n \times n}(\mathbb{Z})$ be a skew-symmetrizable matrix. For $k = 1, \ldots, n$, we define $\mu_k(B) = (b'_{ij}) \in \text{Mat}_{n \times n}(\mathbb{Z})$ the mutation of $B$ in direction $k$ by setting

1. $b'_{ik} = -b_{ik}$ and $b'_{kj} = -b_{kj}$ for $1 \leq i, j \leq n$;
2. For $i \neq k$ and $j \neq k$,

$$b'_{ij} = \begin{cases} b_{ij} + b_{ik}b_{kj} & \text{if } b_{ik} > 0 \text{ and } b_{kj} < 0; \\ b_{ij} - b_{ik}b_{kj} & \text{if } b_{ik} < 0 \text{ and } b_{kj} > 0; \\ b_{ij} & \text{otherwise}. \end{cases}$$

It is clear that the matrix $\mu_k(B)$ is again skew-symmetrizable with the same set of skew-symmetrizers of $B$. One can easily check that a mutation is involutive in the same direction, i.e., $\mu_k \circ \mu_k(B) = B$.

3. Generalized cluster algebras

3.1. Generalized cluster algebras. Cluster algebras were originally invented by Fomin and Zelevinsky in [FZ02], which we later refer to as ordinary cluster algebras. A generalization of cluster algebras has been provided by Chekhov and Shapiro in [CS14]. Our definition of generalized cluster algebras below may be considered as a special case (of a slight generalization) of theirs but with a normalization analogous to the one in [FZ02, Definition 5.3] for ordinary cluster algebras. The relation and difference will be explained in Section 3.2.

We follow the pattern of [FZ07] to define generalized cluster algebras. Most of the key notions here are the generalized versions of their counterparts in the ordinary case.

**Definition 3.1.** A (generalized) labeled seed $\Sigma$ of rank $n \in \mathbb{N}$ is a triple $(x, p, B)$, where

- $p = (p_1, \ldots, p_n)$ is an $n$-tuple of collections of elements, where each $p_i = (p_{i,1}, \ldots, p_{i,r_i})$ is a $r_i$-tuple of elements in a semifield $(\mathbb{P}, \oplus, \cdot)$ for some positive integer $r_i$.
- $x = \{x_1, \ldots, x_n\}$ is a collection of algebraically independent rational functions of $n$ variables over $\mathbb{Q}\mathbb{P}$. In other words, the $x_1, \ldots, x_n$ are elements in some field of rational functions $\mathcal{F} = \mathbb{Q}\mathbb{P}(u_1, \ldots, u_n)$ such that $\mathcal{F} = \mathbb{Q}\mathbb{P}(x_1, \ldots, x_n)$.
- $B \in \text{Mat}_{n \times n}(\mathbb{Z})$ is skew-symmetrizable such that for any $i = 1, \ldots, n$, its $i$-th column is divisible by $r_i$. The diagonal matrix $D = \text{diag}(r_i)$ is not necessarily a skew-symmetrizer of $B$.

For convenience, let $I$ be the index set $\{1, \ldots, n\}$. For an arbitrary positive integer $k$, we use the interval $[1,k]$ to represent the set $\{1, \ldots, k\}$. We will often call a labeled seed simply a seed if there is no confusion.

Associated to a labeled seed $\Sigma = (x, p, B)$, for each $i \in I$, there is the exchange polynomial

$$\theta_i(u, v) = \theta(p_i)(u, v) := \prod_{l=1}^{r_i} (p_{i,l}^+ u + p_{i,l}^- v) \in \mathbb{Z}\mathbb{P}[u, v].$$
Write $\beta_{ij} = b_{ij}/r_j \in \mathbb{Z}$. We put

$$u_{j,+} := \prod_{i : b_{ij} > 0} x_i^b_{ij}, \quad u_{j,-} := \prod_{i : b_{ij} < 0} x_i^{-b_{ij}}$$

and

$$p_{i,+} := \prod_{l=1}^{r_i} p_{i,l}^+, \quad p_{i,-} := \prod_{l=1}^{r_i} p_{i,l}^- \in \mathbb{P}.$$ 

Note that all the above notions are with respect to $\Sigma$.

**Definition 3.2.** For any $k \in I$, we define the *mutation of a seed* $\Sigma = (\mathbf{x}, \mathbf{p}, B)$ in direction $k$ as a new labeled seed $\mu_k(\mathbf{x}, \mathbf{p}, B) := ((x'_i), (p'_i), B')$ where $p'_i = (p'_{i,j} \mid j \in [1, r_i])$ in the following way:

1. $B' = \mu_k(B)$;
2. $p'_{k,j} = p_{k,j}^{-1}$ for $j \in [1, r_k]$;
3. for $i \neq k$, $j \in [1, r_i]$

$$p'_{i,j} = \begin{cases} p_{i,j} \cdot (p_{k,-})^\beta_{ki} & \text{if } \beta_{ik} > 0 \\ p_{i,j} \cdot (p_{k,+})^\beta_{ki} & \text{if } \beta_{ik} \leq 0, \end{cases}$$

or equivalently

$$\text{for } i \neq k, \quad p'_{i,j} = p_{i,j} \left( \prod_{l=1}^{r_i} \left( 1 + p_{k,l}^{\text{sgn}(\beta_{ik})} \right) \right)^{-\beta_{ki}}.$$

4. $x'_i = \begin{cases} x_i & \text{if } i \neq k \\ x_k^{-1} \theta[p_k](u_{k,+}, u_{k,-}) & \text{if } i = k. \end{cases}$

**Lemma 3.3.** The mutation $\mu_k$ is involutive, i.e. $\mu_k \circ \mu_k(\Sigma) = \Sigma$.

**Proof.** We check that $\mu_k$ is involutive on each component of a seed. We denote $\mu_k \circ \mu_k(\Sigma) = ((x''_i), (p''_i) \mid j \in [1, r_i])$, $B'')$.

For this seed, we simply denote the relevant objects appearing in Definition 3.2 by adding a double prime to the old symbols, while for $\mu_k(\Sigma)$, we add a single prime.

1. First of all, the matrix mutation $\mu_k$ is an involution, which was already shown in [FZ02].
2. We have for $j \in [1, r_k]$,

$$p''_{k,j} = (p'_{k,j})^{-1} = p_{k,j}.$$ 

3. For $i \neq k$, we have for $j \in [1, r_i]$,

$$p''_{i,j} = \begin{cases} p'_{i,j} \cdot (p'_{k,-})^\beta_{ki} & \text{if } \beta_{ik} > 0 \\ p'_{i,j} \cdot (p'_{k,+})^\beta_{ki} & \text{if } \beta_{ik} \leq 0, \end{cases}$$

and

$$= \begin{cases} p_{i,j} \cdot (p_{k,+})^\beta_{ki} \cdot (p'_{k,-})^{-\beta_{ki}} & \text{if } \beta_{ik} < 0 \\ p_{i,j} \cdot (p_{k,-})^\beta_{ki} \cdot (p'_{k,+})^{-\beta_{ki}} & \text{if } \beta_{ik} \geq 0. \end{cases}$$

The last equality is because $p'_{k,+} = p_{k,-}$ and $p'_{k,-} = p_{k,+}$.
(4) Finally for the $x$ part, we have

$$x''_i = \begin{cases} 
  x'_i & \text{if } i \neq k \\
  (x'_k)^{-1} \theta[p'_k] \left( u'_{k:+}, u'_{k:-} \right) & \text{if } i = k 
\end{cases}$$

$$= \begin{cases} 
  x_i & \text{if } i \neq k \\
  x_k \cdot \theta[p_k] \left( u_{k:+}, u_{k:-} \right)^{-1} \theta[p'_k] \left( u'_{k:+}, u'_{k:-} \right) & \text{if } i = k 
\end{cases} = x_i.
$$

The last equality is because that $\theta[p'_k](u, v) = \theta[p_k](v, u)$ and $u'_{k:\pm} = u_{k:\mp}$.

So overall we have proven that $\mu_k \circ \mu_k(\Sigma) = \Sigma$. \hfill \square

Fix a positive integer $n$. We consider the (non-oriented) $n$-regular tree $T_n$ whose edges are labeled by the numbers $1, \ldots, n$ as in [FZ02]. Lemma 3.3 makes the following definition well-defined.

**Definition 3.4.** A (generalized) cluster pattern is an assignment of a labeled seed $\Sigma_t = (x_t, p_t, B^t)$ to every vertex $t \in T_n$, such that for any $k$-labeled edge with endpoints $t$ and $t'$, the seed $\Sigma_{t'}$ is the mutation in direction $k$ of $\Sigma_t$, i.e. $\Sigma_{t'} = \mu_k(\Sigma_t)$.

The elements in $\Sigma_t$ are written as follows:

$$x_t = (x_{i,t} \mid i \in I), \quad p_{i,t} = (p_{i,j,t} \mid j \in [1, r_i]), \quad B^t = (b_{ij}).$$

The part $x$ of a labeled seed is called a (labeled) cluster, elements $x_i$ are called cluster variables, elements $p_{i,j}$ are called coefficients and $B$ is called exchange matrix.

Two seeds are mutation-equivalent if one is obtained from the other by a sequence of mutations. If a seed $\Sigma$ appears in a cluster pattern, then by definition any seeds mutation-equivalent to $\Sigma$ must also appear. On the other hand, assigning a seed of rank $n$ to any vertex of $T_n$ would uniquely determine a cluster pattern.

By definition, all cluster variables live in some ambient field $\mathcal{F}$ of rational functions of $n$ variables. One may identify $\mathcal{F}$ with $\mathbb{Q}P(x_1, \cdots, x_n)$ where $(x_1, \ldots, x_n)$ is a cluster.

**Definition 3.5.** Given a generalized cluster pattern, the (generalized) cluster algebra $\mathcal{A}$ is defined to be the $\mathbb{Z}$-subalgebra of the ambient field $\mathcal{F}$ generated by all cluster variables $x_{i,t}$ in all seeds that appear in the cluster pattern. Since a cluster pattern is determined by any of its seed, we denote $\mathcal{A} = \mathfrak{a}(\Sigma)$ where $\Sigma = (x, p, B)$ is any seed in this cluster pattern.

**Remark 3.6.** In the case where $r_i = 1$ for any $i \in I$, all the above generalized notions recover the original versions of Fomin and Zelevinsky [FZ07].

For convenience, one can specify one vertex $t_0 \in T_n$ to be initial, thus the associated seed being called the initial seed with the initial cluster, cluster variables, coefficients and exchange matrix. All other seeds are obtained by applying mutations iteratively to the initial one. For the following two theorems, we denote by $(x_1, \ldots, x_n)$ the initial cluster.

**Theorem 3.7** (Generalized Laurent phenomenon, cf. [FZ02] and [CS14]). Let $(x, p, B)$ be a generalized labeled seed. Then any cluster variable of $\mathcal{A}(x, p, B)$ is a Laurent polynomial over $\mathbb{Z}$ in the initial cluster variables $x_i$, i.e. an element in $\mathbb{Z}[x_1^\pm, \ldots, x_n^\pm]$.

**Proof.** The generalized Laurent phenomenon was already obtained in [CS14, Theorem 2.5]. Since our setting is slightly different, we give a proof for completeness.
The proof completely follows from the discussion in [FZ02, Section 3]. The generalized Laurent property is a direct corollary of [FZ02, Theorem 3.2]. One only needs to check the following hypothesis required by [FZ02, Theorem 3.2]: for any subgraph $t_0 \overset{i}{\rightarrow} t_1 \overset{j}{\rightarrow} t_2 \overset{i}{\rightarrow} t_3$

in the tree $T_n$, if we define the following three exchange polynomial in $n$ variables $x_1, \ldots, x_n$ by writing

$$P(x_{t_0}) = \theta[p_{i,t_0}][u^i_{t_0}, u^i_{t_0}], \quad Q(x_{t_1}) = \theta[p_{j,t_1}][u^j_{t_1}, u^j_{t_1}], \quad R(x_{t_2}) = \theta[p_{i,t_2}][u^i_{t_2}, u^i_{t_2}],$$

then they satisfy $R = C \cdot (P|_{x_j = q_0/x_j})$ where $Q_0 = Q|_{x_j = 0}$ for some $C \in \mathbb{N}[x_1, \ldots, x_n]$. Notice that since $t_0 \overset{i}{\rightarrow} t_1$, we have

$$P = \prod_{i=1}^{r_i} \left( p_{i,l,t_1} \prod_k x_k^{[\beta^i_{l_1}]+} + p_{i,l,t_1} \prod_k x_k^{-[\beta^i_{l_1}]+} \right).$$

When $\beta^i_{l_1} = 0$, $\beta^j_{l_1} = -\beta^i_{l_1} = 0$. So $x_j$ does not appear in $P$, implying $P = P|_{x_j = q_0/x_j}$. In this case, we have for any $l \in [1, r_i]$

$$p_{i,l,t_0} = p_{i,l,t_2}, \quad \beta^j_{l_1} = -\beta^i_{l_1}.$$

Thus we have $R = P$.

When $\beta^i_{l_1} < 0$ (implying $\beta^j_{l_1} > 0$), then

$$Q_0/x_j = p_{j,l+t_1} x_j^{-1} \prod_k x_k^{[\beta^j_{l_1}]}$$

and

$$P|_{x_j = q_0/x_j} = \prod_{i=1}^{r_i} \left( p_{i,l,t_1} p_{j,l+t_1} x_j^{-[\beta^j_{l_1}]+} \prod_k x_k^{[\beta^i_{l_1}]+} + p_{i,l,t_1} x_j^{[\beta^j_{l_1}]+} \prod_k x_k^{-[\beta^i_{l_1}]+} \right).$$

We take the ratio of the two monomials in each factor of the above product to obtain monomials

$$p_{i,l,t_1} p_{j,l+t_1} x_j^{[\beta^j_{l_1}]+} \prod_k x_k^{[\beta^i_{l_1}]}.$$

We get exactly the same monomials if we do the same for $R$. So $R$ and $P|_{x_j = q_0/x_j}$ only differ by a monomial factor in $\mathbb{N}[x_1, \ldots, x_n]$. The case when $\beta^i_{l_1} > 0$ is analogous. Hence the hypothesis is checked and the Laurent phenomenon follows from [FZ02, Theorem 3.2].

The following Theorem 3.8 is a generalization of the well-known positivity for ordinary cluster algebras. In the case of ordinary cluster algebras, the positivity was originally conjectured by Fomin and Zelevinsky [FZ02]. It has been proved by Lee and Schiffler [LS15] when the exchange matrix $B$ is skew-symmetric and by Gross, Hacking, Keel, and Kontsevich [GHKK18] when $B$ is more generally skew-symmetrizable.

**Theorem 3.8 (Positivity).** In a generalized cluster algebra, each of the coefficients in the Laurent polynomial corresponding to any cluster variable from Theorem 3.7 is a non-negative integer linear combination of elements in $\mathbb{P}$. In other words, any cluster variable is an element in $\mathbb{N}[x_1^\pm, \ldots, x_n^\pm]$.

**Proof.** By the separation formula Theorem 3.20 and Remark 3.21, we only need to show the positivity in the principal coefficients case (to be defined in Definition 3.13). In this case, we prove the positivity in Theorem 8.12. □

**Remark 3.9.** Chekhov and Shapiro conjectured [CS14, Conjecture 5.1] a positivity for generalized cluster algebras under a reciprocal condition; see also the formulation in Conjecture 8.13. In the reciprocal case, this positivity implies Theorem 3.8. We do not know how to show this stronger positivity in general; see the discussion in Section 8.5.
3.2. Relation to Chekhov–Shapiro’s definition. In [CS14], Chekhov and Shapiro defined generalized cluster algebras by considering more general exchange polynomials. Precisely, a labeled seed in that setting is a triple $(\mathbf{x}, \Pi, B)$ where $\mathbf{x}$ and $B$ are the same as in Definition 3.1 and $\Pi_i = (\alpha_{i,k} \in \mathbb{P} | 0 \leq k \leq r_i)$ for $i \in I$. Here we only take $\mathbb{P}$ as a multiplicative abelian group. The coefficients $\alpha_{i,k}$ are responsible for expressing the exchange polynomial defined as

$$\theta_i(u,v) := \sum_{k=0}^{r_i} \alpha_{i,k} u^{r_i-k} v^k \in \mathbb{Z}[u,v].$$

The mutation $(\mathbf{x}', \Pi', B') = \mu_k(\mathbf{x}, \Pi, B)$ is defined in the following way.

1. $B' = \mu_k(B)$;
2. $\alpha'_{i,j} = \alpha_{k,r_k-j}$ and for $i \neq k$, the coefficients satisfy
   $$\alpha'_{i,j}/\alpha_{i,0} = \begin{cases} 
   \alpha_{i,j}/\alpha_{i,0} & \text{if } \beta_{ik} > 0 \\
   \alpha_{i,j}/\alpha_{i,0} & \text{if } \beta_{ik} \leq 0;
   \end{cases}$$
3. $x'_i = x_i$ for $i \neq k$ and $x_k'x_k = \theta_i (u_{k,+}, u_{k,-}).$

Remark 3.10. In this setting, it does no harm to allow the coefficients $\alpha_{i,k}$ to be elements of $\mathbb{Z}[P]$, as long as the above rule (2) is satisfied. For example, one may check that the Laurent phenomenon still holds for cluster variables.

Now assume the multiplicative abelian group $\mathbb{P}$ has an addition $\oplus$ so that it is a semifield. In our setting the exchange polynomials are given by $\theta[\mathbf{p}_i](u,v)$, thus the coefficients $\alpha_{i,j}$ corresponding to the coefficients of $\theta[\mathbf{p}_i](u,v)$ when expanded as polynomial of $u$ and $v$. Under Definition 3.2, the polynomials $\theta[\mathbf{p}_i](u,v)$ mutate in a way satisfying the rule (2) above. In fact, when talking about coefficients $\alpha_{i,j}/\alpha_{i,0}$, we can normalize our polynomial

$$\tilde{\theta}[\mathbf{p}_i](u,v) = \prod_{j \in [1, r_i]} (p_{i,j}u + v).$$

So when expanded as a sum of monomials in $u$ and $v$, the coefficients of $\tilde{\theta}[\mathbf{p}_i]$ are $\prod_{j \in J} p_{i,j}$ for a subset $J \subset [1, r_i]$. According to the mutation formula in Definition 3.2, under $\mu_k$, we have

$$\prod_{j \in J} p'_{i,j} = p'_{k,\pm} \prod_{j \in J} p_{i,j},$$

which satisfies the rule (2). So our definition of generalized cluster algebras can be viewed as a special case of [CS14] if we ease the condition $\alpha_{i,k} \in \mathbb{P}$ into $\alpha_{i,k} \in \mathbb{Z}[P]$.

We note that the above rule (2) in [CS14] is not enough to uniquely determine the coefficients $(\Pi'_i)$ after mutation, whereas the mutation formula in Definition 3.2 is deterministic because of the normalization condition $p'_{k,j} \oplus p'_{k,j-1} = 1$.

One advantage of our definition is the availability of principal coefficients analogous to [FZ07, Definition 3.1], to be discussed in the next section.

3.3. Principal coefficients. As in [FZ07] for ordinary cluster algebras, we have the notion of principal coefficients for generalized cluster algebras.

Definition 3.11. We say a generalized cluster algebra $\mathcal{A}$ is of geometric type if $\mathbb{P}$ is a tropical semifield

$$\text{Trop}(s_a | a \in I')$$

where $I'$ is a finite index set.
Proposition 3.12. Let $\mathcal{A}$ be a generalized cluster algebra of geometric type. For each seed $\Sigma$ in $\mathcal{A}$’s cluster pattern and $i \in I$, we introduce matrices

$$C^{(i)} = e^{(i)}_{\Sigma} = \left( e_{a,j}^{(i)} \right) \in \text{Mat}_{|I'| \times |r_i|}(\mathbb{Z})$$

to encode the coefficients $p_{i,j}$ by columns of $C^{(i)}$:

$$p_{i,j} = \prod_{a \in I'} c_{a}^{(i)} \in \mathbb{P}.$$ 

Denote by $\left( e_{a,j}^{(i)} \right)$ the matrices corresponding to the seed $\mu_k(\Sigma)$ for some $k \in I$. Then we have

$$e_{a,j}^{(i)} = \begin{cases} 
-e_{a,j}^{(i)} & \text{if } i = k; \\
\sum_{j=1}^{r_i} \left( -c_{a,j}^{(k)} \right) \beta_{ki} & \text{if } i \neq k \text{ and } \beta_{ik} > 0; \\
e_{a,j}^{(i)} + \sum_{j=1}^{r_i} \left( c_{a,j}^{(k)} \right) \beta_{ki} & \text{if } i \neq k \text{ and } \beta_{ik} \leq 0. 
\end{cases}$$

Proof. In the tropical semifield $\text{Trop}(s_a \mid a \in I')$, we have the following expressions:

$$p_{i,j}^{+} = \prod_{a \in I'} s_a \left[ e_{a,j}^{(i)} \right]_{+}, \quad \text{and} \quad p_{i,j}^{-} = \prod_{a \in I'} s_a \left[ -e_{a,j}^{(i)} \right]_{+}.$$ 

Then the result follows by spelling out the mutation formula of coefficients ((3) of Definition 3.2). \square

The matrices and their dynamics in Proposition 3.12 have led to a remarkable combinatorial phenomenon in cluster theory known as the sign coherence of c-vectors. We shall explain it below.

Definition 3.13. We say a generalized cluster algebra $\mathcal{A}$ has principal coefficients at a vertex $t_0 \in T_n$ if $\mathbb{P}$ is the tropical semifield

$$\text{Trop}(p) := \text{Trop}(p_{i,j} \mid i \in I, j \in [1, r_i]),$$

and the seed $\Sigma_{t_0}$ has coefficients $p_i = (p_{i,1}, \ldots, p_{i,r_i})$. In this case, the cluster algebra, denoted as $\mathcal{A}^{\text{prin}}(\Sigma_{t_0})$, is by definition a subalgebra of

$$\mathbb{Z}[x_{i,j}^{\pm}, p_{i,j}^{\pm} \mid i \in I, j \in [1, r_i]].$$

In the case of principal coefficients, the columns of the matrices $C_{\Sigma}^{(i)}$ are called generalized c-vectors. At the initial seed $\Sigma = \Sigma_{t_0}$ with principal coefficients, each $C_{\Sigma}^{(i)}$ is an identity matrix $I_{r_i}$, extended (vertically) by zeros.

Theorem 3.14 (Sign coherence of generalized c-vectors). In the principal coefficients case, for any $t \in T_n$, for any $i \in I$ and any $j \in [1, r_i]$, the entries of the $j$-th column of $C_{\Sigma}^{(i)}$ are either all non-negative or all non-positive.

When $r_i = 1$ for each $i \in I$, i.e. in the case of ordinary cluster algebras, each $C^{(i)} = C_{\Sigma}^{(i)}$ is just a column vector with $n$ entries, altogether forming a matrix $C = (C^{(1)}, \ldots, C^{(n)})$. They are the so-called $C$-matrices in [FZ07] whose columns are c-vectors. In this case, Theorem 3.14 then says that each column of any $C$ is either non-negative or non-positive. This is well-known in the theory of cluster algebras as the sign coherence of c-vectors, which has already been proved by Derksen, Weyman and Zelevinsky [DWZ10] for skew-symmetric exchange matrices and by Gross, Hacking, Keel and Kontsevich [GHKK18] for skew-symmetrizable ones. We will see in Proposition 3.17 that Theorem 3.14 follows from the already established sign coherence of c-vectors.
We set the index set

\[ I' = \bigcup_{i \in I} I'_i, \quad I'_i := \{ (i,j) \mid j \in [1,r_i] \}. \]

**Lemma 3.15.** Let \( \Sigma = \Sigma_{t_0} \) be a seed with principal coefficients. We have the following properties for the matrices \( C^{(i)}_{\Sigma_t} \) for any seed \( \Sigma_t, t \in \mathbb{T}_n \).

1. Let \( i, k \in I \) such that \( k \neq i \). Then for any \( a, a' \in I'_k \) and any \( 1 \leq j, j' \leq r_i \), we have

\[ c^{(i)}_{a,j} = c^{(i)}_{a',j'} \]

2. Let \( i \in I \). We have

\[ c^{(i)}_{(i,1),1} = c^{(i)}_{(i,2),2} = \cdots = c^{(i)}_{(i,r_i),r_i} = c + 1 \]

and

\[ c^{(i)}_{(i,k),j} = c \quad \text{for } k \neq j \]

for some integer \( c \).

**Proof.** We prove this lemma by induction on the distance from \( t \) to \( t_0 \) in \( \mathbb{T}_n \). The base case is for \( c^{(i)}_{\Sigma} \) where the entries in (1) are all zeroes and the ones in (2) are 1 when \( k = j \) and 0 otherwise. Then the properties stated in the lemma are preserved under the mutation formula given in Proposition 3.12. \( \square \)

Let \( \mathbb{T} \) be the tropical semifield \( \text{Trop}(\bar{p}_i \mid i \in I) \). There is a group homomorphism

\[ \pi : \mathbb{T} \to \mathbb{T}, \quad p_{i,j} \mapsto \bar{p}_i. \]

For \( t \in \mathbb{T}_n \), denote the image of \( p_{i,j,t} \) in \( \mathbb{T} \) by \( \bar{p}_{i,t} \) (which is independent of \( j \) by Lemma 3.15) and the image of \( \prod_{j=1}^{r_i} p_{i,j,t} \) in \( \mathbb{T} \) by \( p^t_{i,t} \).

**Lemma 3.16.** The elements \( p_{i,t} \) behave in the following way under the mutation \( \mu_k \). If \( t' \xrightarrow{k} t \) and we write \( p'_i = p_{i,t'} \) and \( p_i = p_{i,t} \), then we have

\[ p'_i = \begin{cases} p_i^{-1} & \text{if } i = k; \\ p_i \cdot (p_k)^{b_{ki}} & \text{if } i \neq k \text{ and } \beta_{ik} > 0; \\ p_i \cdot (p_k')^{b_{ki}} & \text{if } i \neq k \text{ and } \beta_{ik} \leq 0. \end{cases} \]

So they behave under mutations in the same way as \( p_{i,1,t} \) in the case where \( r_i = 1, i \in I \), i.e. the case of ordinary cluster algebras.

**Proof.** By the generalized mutation formula of coefficients, we have

\[ \prod_{j=1}^{r_k} p'_{k,j} = \begin{cases} \prod_{j=1}^{r_k} p_{k,j}^{-1} & \text{if } i = k; \\ \prod_{j=1}^{r_k} p_{k,j} \cdot \left( \prod_{j=1}^{r_k} p_{k,j}^{b_{ki}} \right) & \text{if } i \neq k \text{ and } \beta_{ik} > 0; \\ \prod_{j=1}^{r_k} p_{k,j} \cdot \left( \prod_{j=1}^{r_k} p_{k,j}^{b_{ki}} \right) & \text{if } i \neq k \text{ and } \beta_{ik} \leq 0. \end{cases} \]

By the matrix description of the elements \( p_{k,j} \) in Lemma 3.15, we have that

\[ \prod_{j=1}^{r_k} p_{k,j}^{b_{ki}} = \left( \prod_{j=1}^{r_k} p_{k,j} \right)^{\pm b_{ki}} \in \mathbb{T}, \quad \pi \left( \prod_{j=1}^{r_k} p_{k,j} \right) = p_k^\pm \in \mathbb{T}. \]

The result then follows. \( \square \)

**Proposition 3.17.** The sign coherence of \( c \)-vectors implies the sign coherence of generalized \( c \)-vectors.
Proof. In the case where all $r_i = 1$, the sign coherence then says each column of the matrix $C = (C^{(1)}, \ldots, C^{(n)})$ is either non-negative or non-positive.

On the other hand, by Lemma 3.16, the elements $p_i$ behave under mutations in the exact same way as the coefficients in seeds when all $r_i = 1$ (thus we only have one $p_i$ for each $i$). Thus the column $C^{(i)}$ of $\Sigma$ serves as the coordinates of $p_{i,t}$ in terms of the initial coefficients $p_i$. Then the sign coherence tells that one of $p_{t,j}^+$ and $p_{t,j}^-$ is 1. It then follows from Lemma 3.15 that the corresponding $p_{t,j}^+$ or $p_{t,j}^-$ for each $j \in [1, r_i]$ is also 1, hence the generalized sign coherence. □

The following lemma will be useful later.

**Lemma 3.18.** In the principal coefficient case, for any $t \in \mathbb{T}_n$, the set of coefficients in seed $\Sigma_t$

$$\{p_{i,j,t} \mid i \in I, j \in [1, r_i]\}$$

form a $\mathbb{Z}$-basis of $\mathbb{P} \cong \mathbb{Z}^d$ where $d = \sum_{i \in I} r_i$.

**Proof.** It follows directly from the mutation formula Proposition 3.12 and Lemma 3.15. □

### 3.4. Separation formula

In this section, we describe the separation formula for generalized cluster variables, which can be derived in the exact same way as [FZ07, Theorem 3.7], so we omit the proof.

**Definition 3.19.** Let $\mathcal{A}^{\text{prin}}(\Sigma_{t_0})$ be a generalized cluster algebra with principal coefficients at $\Sigma_{t_0} = (x, p, B)$. We define the rational function

$$X_{l,t} \in \mathbb{Q}_{\text{sf}}(x, p)$$

corresponding to the subtraction-free rational expression of the cluster variable $x_{l,t}$ by iterating exchange relations. Here $(x, p)$ denote the set of all variables in $x$ and $p$.

Define the rational function

$$F_{l,t}(p) = X_{l,t}((1, \ldots, 1), p) \in \mathbb{Q}_{\text{sf}}(p).$$

In general, for a subtraction free expression $F$ in $\mathbb{Q}_{\text{sf}}(x_1, \ldots, x_n)$ and an arbitrary semifield $\mathbb{P}$, we use the notation

$$F \mid_\mathbb{P} (y_1, \ldots, y_n) \in \mathbb{P}$$

for the evaluation at $x_i = y_i$. This evaluation is well-defined (i.e. independent of the expression used) because of the universal property of the semifield $\mathbb{Q}_{\text{sf}}(x_1, \ldots, x_n)$; see Section 2.1.

**Theorem 3.20** (cf. [FZ07, Proposition 3.6, Theorem 3.7]).

1. We have

$$X_{l,t} \in \mathbb{Z}[x_i^\pm; p_{i,j} \mid i \in I, j \in [1, r_i]], \quad F_{l,t} \in \mathbb{Z}[p_{i,j} \mid i \in I, j \in [1, r_i]].$$

2. Let $\mathcal{A}$ be a generalized cluster algebra over an arbitrary semifield $\mathbb{P}'$, with an initial seed $\Sigma_{t_0} = (x, p, B)$. Then the cluster variables in $\mathcal{A}$ can be expressed in the initial cluster as

$$x_{l,t} = \frac{X_{l,t} \mid_\mathbb{P} (x, p)}{F_{l,t} \mid_{\mathbb{P}'} (p)}$$

where $\mathcal{F}$ is the ambient field for $\mathcal{A}$.

**Remark 3.21.** Suppose the positivity for $x_{l,t}$ in the principal coefficients case (where we denote the semifield by $\mathbb{P}$) has been established. This means $X_{l,t}$ has a subtraction free expression as a Laurent polynomial (i.e. whose coefficients are in $\mathbb{N}\mathbb{P}$). Then the evaluation $X_{l,t} \mid_\mathbb{P} (x, p)$ also has positive coefficients in $\mathbb{N}\mathbb{P}'$, while $F_{l,t} \mid_{\mathbb{P}'} (p)$ is an element in $\mathbb{P}'$. Thus it follows by Theorem 3.20 that $x_{l,t}$ has positive coefficients in the case of arbitrary $\mathbb{P}'$.  

14
3.5. Cluster algebras with specialized coefficients. We fix a field \(k\) of characteristic 0 and consider the case of geometric coefficients. In this case, the generalized cluster algebra \(A(\Sigma)\) for \(\Sigma = (x, p, B)\) can be viewed as a subring of \(kP[x^\pm_1, \ldots, x^\pm_n]\) where \(kP\) is the group algebra of \(P\) over \(k\).

Let \(\lambda: P \to k^*\) be a group homomorphism (which we will later refer to as an evaluation). It extends to a \(k\)-algebra homomorphism
\[
\lambda: kP[x^\pm_1, \ldots, x^\pm_n] \to k[x^\pm_1, \ldots, x^\pm_n].
\]
We denote the image of \(A(\Sigma) \otimes_k A(\Sigma, \lambda)\). So we have a family of \(k\)-algebras parametrized by \((k^*)^l\) if the free abelian group \(P\) is of rank \(l\). Each \(A(\Sigma, \lambda)\) is in fact the \(k\)-subalgebra generated by cluster variables (with coefficients specialized by \(\lambda\)) within \(k[x^\pm_1, \ldots, x^\pm_n]\). These are what we call (generalized) cluster algebras with specialized coefficients.

We point out that an ordinary cluster algebra with trivial coefficients (i.e. when \(P\) is trivial) is actually a generalized cluster algebra with specialized coefficients. Suppose \(B\) is a skew-symmetric matrix and let \(r_i\) be the gcd of the \(i\)-th column (if that column is non-zero). Let \(A^{\rm prin}(\Sigma)\) be the generalized cluster algebra with principal coefficients where \(\Sigma\) has exchange matrix \(B\). Choose a group homomorphism \(\lambda: \text{Trop}(p) \to k^*\) such that the specialized exchange polynomials equals the usual cluster exchange binomial, i.e.
\[
\prod_{j=1}^{r_i} (\lambda(p_{i,j})u + v) = u^{r_i} + v^{r_i}.
\]
Of course such \(\lambda\) always exists assuming \(k\) is algebraically closed. Then it is easy to check that every generalized mutation becomes an ordinary mutation: if \(t \longrightarrow t'\),
\[
x_{k,t'} = x_{k,t}^{-1} \left( \prod_{l \in I} x_l^{[b'_{l,k}]} + \prod_{l \in I} x_l^{[-b'_{l,k}]} \right).
\]
Thus the algebra \(A^{\rm prin}(\Sigma, \lambda)\) has the exact same cluster variables as the ordinary cluster algebra with trivial coefficients, and can thus be viewed as an ordinary cluster algebra.

3.6. An example in type \(B_2\) with principal coefficients. We consider \(A^{\rm prin}(x, p, B)\) with principal coefficients for \(B = \begin{bmatrix} 0 & -2 \\ 1 & 0 \end{bmatrix}\) which is of type \(B_2\) in the finite type classification [FZ03] and [CS14, Theorem 2.7]. We write \(x_{1,2} = A_1\), and \(p_{1,2,t} = t_{ij}\). For the subgraph
\[
t_0 \longrightarrow t_1 \longrightarrow t_2 \longrightarrow t_3 \longrightarrow t_4 \longrightarrow t_5 \longrightarrow t_6
\]
of \(T_2\), we have the associated labeled seeds calculated in Table 1.

We note that the \(\Sigma_{t_0}\) is not exactly the same as the \(\Sigma_{t_0}\) but up to a switch of \(p_{2,1}\) and \(p_{2,2}\).

3.7. Generalized Y-seeds. We define generalized Y-seeds (with coefficients) and their mutations. The formulation to including coefficients in Y-seeds comes from [BFMMN20]. The following definition is a generalization of [BFMMN20, Definition 2.15], which is an enhancement of a Y-seed of [FZ07].

**Definition 3.22.** A generalized labeled Y-seed (with coefficients) \(\Delta\) is a triple \((y, q, B)\), where

- \(q = (q_1, \ldots, q_n)\) is an \(n\)-tuple of \(r_i\)-tuples \(q_i = (q_{i,1}, \ldots, q_{i,r_i})\) of elements in a semifield \(P\) for positive integers \(r_i, 1 \leq i \leq n\).
- \(y = (y_1, \ldots, y_n)\) is a collection of elements in some universal semifield \(Q P_{sf}(u_1, \ldots, u_l)\).
- \(B\) is a left skew-symmetric integer matrix such that the \(i\)-th column is divisible by \(r_i\) for every \(i\).
\[
\begin{array}{|c|c|c|c|c|c|}
\hline
 t & B' & \text{p}_{1,t} & \text{p}_{2,t} & x_{1,t} & x_{2,t} \\
\hline
0 & \begin{bmatrix} 0 & -2 \\ 1 & 0 \end{bmatrix} & t_{11} & t_{21} & t_{22} & A_1 \\
\hline
1 & \begin{bmatrix} 0 & 2 \\ -1 & 0 \end{bmatrix} & t_{11}^{-1} & t_{21} & t_{22} & A_1^{-1}(1 + t_{11}A_2) \\
\hline
2 & \begin{bmatrix} 0 & -2 \\ 1 & 0 \end{bmatrix} & t_{11}^{-1} & t_{21}^{-1} & t_{22}^{-1} & A_1^{-1}(1 + t_{11}A_2) \\
\hline
3 & \begin{bmatrix} 0 & 2 \\ -1 & 0 \end{bmatrix} & t_{11}^{-1}t_{21}^{-1}t_{22}^{-1} & t_{11}t_{21} & t_{11}t_{22} & A_1^{-1}(1 + t_{11}A_2) \\
\hline
4 & \begin{bmatrix} 0 & -2 \\ 1 & 0 \end{bmatrix} & t_{11}t_{21}t_{22} & t_{21}^{-1} & t_{22}^{-1} & A_1 \\
\hline
5 & \begin{bmatrix} 0 & 2 \\ -1 & 0 \end{bmatrix} & t_{11}t_{21}t_{22} & t_{22}^{-1} & t_{21}^{-1} & A_1 \\
\hline
6 & \begin{bmatrix} 0 & -2 \\ 1 & 0 \end{bmatrix} & t_{11} & t_{22} & t_{21} & A_1 \\
\hline
\end{array}
\]

Table 1. Labeled seeds of $\mathcal{A}^{\text{prin}}$

**Definition 3.23.** For $k \in \{1, \ldots, n\}$, we define the mutation of a $Y$-seed $(y, q, B)$ in direction $k$ as a new $Y$-seed $\mu_k(y, q, B) := ((y'_i), (q'_j), B')$ in the following way:

\[(3.1) \quad B' = \mu_k(B); \]

\[
q'_{k,j} = q_{k,j}^{-1} \quad \text{for } j \in [1, r_k];
\]

\[
(3.2) \quad q'_{i,j} = \begin{cases} 
q_{i,j} \cdot \left( \prod_{l=1}^{r_k} q_{k,l}^{-} \right)^{-\beta_{ik}} & \text{if } -\beta_{ki} > 0 \\
q_{i,j} \cdot \left( \prod_{l=1}^{r_k} q_{k,l}^{+} \right)^{-\beta_{ik}} & \text{if } -\beta_{ki} \leq 0,
\end{cases}
\]

or equivalently

\[
(3.3) \quad y'_i = \begin{cases} 
y_i \prod_{l=1}^{r_k} \left( q_{k,l}^{-} \frac{\text{sgn}(\beta_{ik})}{y_{k,l}} + q_{k,l}^{+} \frac{\text{sgn}(\beta_{ik})}{y_{k,l}} \right)^{\beta_{ik}} & \text{if } i \neq k \\
y_i^{-1} & \text{if } i = k.
\end{cases}
\]

As in Lemma 3.3, it is straightforward to check that the mutation $\mu_k$ on a generalized $Y$-seed is involutive in the same direction.
**Definition 3.24.** A generalized $Y$-pattern is an association
\[ t \mapsto \Delta_t = (y_t, q_{i, t}, B^t) \]
to every vertex $t \in T_n$ a generalized labeled $Y$-seed $\Delta_t$ such that if $t$ and $t'$ are connected by an edge labeled by $k \in I$, then we have
\[ \Delta_{t'} = \mu_k(\Delta_t). \]

**Definition 3.25.** We say that a generalized $Y$-pattern has principal coefficients at a vertex $t_0 \in T_n$ if $\mathbb{P}$ is the tropical semifield
\[ \text{Trop}(q_{i,j,t_0} \mid i \in I, j \in [1, r_i]). \]

Given a $Y$-pattern, the elements $y_{i,t}$ for $t \in T_n$ are called $Y$-variables.

**Remark 3.26.** In the case that for any $i$, $q_{i,1} = q_{i,2} = \cdots = q_{i,r_i},$
a generalized $Y$-seed with coefficients as in Definition 3.22 becomes a labeled $Y$-seed with coefficients in $[\text{BFMMNC20}]$. In this case, the mutation formula of $Y$-variables is independent of the choice $r_i$. So we get back to the non-generalized version by letting the coefficients $q_{i,j}, j \in [1, r_i]$, equal. While in the cluster case, one recovers the non-generalized seed mutation by choosing $r_i = 1$. This asymmetry suggests that our generalization is a natural one.

To the best knowledge of the author, the generalized version of $Y$-patterns has not been considered in the literature. It is interesting to see if these generalized patterns appear naturally anywhere.

## 4. Generalized cluster varieties

Cluster varieties were introduced by Fock and Goncharov [FG09], giving a geometric view to cluster algebras (of geometric types). We follow [GHK15] to define relevant notions such as fixed data and seeds. However, in order to deal with generalized coefficients, some new gadgets are needed.

**Definition 4.1.** We recall the fixed data $\Gamma$ from [GHK15]. The fixed data $\Gamma$ consists of
- a lattice $N$ of finite rank with a skew-symmetric bilinear form $\omega: N \times N \to \mathbb{Q}$;
- an unfrozen sublattice $N_{af} \subset N$, a saturated sublattice of $N$;
- an index set $I = \{1, \ldots, \text{rank } N\}$ and a subset $I_{af} = \{1, \ldots, \text{rank } N_{af}\}$;
- positive integers $d_i$ for $i \in I$ with greatest common divisor 1;
- a sublattice $N^o \subset N$ of finite index such that $\omega(N_{af}, N^o) \subset \mathbb{Z}$, $\omega(N, N_{af} \cap N^o) \subset \mathbb{Z}$;
- $M = \text{Hom}(N, \mathbb{Z})$, $M^o = \text{Hom}(N^o, \mathbb{Z})$.

### 4.1. Generalized $A$-cluster variety.

**Definition 4.2.** Given fixed data $\Gamma$, an $A$-seed with (generalized) coefficients is a pair $s = (e, p)$ consisting of a seed $e = (e_i)_{i \in I}$ which is a labeled collection of elements in $N$ and a labeled collection of tuples of coefficients $p = (p_i)_{i \in I_{af}}$ where $p_i = (p_{i,j})_{j \in [1, r_i]}$ and $p_{i,j}$ belongs to some tropical semifield $\mathbb{P}$ such that

1. $\{e_i \mid i \in I\}$ is a basis for $N$;
2. $\{e_i \mid i \in I_{af}\}$ is a basis for $N_{af}$;
3. $\{d_i e_i \mid i \in I\}$ is a basis for $N^o$;
4. for $i \in I_{af}$, the elements $w_i := \omega(-, d_i e_i)/r_i$ belong to $M$.

For such a seed $s$, we define two matrices $B = B(s) = (b_{ij})$ and $\tilde{B} = \tilde{B}(s) = (\beta_{ij})$ by setting
\[ b_{ij} := \omega(e_i, d_j e_j) \quad \text{and} \quad \beta_{ij} := \langle e_i, w_j \rangle = b_{ij}/r_j. \]
Definition 4.3. Given $s$ an $A$-seed with coefficients, for $k \in I_{uf}$, we define the mutation in direction $k$, $\mu_k(s) = (e', p')$ by
\[
e'_i = \begin{cases} 
-e_k & \text{if } i = k \\
e_i + [(e_i, -r_k w_k)]_+ e_k & \text{if } i \neq k;
\end{cases}
\]
and
\[
p'_{k,j} = p_{k,j}^{-1} \quad \text{for } j \in [1, r_k];
\]
\[
p'_{i,j} = \begin{cases} 
p_{i,j} \cdot (p_{k,-})^{\beta_{ki}} & \text{if } \beta_{ki} > 0 \\
p_{i,j} \cdot (p_{k,+})^{\beta_{ki}} & \text{if } \beta_{ki} \leq 0,
\end{cases}
\]

Remark 4.4. If we write $w'_i = \omega(-\frac{d_i}{e_i} e'_i)$ as the mutations of $w_i$, then they are given by
\[
w'_i = \begin{cases} 
-w_k, & \text{if } i = k; \\
w_i + [(r_k e_k, w_i)]_+ w_k, & \text{if } i \neq k.
\end{cases}
\]
Denote the dual basis of $(e_i)$ by $(e^*_i)$ and the dual of $(e'_i) = \mu_k(e)$ by $(e'^*_i)$. We have
\[
e^{',*}_i = \begin{cases} 
e^*_k + \sum_j [(e_j, -r_k w_k)]_+ e^*_j & \text{if } i = k; \\
e^*_i & \text{if } i \neq k.
\end{cases}
\]
If there is no confusion, we will call an $A$-seed with coefficients simply a seed.

Let $R = k\mathbb{P}$, the group algebra of $P$ over the ground field $k$. To any $A$-seed $s$, we associate a copy of the $R$-torus $T_{N,s}(R) \coloneqq \text{Spec}(k[M] \otimes_k R)$.

Definition 4.5. To the mutation $\mu_k$ from $s$ to $\mu_k(s)$, there is an associated birational morphism (over $R$)
\[
\mu_k : T_{N,s}(R) \longrightarrow T_{N,\mu_k(s)}(R), \quad \mu_k^*(z^m) = z^m f_k^{-1}(e_k - m),
\]
where
\[
f_k := \prod_{j=1}^{r_k} \left(p_{k,j}^- + p_{k,j}^+ z^{w_k} \right) \in R[M].
\]
We call this birational transformation the $A$-cluster mutation associated to the mutation $\mu_k$ of seeds.

Definition 4.6. We define the oriented rooted tree $\Sigma_n$ (where $n = |I_{uf}|$) as in [GHK15]. It is the infinite tree generated from a root $v_0$ such that

1. $v_0$ has outgoing edges labeled by $I_{uf} = \{1, \ldots, n\}$;
2. any other vertex has one unique incoming edge, and outgoing edges labeled by $I_{uf}$.

Let $v_0 \in \Sigma_n$ be the root. Then for any other vertex $v \in \Sigma_n$, there is a unique oriented path from $v_0$ to $v$. We associate a seed $s$ to the root $v_0$, the unique path from $v$ to $v_0$ determines a seed $s_v$ by applying the mutations in directions of the labelings in the path to the initial seed $s$. Therefore we have an association $v \mapsto s_v$ for $v \in \Sigma_n \setminus \{v_0\}$ and $v_0 \mapsto s$ such that for an edge $v \xrightarrow{k} v'$ in $\Sigma_n$, then
\[
s_{v'} = \mu_k(s_v).
\]
Suppose the unique path from $v_0$ to $v$ walks through edges labeled by $k_1, k_2, \ldots, k_l$. There is then the birational map
\[
\mu_{v_0,v} := \mu_{k_1} \circ \cdots \circ \mu_{k_l} : T_{N,s}(R) \longrightarrow T_{N,\mu_k(s)}(R).
\]
For arbitrary two vertices $v$ and $v'$ in $\Sigma_n$, there is the birational map
\[
\mu_{v,v'} := \mu_{v_0,v} \circ \mu_{v_0,v'}^{-1} : T_{N,s_v}(R) \longrightarrow T_{N,s_{v'}}(R).
\]
These birational maps surely satisfy the cocycle condition. We use the following lemma to glue $T_{N,s_v}$ together.
Lemma 4.7 ([BFMMNCG20, Lemma 3.10], [GHK15, Proposition 2.4]). Let \( I \) be a set and \( \{ S_i \mid i \in I \} \) be a collection of integral separated schemes of finite type over a locally Noetherian ring \( R \), with birational maps (of \( S \)-schemes) \( f_{ij} : S_i \to S_j \) for all \( i, j \), verifying the cocycle condition \( f_{jk} \circ f_{ij} = f_{ik} \) as rational maps and such that \( f_{ii} \) is the identity map. Let \( U_{ij} \subset S_i \) be the largest open subscheme such that \( f_{ij} : U_{ij} \to f_{ij}(U_{ij}) \) is an isomorphism. Then there is an \( S \)-scheme
\[
S = \bigcup_{i \in I} S_i
\]
obtained by gluing the \( S_i \) along the open sets \( U_{ij} \) via the maps \( f_{ij} \).

Definition 4.8. Let \( \Gamma \) be fixed data and \( s \) be an \( \mathcal{A} \)-seed with coefficients. We apply Lemma 4.7 to glue together the collection of tori indexed by \( \Xi_n \) to get the \emph{generalized \( \mathcal{A} \)-cluster variety} associated to \( s \) (as an \( S \)-scheme)
\[
\mathcal{A}_s = \mathcal{A}_{\Gamma,s} := \bigcup_{v \in \mathcal{T}} T_{N,s_v}(R).
\]

We now explain how to obtain a generalized cluster pattern from \( \mathcal{A}_s \), justifying the name generalized \( \mathcal{A} \)-cluster variety. We assume \( N_{\text{aff}} = N \), thus \( I_{\text{aff}} = I \).

Recall we have the association \( v \mapsto s_v = \mu_{v_0,v}(s) \) for \( v \in \Xi_n \). We write \( s_v = (e_v, p_v) \) where \( e_v = (e_{iv} \mid i \in I) \), \( p_v = (p_{iv} \mid i \in I) \) and \( p_{iv} = (p_{ij,v} \mid j \in [1, r_i]) \).

Sending \( v_0 \) to any vertex \( t_0 \) in the \( n \)-regular tree \( \mathcal{T}_n \) gives a unique surjective map
\[
\pi : \Xi_n \to \mathcal{T}_n, \quad v_0 \mapsto t_0
\]
such that the labeling on edges is preserved.

For any seed \( v \in \Xi_n \), there is the corresponding labeled seed with coefficients (in the sense of Definition 3.1)
\[
\Sigma_v = \Sigma(s_v) := (x_v, p_v, B^v)
\]
where
\[
x_{i,v} := \mu_{v_0,v}^* \left( z_{i,v}^v \right) \in \mathbb{Q}[x_1, \ldots, x_n], \quad b_{ij}^v := \omega(e_{iv}, d_{ij,v}),
\]
where \( x_i = x_{i,v_0} \).

Lemma 4.9. If two vertices \( v \) and \( v' \) vertices of \( \Xi_n \) descend to the same vertex in \( \mathcal{T}_n \), i.e. \( \pi(v) = \pi(v') \), then their corresponding labeled seeds with coefficients are identical, i.e. \( \Sigma_v = \Sigma_v' \).

Proof. Suppose the unique path in \( \Xi_n \) from \( v_0 \) to \( v \) goes through edges labeled by \( k_1, \ldots, k_l \) in order. We show in the following by induction that
\[
\mu_k \circ \cdots \circ \mu_{k_1} (\Sigma_{v_0}) = \Sigma_v,
\]
where the operation \( \mu_k \) is the mutation in direction \( k \) of labeled seeds with coefficients in the sense of Definition 3.2.

Let \( v_1 \xrightarrow{k} v_2 \) be in \( \Xi_n \). Then one checks \( B^{v_2} = \mu_k(B^{v_1}) \) using the fact that \( e_{v_2} = \mu_k(e_{v_1}) \), which is standard from [GHK15]. The coefficients parts \( p_{v_1} \) and \( p_{v_2} \) are related by the mutation \( \mu_k \) by definition. So we only need to check that \( x_{v_1} \) and \( x_{v_2} \) are also related by \( \mu_k \).

Note that \( \mu_{v_0,v_2}^* = \mu_{v_0,v_1}^* \circ \mu_k^* \). So we have for \( i \neq k \)
\[
x_{i,v_2} = \mu_{v_0,v_1}^* \left( \mu_k^* \left( z_{i,v_2}^v \right) \right) = \mu_{v_0,v_1}^* \left( z_{i,v_1}^v \right) = x_{i,v_1}
\]
\[\]
and
\[ x_{k_1\cdots k_l} = \mu_{v_0,v_1}^* \left( \mu_k^* \left( z_{k_1\cdots k_l} \right) \right) \]
\[ = \mu_{v_0,v_1}^* \left( \left( -e_{k_1}, \ldots, e_{k_l} \right) \prod_{j=1}^{r_k} \left( p_{k,j,v_1}^- z_{w_{k,v_1}}^- + p_{k,j,v_1}^+ z_{w_{k,v_1}}^+ \right) \right) \]
\[ = \mu_{v_0,v_1}^* \left( z_{e_{k_1}} \prod_{j=1}^{r_k} \left( p_{k,j,v_1}^- z_{w_{k,v_1}}^- + p_{k,j,v_1}^+ z_{w_{k,v_1}}^+ \right) \right) \]
\[ = \mu_{v_0,v_1}^* \left( z_{e_{k_1}} \prod_{j=1}^{r_k} \left( p_{k,j,v_1}^- \mu_{v_0,v_1}^* \left( z_{w_{k,v_1}}^- \right) + p_{k,j,v_1}^+ \mu_{v_0,v_1}^* \left( z_{w_{k,v_1}}^+ \right) \right) \right) \]
\[ = x_{k_1\cdots k_l}^{-1} \prod_{j=1}^{r_k} \left( p_{k,j,v_1}^- \prod_{i\in I} x_{i,v_1}^{-\beta_i^+} + p_{k,j,v_1}^+ \prod_{i\in I} x_{i,v_1}^{\beta_i^+} \right). \]

The only unexplained notation in the above equations is that for any \( w = \sum_{i\in I} a_i e_i^* \in M \), we write
\[ w^- := \sum_{i\in I} [-a_i]_+ e_i^* \quad \text{and} \quad w^+ := \sum_{i\in I} [a_i]_+ e_i^*. \]

Now we have checked that \( \mu_k(\Sigma_{v_0}) = \Sigma_{v_2} \). By induction on the distance from \( v \) to the root \( v_0 \), we conclude that \( \mu_k \circ \cdots \circ \mu_k(\Sigma_{v_0}) = \Sigma_v \) for any \( v \in \mathcal{T}_n \). Since \( \mu_k \) is involutive, we can reduce the sequence \((k_1, \ldots, k_l)\) by deleting pairs of consecutive identical indices until there is none. So \( \Sigma_v \) only depends on the reduced sequence of edge labels from \( v_0 \) to \( v \). Now notice that two vertices \( v \) and \( v' \) in \( \mathcal{T}_n \) have the same projection \( t \) in \( \mathcal{T}_n \) if and only if they have the same reduced sequence of edge labels from \( v_0 \), meaning the same labeled seed with coefficients \( \Sigma_t := \Sigma_v = \Sigma_{v'} \).

\[ \square \]

**Proposition 4.10.** According to the above lemma, we have that the labeled seeds \( \Sigma_v \) and \( \Sigma_{v'} \) are equal if \( \pi(v) = \pi(v') = t \in \mathcal{T}_n \). So we can denote them all by \( \Sigma_t \). The association \( t \mapsto \Sigma_t \) for every \( t \in \mathcal{T}_n \) is a cluster pattern.

**Proof.** Suppose the unique path from \( t_0 \) to some \( t \in \mathcal{T}_n \) walks through edges in order of \( k_1, \ldots, k_l \). Then already in the proof of the above lemma, we have
\[ \Sigma_t = \mu_{k_l} \circ \cdots \circ \mu_{k_1}(\Sigma_{t_0}). \]

This association by definition gives a cluster pattern. \( \square \)

**Definition 4.11.** The (generalized) upper cluster algebra \( \mathcal{A}(\mathbf{s}) \) (of an \( \mathcal{A} \)-seed \( \mathbf{s} \) with coefficients) is defined to be the \( R \)-algebra
\[ H^0(\mathcal{A}_s, \mathcal{O}_{\mathcal{A}_s}) = \bigcap_{t \in \mathcal{T}_n} H^0 \left( T_{N,s_t}(R), \mathcal{O}_{T_{N,s_t}(R)} \right), \]
the ring of regular functions on the (generalized) \( \mathcal{A} \)-cluster variety \( \mathcal{A}_s \).

By definition the upper cluster algebra is the algebra of all Laurent polynomials that remains Laurent polynomials after an arbitrary sequence of mutations. It follows from the Laurent phenomenon that all cluster variables are elements in the upper cluster algebra, thus the inclusion
\[ \mathcal{A}(\mathbf{s}) \subset \mathcal{A}(\mathbf{s}), \]
where the former denotes the subalgebra generated by cluster variables, i.e. the cluster algebra (over \( R \)).

The notion of principal coefficients can be easily translated into the current setting.
Definition 4.12. An \( \mathcal{A} \)-seed \( s \) is said to have principal coefficients if the associated labeled seed \( \Sigma(s) \) has principal coefficients.

The associated cluster pattern with \( t_0 \mapsto \Sigma(s) \), \( t \mapsto \Sigma(s_v) \) (where \( t = \pi(v) \)) then has principal coefficients at \( t_0 \). In this case, we denote the corresponding cluster variety by \( \mathcal{A}_s^{\text{prin}} \).

4.2. Generalized \( \mathcal{X} \)-cluster variety. Given fixed data \( \Gamma \) as in the last section, we define the notion of (generalized) \( \mathcal{X} \)-seeds with coefficients.

Definition 4.13. An \( \mathcal{X} \)-seed with (generalized) coefficients \( s = (e, q) \) is the same as an \( \mathcal{A} \)-seed. We use the symbol \( q \) instead of \( p \) to stress that it is an \( \mathcal{X} \)-seed.

What distinguish \( \mathcal{X} \)-seeds with \( \mathcal{A} \)-seeds is the mutation.

Definition 4.14. Given an \( \mathcal{X} \)-seed \( s = (e, q) \), we define the mutation in direction \( k \), \( \mu_k(s) = (e', q') \) by

\[
e'_i = \begin{cases} -e_k & \text{if } i = k \\ e_i + [(e_i, -r_k w_k)]_+ e_k & \text{if } i \neq k; \end{cases}
\]

and

\[
q'_{k,j} = q^{-1}_{k,j} \quad \text{for } j \in [1, r_k];
\]

\[
q'_{i,j} = \begin{cases} q_{i,j} \cdot (q_{k,j}^{-1})_{-\beta_{ik}} & \text{if } -\beta_{ki} > 0 \\ q_{i,j} \cdot (q_{k,j}^{-1})_{-\beta_{ik}} & \text{if } -\beta_{ki} \leq 0, \end{cases}
\]

So the pure seed part \( e \) behaves in the same way under mutation as in an \( \mathcal{A} \)-seed while the coefficients part \( q \) mutates differently, but same as the coefficients in a labeled \( Y \)-seed. Roughly, if in \( \mathcal{A} \)-seeds, the matrix \( B \) governs the mutation of coefficients, then in \( \mathcal{X} \)-seeds, \( -B^T \) does the job.

Definition 4.15. Let \( s = (e, q) \) be an \( \mathcal{X} \)-seed with coefficients. Then there is the associated \( \mathcal{X} \)-cluster mutation

\[
\mu_k : T_M(R) \rightarrow T_M(R), \quad \mu^*_k(z^n) = z^n \left( \prod_{l=1}^{r_k} (q_{k,l}^{-1} + q_{k,l}^{+} z^{e_k}) \right)^{-(n,-w_k)},
\]

where \( T_M(R) \) is the \( R \)-torus \( \text{Spec}(k[N] \otimes R) \).

Definition 4.16. Let \( s \) be an \( \mathcal{X} \)-seed for \( \Gamma \). Then there is a unique association \( v \mapsto s_v \) for every \( v \in \mathcal{T}_n \) such that \( v_0 \mapsto s \) and adjacent associated seeds are related by mutations of \( \mathcal{X} \)-seeds in corresponding directions. Define the generalized \( \mathcal{X} \)-cluster variety associated to \( s \) to be the \( R \)-scheme

\[
\mathcal{X}_s = \mathcal{X}_{\Gamma,s} := \bigcup_{v \in \mathcal{T}_n} T_{M,s_v}(R)
\]

obtained by gluing \( T_{M,s_v}(R) \) via \( \mathcal{X} \)-cluster mutations using Lemma 4.7.

Write \( s_v = ((e_i, v), (q_{i,v})) \). Let us keep track of the monomials \( z^{e_i, v} \in k[N] \) (instead of \( z^{\epsilon_i, v} \) in the \( \mathcal{A} \)-case). We define

\[
y_{i,v} := \mu^*_v(v_0)(z^{e_i, v}) \in \text{Frac}(k[N] \otimes R).
\]

It turns out that these \( y_{i,v} \) are the \( Y \)-variables of the \( Y \)-pattern induced by the \( \mathcal{X} \)-seed \( s \) described as follows. We take \( s \) as the initial seed. Analogous to the \( \mathcal{A} \)-situation, any vertex \( v \in \mathcal{T}_n \) descends to a vertex \( t = \pi(v) \in \mathcal{T}_n \).

Proposition 4.17. For \( v \in \mathcal{T}_n \), define the generalized labeled \( Y \)-seed \( \Delta_v = ((y_{i,v}), (q_{i,v}), B^v) \). Then we have \( \Delta_v = \Delta_{v'} \) if \( \pi(v) = \pi(v') = t \in \mathcal{T}_n \). Then the association \( t \mapsto \Delta_t \) for \( t \in \mathcal{T}_n \) is a generalized \( Y \)-pattern with coefficients where \( \Delta_t := \Delta_v \) for any \( v \) such that \( t = \pi(v) \).
Proof. We first note that the $Y$-variables $y_{i,v}$ live in the universal semifield $\mathbb{QP}_{sf}(y_1, \ldots, y_n)$ where $y_i = z^{e_i}$ are the initial $Y$-variables. The proof is completely analogous to proposition 4.10. We leave the details to the reader. □

4.3. Special coefficients. By construction, given an $A$-seed (resp. $X$-seed) $s$, there is the flat family

$$\pi_A: A_s \to \text{Spec } R \quad (\text{resp. } \pi_X: X_s \to \text{Spec } R).$$

Let $\lambda$ be a $k$-point of Spec $R$. Then the special fiber $\pi^{-1}(\lambda)$ is a $k$-scheme and can be viewed as a generalized cluster variety with special coefficients, denoted by $A_{s,\lambda}$ (resp. $X_{s,\lambda}$). They are also glued together by tori via birational morphisms (namely the $A$- or $X$-mutations specialized at $\lambda$)

$$A_{s,\lambda} = \bigcup_{v \in T_n} T_{N,v}, \quad X_{s,\lambda} = \bigcup_{v \in T_n} T_{M,v}.$$ 

The $A$-type varieties (resp. $X$-type varieties) lead to cluster patterns (resp. $Y$-patterns) with specialized coefficients. We have as before in the $A$-case the inclusion of algebras

$$\mathcal{A}(s, \lambda) \subset \mathcal{A}(s, \lambda) := H^0(A_{s,\lambda}, \mathcal{O}_{A_{s,\lambda}}).$$

4.4. Cluster duality. The cluster duality of Fock and Goncharov predicts, in the ordinary case, that the varieties $A_s$ and $X_s$ are dual in the sense that the upper cluster algebra $\mathcal{A}(s)$ has a basis parametrized by the tropical set $X^{\text{trop}}(\mathbb{Z})$ (and vice versa). Note here $s$ is viewed as a seed without coefficients so we do not need to distinguish between $A$- and $X$-seeds. Strictly speaking, this statement is not true as in some cases $X_s$ may have too few regular functions [GHK15]. This duality (or named the Fock–Goncharov full conjecture) is the main subject of study (on a precise modified formulation and when it is true) in the paper [GHKK18].

Our point of view is that it is more natural to include generalized cluster varieties in cluster dualities, which we will demonstrate in the principal coefficients case. We denote the $X$-cluster variety with principal coefficients by $X^{\text{prin}}_s$, where the coefficient group is the tropical semifield $\mathbb{P} = \text{Trop}([q_{ij} \mid i \in I, j \in [1, r_i]])$.

The scheme $X^{\text{prin}}_s$ is over Spec$(R)$ where $R = k\mathbb{P}$. There are evaluations $\lambda$ sending $q_{ij}$ to $\lambda_{ij} \in k^*$. Each $\lambda$ specifies an $X$-cluster variety with special coefficients as in the following diagram

$$
\begin{array}{c}
\pi^{\text{prin}}_{s,\lambda} & \longrightarrow & X^{\text{prin}}_s \\
\downarrow & & \downarrow_{\pi_X} \\
\text{Spec}(k) & \overset{\lambda}{\longleftarrow} & \text{Spec}(R).
\end{array}
$$

With a general choice coefficients, $X^{\text{prin}}_{s,\lambda}$ should be considered mirror dual to the family

$$\pi_A: A^{\text{prin}}_s \to \text{Spec } R,$$

where $s$ is viewed as an $A$-seed with coefficients. We shall not fully justify this statement in this paper, but instead will show that the family $\pi_A: A^{\text{prin}}_s \to \text{Spec } R$ (as well as the generalized cluster algebra $\mathcal{A}_s^{\text{prin}}(s)$) can be reconstructed from $A^{\text{prin}}_{s,\lambda}$ through a consistent wall-crossing structure (or scattering diagram) $\mathcal{D}_s$ associated to $A^{\text{prin}}_{s,\lambda}$; see Section 8.
5. Toric models and mutations

This section is a generalization of [GHK15, Section 3] aiming for generalized cluster varieties. A log Calabi–Yau pair \((X, D)\) is a smooth projective variety \(X\) (over an algebraically closed field \(k\)) with a reduced simple normal crossing divisor \(D\) such that \(K_X + D = 0\) where \(K_X\) is the canonical divisor of \(X\). A log Calabi–Yau variety \(U\) is the interior of a log Calabi–Yau pair \((X, D)\), i.e. \(U = X \setminus D\). Described in [GHK15], particularly relevant in cluster theory are log Calabi–Yau pairs \((X, D)\) obtained from a blow-up \(\pi: X \to X_{\Sigma}\) where \(X_{\Sigma}\) is the toric variety associated to a fan \(\Sigma\) in \(\mathbb{R}^n\). The blow-up is along a hypersurface in the toric boundary of \(X_{\Sigma}\), and \(D\) is given by the strict transform of the toric boundary. We will see that both generalized \(X\)- and \(A\)-varieties can be realized as log Calabi–Yau varieties obtained this way (up to codimension two subsets).

5.1. Toric models. Fix a lattice \(N \cong \mathbb{Z}^n\) and let \(M\) be its dual. Suppose for \(i \in I = [1, l]\) we have pairs of vectors \((e_i, w_i) \in N \times M\) such that \(\langle e_i, w_i \rangle = 0\). We assume that all non-zero \(e_i\) are primitive, but some of them may equal. For each \(i\), we fix a positive integer \(r_i\). We also take functions (elements in \(k[M]\))

\[
f_i = a_{i,0} + a_{i,1} z^{w_i} + \cdots + a_{i,r_i} z^{r_i w_i}
\]

with non-zero \(a_{i,0}\) and \(a_{i,r_i}\).

We construct in below a log Calabi–Yau variety \(U_\Lambda\) using the data

\[
\Lambda := ((e_i)_{i \in I}, (w_i)_{i \in I}, (f_i)_{i \in I})
\]

The following construction is what we mean by a toric model for \(U_\Lambda\) and we call such \(\Lambda\) a toric model data.

Construction 5.1 (cf. [GHK15, Construction 3.4]). Given the data \(\Lambda\), consider the fan

\[
\Sigma = \Sigma_\Lambda := \{\mathbb{R}_{\geq 0} e_i \mid i \in I\} \cup \{0\}
\]

in \(N_\mathbb{R}\). Let \(X_{\Sigma}\) be the toric variety defined by \(\Sigma\), and \(D_i\) be the irreducible toric boundary divisor corresponding to \(\mathbb{R}_{\geq 0} e_i\). Note that since \(\langle e_i, w_i \rangle = 0\), \(z^{w_i}\) does not vanish on \(D_i\). Let \(Z_i\) be the zero locus of \(f_i\) on \(D_i\), i.e. the closed subscheme \(V(f_i) \cap D_i\), which is a hypersurface. Blow up \(X_{\Sigma}\) along \(\bigcup_{i=1}^l Z_i\) to obtain

\[
\pi: \tilde{X}_{\Sigma} \to X_{\Sigma}.
\]

Let \(\tilde{D}_i\) be the strict transform of \(D_i\) in \(\tilde{X}_{\Sigma}\). Then the open subscheme \(U_\Lambda := \tilde{X}_{\Sigma} \setminus \bigcup_i \tilde{D}_i\) is a log Calabi–Yau variety.

Definition 5.2. For \(k \in I\), we say a toric model data \(\Lambda\) \(k\)-mutable if the pairs \((e_i, w_i)\) satisfy the condition

\[
\langle e_i, w_k \rangle = 0 \implies \langle e_k, w_i \rangle = 0
\]

for any \(i \in I\).

We define mutations of a \(k\)-mutable toric model data.

Definition 5.3. Let \(\Lambda\) be a \(k\)-mutable toric model data and \(\Lambda' = ((e'_i), (w'_i), (f'_i))\) be another set of data. Write \(\beta_{ij} = \langle e_i, w_j \rangle\). We write \(\Lambda' = \mu_k(\Lambda)\) (or say they are \(\mu_k\)-equivalent) if they satisfy the following conditions:

- \(e'_k = -e_k\) and \(w'_k = -w_k\);
- if \(i \neq k\) and \(\beta_{ik} \geq 0\), \(e_i = e_i\) and \(w'_i = w_i\);
- if \(i \neq k\) and \(\beta_{ik} \leq 0\), \(e'_i = e_i - \langle e_i, r_k w_k \rangle e_k\) and \(w'_i = w_i + \langle e_k, w_i \rangle r_k w_k\);

and if writing \(f'_i = a'_{i,0} + a'_{i,1} z^{w'_i} + \cdots + a'_{i,r_i} z^{r_i w'_i}\),

\[
a'_{k,j} = a_{k,r_k-j} \quad \text{for } j \in [1, r_k];
\]
for $i \neq k, j \in [1, r_i],$ 

\[(5.1)\]  
\[
a'_{i,j}/a'_{i,0} = \begin{cases} (a_{k,0})^{\beta_{ki}} \cdot a_{i,j}/a_{i,0} & \text{if } \beta_{ki} > 0 \\ (a_{k,0})^{\beta_{ki}} \cdot a_{i,j}/a_{i,0} & \text{if } \beta_{ki} \leq 0. \end{cases} \]

We note that the mutation $\mu_k$ is not deterministic for the $(f_i)$ part, and is not involutive for the $((e_i), (w_i))$ part.

Applying Construction 5.1 to $\Lambda' = \mu_k(\Lambda)$, we obtain another log Calabi–Yau variety $U_{\Lambda'}$. Note that both $U_\Lambda$ and $U_{\Lambda'}$ contain the torus $T_N$. Consider the birational morphism

$\mu_k : T_N \dashrightarrow T_N, \quad \mu_k^*(z^m) = z^m \cdot f_k^{-(m,e_k)}.$

The following theorem is a generalization of the results in [GHK15, Section 3].

**Theorem 5.4.** The birational morphism $\mu_k$ extends to an isomorphism $\mu_k : U_\Lambda \rightarrow U_{\Lambda'}$ outside codimension two subsets if $\dim \tilde{V}(f_k) \cap Z_i < \dim Z_i$ whenever $(e_i, w_k) = 0$ for $i \in I$.

**Proof.** We first make up some auxiliary varieties. Let $\Sigma^+ = \Sigma \cup \{R_{\geq 0}e_k^i\}$ and $\Sigma^- = \Sigma' \cup \{R_{\geq 0}e_k\}$. We can blow up $X_{\Sigma^+}$ (resp. $X_{\Sigma^-}$) in the same way as we do so for $X_{\pi}$ (resp. $X_{\Sigma'}$) to obtain $\tilde{X}_+$ (resp. $\tilde{X}_-$). Removing the strict transforms of the toric boundaries, we can still get $U_\Lambda$ and $U_{\Lambda'}$. Following Lemma 3.6 in [GHK15], we show that $\mu_k$ extends to an isomorphism (outside codimension two subsets) between $\tilde{X}_+$ and $\tilde{X}_-$, mapping the toric boundary of one to that of the other.

Suppose we only blow up $X_{\Sigma^+}$ along $Z_k$ and $X_{\Sigma^-}$ along $Z_k'$. Then the blow-up $\tilde{X}_+$ has a covering of open subsets

\[(5.2)\]  
\[
\tilde{X}_+ = \tilde{P}_+ \cup \left( \bigcup_{i \neq k} U_i \right) \]

where $\tilde{P}_+$ is the blow-up along $Z_k$ of the toric variety of the fan $\{R_{\geq 0}e_k^i, R_{\geq 0}e_k\}$ and $U_i$ is the standard open toric chart corresponding to the ray $R_{\geq 0}e_i$. Replacing $U_i$ with $U_i \setminus \tilde{V}(f_k)$ for $i \neq k$, (5.2) is still a covering but up to codimension two (with $\tilde{V}(f_k) \cap D_i$ missing). More precisely, $f_k$ is a regular function on $U_i$ if $(w_k, e_i) \geq 0$. In this case, $\tilde{V}(f_k) \cap D_i$ is just the zero locus of the restriction of $f_k$ on $D_i$, i.e. $V(f_k) \cap D_i$. As $z^w$ vanishes on $Z_i$ when $(w_k, e_i) > 0$, $\tilde{V}(f_k) \cap D_i = \emptyset$ since $f_k$ has non-zero constant term. When $(w_k, e_i) < 0$, then $\tilde{V}(f_k) \cap D_i = V(z^{-r_k w_k} f_k) \cap D_i$ where $z^{-r_k w_k} f_k$ is a regular function on $U_i$. So $\tilde{V}(f_k) \cap D_i$ is still empty since $f_k'$ has non-zero constant. Therefore we only fail to cover $V(f_k) \cap D_i$ when $(w_k, e_i) = 0$, which is a codimension two subset.

By Lemma 3.2 of [GHK15], $\mu_k$ extends to a regular isomorphism from $\tilde{P}_+$ to $\tilde{P}_-$. Here $\tilde{P}_-$ is the blow-up along $Z_k'$ of the toric variety defined by the fan $\{R_{\geq 0}e_k^i, R_{\geq 0}e_k\}$. We check that $\mu_k$ also extends to a regular isomorphism from $U_i \setminus \tilde{V}(f_k)$ to $U_i' \setminus \tilde{V}(f_k')$. Note that these are affine schemes so we check that $\mu_k'$ extends to an isomorphism between their rings of regular functions. There are two cases.

1. If $\langle e_i, w_k \rangle \geq 0$, then $e_i' = e_i$. Note that $f_k$ is a regular function on $U_i$ as well as on $U_i'$. Thus we have

\[U_i \setminus \tilde{V}(f_k) = U_i \setminus V(f_k) \quad \text{and} \quad U_i' \setminus \tilde{V}(f_k') = U_i' \setminus V(f_k').\]

For $\langle m, e_i \rangle \geq 0$, $z^m$ defines a regular function on $U_i'$ and

$\mu_k'(z^m) = z^m f_k^{-(m,e_k)}$ is a regular function on $U_i \setminus V(f_k)$.

2. If $\langle e_i, w_k \rangle < 0$, then $e_i' = e_i - \langle e_i, r_k w_k \rangle e_k$. Instead of $f_k$, the function $f_k' = z^{-r_k w_k} f_k$ is a regular function on $U_i$ and $V(f_k') = V(f_k')$. For $\langle m, e_i' \rangle \geq 0$ and $z^m$ a regular function on $U_i'$, we have

$\mu_k'(z^m) = z^m f_k^{-(m,e_k)} = z^{m-r_k w_k(m,e_k)} (f_k')^{-\langle m, e_k \rangle}.$
We check that \( \langle m - r_k w, m, e_k \rangle, e_i \rangle = \langle m - r_k w, m, e_k \rangle, e_i' + \langle e_i, r_k w \rangle e_k \rangle = \langle m, e_i' \rangle > 0. \)

Thus \( \mu_k^*(z^m) \) is a regular function on \( U_i \setminus \bar{V}(f_k) = U_i \setminus \bar{V}(f_k') \).

Therefore \( \mu_k^* \) is a morphism between regular functions. In all the cases above, one checks that sending \( z^m \) to \( z^m f_k'^{(m,e_k)} \) is the inverse of \( \mu_k^* \). Summarizing, we have so far proven that there is an isomorphism

\[
\mu_k: U_+ := \tilde{\mathbb{P}}_+ \cup \left( \bigcup_{i \neq k} U_i \setminus \bar{V}(f_k) \right) \to U_- := \tilde{\mathbb{P}}_- \cup \left( \bigcup_{i \neq k} U'_i \setminus \bar{V}(f_k') \right)
\]

extending the birational morphism \( \mu_k \) between tori.

Now we analyze the impact of blowing up the hypersurfaces \( Z_i \) (and \( Z'_i \)) for \( i \neq k \). When \( \langle w_k, e_i \rangle \neq 0 \), as discussed \( D_i \cap V(f_k) = \emptyset \), so \( Z_i \subset D_i \) is contained in \( U_+ \). Since \( \langle w_k', e_i \rangle = -\langle w_k, e_i \rangle \neq 0 \), the same is true for \( Z'_i \), i.e. \( Z'_i \subset U_- \). We would like to show that \( \mu_k(Z_i) = Z'_i \) when \( \langle w_k, e_i \rangle \neq 0 \). There are two cases.

1. Suppose \( \langle w_k, e_i \rangle > 0 \). In this case, \( e_i' = e_i \) and \( w_i' = w_i \). By definition \( Z'_i = D_i' \cap V(f_i'') = V(z^{m_0}) \cap V(f_i'') \subset U_i' \) for some \( m_0 \) such that \( \langle m_0, e_i \rangle = 1 \). Now we have \( \mu_k^*(z^{m_0}) = z^{m_0} f_k^{-(m_0, e_k)} \) and

\[
\mu_k^*(f_i') = a'_i \cdot a_{i,0}^{-\beta_k} z^{w_i} + \cdots + a'_{i,r_i} z^{r_i w_i} f_k^{-(r_i, w_i)}.
\]

Note that \( f_k \) is invertible on \( U_i \setminus \bar{V}(f_k) \) and restricts to constant \( p_{k_0} \) on \( D_i \). So \( V(\mu_k^*(z^{m_0})) \) is just the divisor \( D_i \) and

\[
\mu_k^*(f_i')|_{D_i} = a'_i \cdot a_{i,0}^{-\beta_k} z^{w_i} + \cdots + a'_{i,r_i} z^{r_i w_i} = \lambda \cdot f_i |_{D_i},
\]

for some non-zero \( \lambda \in \mathbb{k} \) by the \( \mu_k \)-equivalence assumption on \( \Lambda \) and \( \Lambda' \). Therefore \( \mu_k(Z_i) = Z'_i \).

2. Suppose \( \langle w_k, e_i \rangle < 0 \). In this case we have \( e_i' = v_i - \langle r_k w, e_i \rangle e_k \) and \( w_i' = w_i + \langle w_i, e_k \rangle r_k w_k \).

Still \( Z'_i = V(z^{m_0}) \cap V(f_i'') \). Now instead of \( f_k \), the function \( f_k' = z^{r_k w_k} f_k \) is a regular function on \( U_i \) and restricts to constant \( a_{k,r_k} \) on \( D_i \). First, \( \mu_k^*(z^{m_0}) = z^{m_0 - \langle m_0, e_k \rangle} r_k w_k (f_k')^{(m_0, e_k)} \). Since \( f_k' \) is invertible on \( U_i \setminus \bar{V}(f_k) \), \( V(\mu_k^*(z^{m_0})) = D_i \) as \( \langle m_0 + \langle m_0, e_k \rangle r_k w_k, e_i \rangle = 1 \). Secondly we have

\[
\mu_k^*(f_i') = a'_i \cdot a_{i,0}^{-\beta_k} z^{w_i} + \cdots + a'_{i,r_i} z^{r_i w_i} f_k^{-(r_i, w_i, e_k)}
\]

\[
= a'_i \cdot a_{i,0}^{-\beta_k} z^{w_i'}(r_k w_k) (f_k')^{-\langle r, w_i \rangle} + \cdots + a'_{i,r_i} z^{r_i w_i'}(r_k w_k) (f_k')^{-\langle r, w_i \rangle}
\]

Hence

\[
\mu_k^*(f_i')|_{D_i} = a'_i \cdot a_{i,0}^{-\beta_k} z^{w_i} + \cdots + a'_{i,r_i} a_{k,r_k}^{-\beta_k} z^{r_i w_i} = \lambda \cdot f_i |_{D_i},
\]

for some non-zero \( \lambda \in \mathbb{k} \) again by the \( \mu_k \)-equivalence assumption. Therefore in this case we also have \( \mu_k(Z_i) = Z'_i \).

Finally we consider the case \( \langle w_k, e_i \rangle = 0 \). The argument we need is exactly the same as in the last paragraph of the proof in [GHK15]. By the assumption \( \langle w_k, e_i \rangle = 0 \implies \langle w_i, e_k \rangle = 0 \), so we have

\[
\mu_k^*(f_i') = f_i,
\]

and thus \( \mu_k(Z_i) = Z'_i \). The problem is that \( Z_i \) may not be fully contained in \( D_i \setminus \bar{V}(f_k) \), with \( V(f_k) \cap Z_i \) missing. If \( V(f_k) \cap Z_i \) contains an irreducible component of \( Z_i \), then \( U_\Lambda \) would contain the corresponding exceptional divisor while blowing up in \( U_+ \) does not. However the isomorphism \( \mu_k: U_+ \to U_- \) need not extend as isomorphism across this exceptional divisor. Now we need the further hypothesis \( \dim V(f_k) \cap Z_i < \dim Z_i \) so that the missing part in the blow-up center is of at
least codimension three in \( U_i \). After blowing up the corresponding locus in \( U_+ \) and \( U_- \), we have the following diagram

\[
\begin{array}{ccc}
\tilde{U}_+ & \xrightarrow{\mu_k} & \tilde{U}_- \\
\downarrow{\pi} & & \downarrow{\pi} \\
U_+ & \xrightarrow{\mu_k} & U_- \\
\end{array}
\]

where vertical arrows are blow-ups and horizontal arrows are genuine isomorphisms. Removing the strict transform of the toric boundary, we have immersions

\[
\tilde{U}_+ \setminus \tilde{D} \subset U_\Lambda \quad \text{and} \quad \tilde{U}_- \setminus \tilde{D} \subset U_\Lambda'.
\]

missing codimension two loci. Summarizing, the birational map \( \mu_k \) can be extended to an isomorphism \( \mu_k : U_\Lambda \rightarrow U_\Lambda' \) outside sets of codimension two. \( \square \)

We state a sufficient condition for the assumption in Theorem 5.4,

\[
\forall (e_i, w_k) = 0, \quad \dim \tilde{V}(f_k) \cap Z_i < \dim Z_i,
\]

to hold.

**Definition 5.5** (cf. \[BFZ05, Definition 1.4\]). A toric model data \( \Lambda = ((e_i), (w_i), (f_i)) \) is said to be **coprime** if the functions \( f_i \) are pairwise coprime as elements in the ring \( k[M] \).

**Corollary 5.6.** The result in Theorem 5.4 holds if \( \Lambda \) is coprime.

**Proof.** Note that \( Z_i = \tilde{V}(f_i) \cap D_i \). If needed, multiply some monomial \( z^m \) to \( f_i \) so that \( \tilde{f}_i = z^m f_i \) is a regular function on \( D_i \). Do the same to \( f_k \) to get \( \tilde{f}_k \). By the coprime condition on \( \Lambda \), \( \tilde{f}_i \) and \( \tilde{f}_k \) are still coprime, so we have

\[
\dim V(\tilde{f}_k) \cap V(\tilde{f}_i) < \dim V(\tilde{f}_i)
\]

where the above subschemes are taken inside \( D_i \). \( \square \)

The following is an easy-to-check condition on \( \Lambda \) for the coprimeness to hold.

**Lemma 5.7.** If the vectors \( w_i \) are linear independent, then \( \Lambda \) is coprime.

5.2. **The upper bound.** Suppose we are given the data \( \Lambda = ((e_i), (w_i), (f_i)) \). Assume that \( \Lambda \) is \( i \)-mutable for any \( i \in I \). For \( i \in I \), let \( T_N^{(i)} \) be a copy of the torus \( T_N \). Then we have birational maps for each \( i \in I \),

\[
\mu_i : T_N \dashrightarrow T_N^{(i)}, \quad \mu_i^*(z^m) = z^m f_i^{-(e_i,m)}.
\]

We glue the \( |I| + 1 \) tori along the maps \( \mu_i \) to obtain a scheme \( X_\Lambda \).

In previous section, we know that not only the torus \( T_N, U_\Lambda \) also contains the torus \( T_N^{(i)} \), that is, we have the following diagram for every \( i \in I \):

\[
\begin{array}{ccc}
T_N & \xrightarrow{\mu_i} & T_N^{(i)} \\
\downarrow{\Sigma} & & \\
U_\Sigma & & \\
\end{array}
\]

These diagrams determine a unique morphism \( \psi : X_\Lambda \rightarrow U_\Lambda \).

**Lemma 5.8** ([GHK15, Lemma 3.5]). The morphism \( \psi : X_\Lambda \rightarrow U_\Lambda \) satisfies the following properties

1. If \( \dim Z_i \cap Z_j < \dim Z_i \) for all \( i \neq j \), then \( \psi \) is an isomorphism outside a set of codimension at least two.
2. If \( Z_i \cap Z_j = \emptyset \) for all \( i \neq j \), then \( \psi \) is an open immersion. In particular, in this case, \( X_\Lambda \) is separated.
In the $\mathcal{A}$-cluster case to be explained later, the variety $X_{\mathcal{A}}$ may be named the upper bound according to [FZ07].

5.3. Toric models for cluster varieties. In this section, we realize generalize cluster varieties as log Calabi–Yau varieties utilizing Construction 5.1.

5.3.1. $\mathcal{A}$-cluster cases. Suppose we have fixed data $\Gamma$ and an $\mathcal{A}$-seed with coefficients $s = (e, p)$. We further choose an evaluation $\lambda: \mathbb{P} \to \mathbb{k}^*$. This amounts to pick a $k$-point of Spec$(\mathbb{k}[\mathbb{P}])$. These lead to the generalized $\mathcal{A}$-cluster variety $\mathcal{A}_{s, \lambda}$ with special coefficients.

Meanwhile consider the toric model data

$$\Lambda(s, \lambda) := ((e_i)_{i \in I_{af}}, (w_i)_{i \in I_{af}}, (f_i)_{i \in I_{af}})$$

defined as follows. The vectors $(e_i)_{i \in I_{af}}$ are taken from the seed $s$. Recall that we have the exchange matrix $B = (b_{ij})$ where $b_{ij} := \omega(e_i, d_j e_j)$. Write $\beta_{ij} = b_{ij}/r_j$. Note that $\{e_i \mid i \in I\}$ form a basis of the lattice $N$ and we denote by $e_i^*$ the dual basis of $M$. Then define

$$w_i := \omega(-, d_i e_i/r_i) = \sum_{j \in I} \beta_{ij} e_j^* \in M, \quad f_i := \lambda(\theta[p_i](z^{w_i}, 1)) \in k[M].$$

Then Construction 5.1 applies to the toric model data $\Lambda(s, \lambda)$, and thus there is the associated log Calabi–Yau variety $U_{\Lambda(s, \lambda)}$. Recall that we also have the scheme $X_{\Lambda(s, \lambda)}$ obtained by glueing $n+1$ copies of the torus $T_N$ as in Section 5.2. We call $X_{\Lambda(s, \lambda)}$ the upper bound for $(s, \lambda)$, which by definition is an open subscheme of $\mathcal{A}_{s, \lambda}$.

The following lemma is easy to verify by direct computations.

Lemma 5.9. We have $\mu_k(\Lambda(s, \lambda)) = \Lambda(\mu_k(s), \lambda)$ in the sense of Definition 5.3. The later $\mu_k$ is the mutation of an $\mathcal{A}$-seed with coefficients.

Proposition 5.10. We have

1. the morphism $\psi: X_{\Lambda(s, \lambda)} \to U_{\Lambda(s, \lambda)}$ is an open immersion with image an open subset whose complement has codimension at least two;
2. the birational map $\mu_k: U_{\Lambda(s, \lambda)} \dashrightarrow U_{\Lambda(\mu_k(s), \lambda)}$ is an isomorphism outside codimension two in each of the listed situations
   A. the functions $f_i$ have general coefficients;
   B. the seed $s$ is mutation equivalent to one with principal coefficients, and $\lambda \in (\mathbb{k}^*)^{I_{af}}$ is general enough.

Proof. (1) follows from Lemma 5.8, part (2) - as we only need to check the hypothesis $Z_i \cap Z_j = \emptyset$ for all $i \neq j$. In fact, in the $\mathcal{A}$-cluster case, since $e_i \neq e_j$, we have $T_{N/(e_i)} \cap T_{N/(e_j)} = \emptyset$ for all $i \neq j$ where $T_{N/(e_i)}$ is viewed as the dense torus contained in the divisor $D_i$. As $Z_i$ is a closed subset of $T_{N/(e_i)}$, the hypothesis holds.

(2) follows from Theorem 5.4. We need to check that whenever $\langle e_i, u_k \rangle = 0$,

$$\dim V(f_k) \cap V(f_i) \cap D_i < \dim V(f_i) \cap D_i.$$

A sufficient condition is the functions $f_i$ being coprime. Note that for $i \in I$,

$$f_i = \prod_{j=1}^{r_i} (\lambda(p_{i,j}^+) z^{w_i} + \lambda(p_{i,j}^-)).$$

When these $f_i$ have general coefficients (case A), they are coprime. In case B, one may replace $f_i$ by

$$\tilde{f}_i = \prod_{j=1}^{r_i} (\lambda(p_{i,j}) z^{w_i} + 1).$$
Since the elements $p_{i,j}$ for $i \in I$ and $j \in [1, r_i]$ form a $\mathbb{Z}$ basis in $P$ (by Lemma 3.18) when $s$ is mutation equivalent to one with principal coefficients, these $\tilde{f}_i$ are coprime as long as $\lambda$ is general. □

**Remark 5.11.** Suppose we are in the situation of case B of Proposition 5.10, (2). Then we have isomorphisms of the rings of regular functions

$$k[X_{\Lambda(s, \lambda)}] \cong k[U_{\Lambda(s, \lambda)}] \cong k[U_{\Lambda(\mu_k(s), \lambda)}].$$

The equality then extends to any seed $s$, that is mutation equivalent to $s$. It then follows that they are all isomorphic to the upper cluster algebra

$$\mathcal{A}(s, \lambda) = k[A_{s, \lambda}].$$

The cluster variables in seed $s$ are $x_{i,s} := z^{e_i}$. Each $x_{i,s}$ extends to a regular function on the toric variety $X_\Sigma$ corresponding to the toric model data $\Lambda(s, \lambda)$. Then $x_{i,s}$ pulls back to the blow-up $\tilde{X}_\Sigma$ and restricts to a regular function on the open subvariety $U_{\Lambda(s, \lambda)}$. It follows from (2) of Proposition 5.10 that $x_{i,s}$ is also a regular function on $X_{\Lambda(s, \lambda)}$ and in particular is a Laurent polynomial if restricted to $T_{N, s}$. This explains the generalized Laurent phenomenon Theorem 3.7, which was observed in [GHK15] for the ordinary case.

### 5.3.2. $X$-cluster cases

Suppose we have fixed data $\Gamma$ and an $X$-seed with coefficients $s = (e, q)$. Let us make the assumption that for any $j \in I_{af}$,

$$r_j = \gcd(b_{ij}, i \in I).$$

This is equivalent to say that each $w_j$ for $j \in I_{af}$ is primitive as an element of $M = \text{Hom}(N, \mathbb{Z})$. Switching the roles of $(e_i)$ and $(w_i)$, we obtain the toric model data

$$\Omega(s, \lambda) = ((-w_i), (e_i), (g_i))$$

for $M$ instead of $N$, where

$$g_i := \lambda(\theta[q_i](z^{e_i}, 1)) \in k[N]$$

with some chosen evaluation $\lambda$. Since the matrix $B$ is skew-symmetrizable, $\Omega(s, \lambda)$ is $k$-mutable for any $k \in I_{af}$.

**Lemma 5.12.** The assumption that $r_j = \gcd(b_{ij}, i \in I)$ is invariant under mutations.

**Proof.** This is because if the $j$-th column of $B$ is divisible by $r_j$ then the same is true for the matrix $\mu_k(B) = (b'_{ij})$. Thus we have

$$\gcd(b_{ij}, i \in I) = \gcd(b'_{ij}, i \in I)$$

as $\mu_k$ is involutive on $B$. □

The above lemma shows that we have well-defined data $\Omega(\mu_k(s), \lambda)$.

**Lemma 5.13.** We have $\mu_k(\Omega(s, \lambda)) = \Omega(\mu_k(s), \lambda)$, where the later $\mu_k$ is the mutation for an $X$-seed with coefficients.

**Proof.** This lemma is analogous to Lemma 5.9 and is also easy to check. However, to show that the carefully chosen signs and conventions are the correct ones, we record some details here.

In the notations of Definition 5.3, for the data $\Omega(s, \lambda)$, we take $e_i = -w_i$ and $w_i = e_i$. So after the mutation $\mu_k$ in sense of Definition 5.3, for $i \neq k$

$$(-w_i)' = \begin{cases} -w_i - ((-w_i), r_k e_k)(-w_k) & \text{if } (-w_i, e_k) \leq 0 \\ -w_i & \text{if } (-w_i, e_k) > 0. \end{cases}$$
Note that the two conditions are equivalent to $\beta_k \leq 0$ and $\beta_k > 0$ respectively. And in these two cases, we have

$$(-w_i)' = -w_i - (e_k, w_i) r_k w_i \quad \text{and} \quad -w_i$$

respectively. This is exactly $-w'_i$ for $w'_i = \omega(-, c_i e'_i/r_i)$ from the seed $\mu_k(s)$. Similarly, one checks that the e part is also compatible with mutations.

As for coefficients, for the data $\Omega(\mu_k(s), \lambda)$, we have

$$g_i(u, v) = \lambda(\theta[q'_i(u, v)]).$$

Here $q'_i$ is obtained from $X$-type mutations for coefficients (see Definition 4.14) which coincides with Definition 5.3.

Recall that $X_{\Omega(s, \lambda)}$ is the upper bound for $\Omega(s, \lambda)$ as defined in Section 5.2.

**Proposition 5.14.** We have (for the $X$-type constructions)

1. the morphism $\psi: X_{\Omega(s, \lambda)} \to U_{\Omega(s, \lambda)}$ is an open immersion with image being an open subset whose complement has codimension at least two;

2. the birational map $\mu_k: U_{\Omega(s, \lambda)} \dashrightarrow U_{\Omega(\mu_k(s), \lambda)}$ is an isomorphism outside codimension two subsets.

**Proof.** The proof of (1) is completely analogous to the one of (1) of Proposition 5.10. For (2), it follows from that for any $X$-seed $s$, the data $\Omega(s, \lambda)$ is always coprime by Lemma 5.7 as the vectors $e_i$ form a basis of $N$. □

### 6. Scattering diagrams

This section deals with scattering diagrams. Our main objects of study generalized cluster scattering diagrams will be defined in Section 6.2.

**6.1. The tropical vertex.** We start with a more general setup of scattering diagrams as in [AG22, Section 5.1.1]. Let $N$ be a lattice of finite rank, $M = \text{Hom}_\mathbb{Z}(N, \mathbb{Z})$ and $M_\mathbb{R} = M \otimes \mathbb{R}$. Let $P$ be a monoid with a monoid map $r: P \to M$. Denote by $P^\times$ the groups of units of $P$ and let $m_P = P \setminus P^\times$.

An ideal of the monoid $P$ induces a monomial ideal of the ring $k[P]$ where $k$ is a ground field. So we use the same letter to denote both. For any monomial ideal $I \subset k[P]$, define the ring

$$R_I := k[P]/I.$$

Denote by $\overline{k[P]}$ the completion of $k[P]/m_P^n$ for $n \in \mathbb{N}$.

For $I$ such that its radical $\sqrt{I}$ is equal to $m_P$ (e.g. $I = m_P^n$ for some $n \in \mathbb{N}$), define the **module of log derivations** $\Theta(R_I) := R_I \otimes_\mathbb{Z} N$ as follows.

If we write the element $z^p \otimes n$ as $z^p \partial_n$ for $p \in P$ and $n \in N$, then it acts on $R_I$ by

$$z^p \partial_n(z^{p'}) = (n, r(p'))z^{p+p'}, \quad p' \in P.$$

Then the submodule $m_P\Theta(R_I)$ is a Lie algebra with the commutator bracket

$$[z^{p_1} \partial_{n_1}, z^{p_2} \partial_{n_2}] = z^{p_1+p_2} \partial_{(r(p_2), n_1)n_2-(r(p_1), n_2)n_1}.$$

Taking exponential of elements in this Lie algebra, we get group elements in $\text{Aut}(R_I)$. There is a nilpotent Lie subalgebra of $m_P\Theta(R_I)$ defined by

$$\mathfrak{v}_I := \bigoplus_{m \in P\setminus I, r(m) \neq 0} z^m (k \otimes r(m)^\perp).$$

Since it is nilpotent, this Lie subalgebra (as a set) is in bijection with the corresponding algebraic group $V_I := \text{exp}(\mathfrak{v}_I) \subset \text{Aut}(R_I)$. Taking the projective limit with respect to the ideals $m_P^n$ for $n \in \mathbb{N}$,
we get a pro-unipotent group $\hat{V}$, which is in bijection with the pro-nilpotent Lie algebra $\hat{v} := \varprojlim_{m \in \mathbb{Z}_{>0}} \mathfrak{v}$. The group $\hat{V}$ is called the higher dimensional tropical vertex group, acts by automorphisms on $\mathfrak{k}[\hat{P}]$.

We also denote (without completion)

$$v := \bigoplus_{m \in P, r(m) \neq 0} z^m (k \otimes r(m)^\perp).$$

**Definition 6.1.** A scattering diagram in $M_\mathbb{R}$ over $R_I$ is a finite set $\mathcal{D}$ of walls where each wall $(\mathfrak{d}, f_\mathfrak{d})$ is a rational polyhedral cone $\mathfrak{d} \subset M_\mathbb{R}$ of codimension one along with an attached element called wall-crossing function

$$f_\mathfrak{d} = \sum_{m \in P, r(m) \not\in \Lambda_0} c_m z^m \in R_I,$$

where $\Lambda_0 \subset M$ is the integral tangent space of any point in $\mathfrak{d}$, i.e. $\Lambda_0 = M \cap R(\mathfrak{d})$. We require that $f_\mathfrak{d} \equiv 1 \mod m_P$.

**Remark 6.2.** Upon choosing a generator $n_0$ of $\Lambda_0^\perp \cap N$, the wall-crossing function $f_\mathfrak{d}$ induces an element in $\mathcal{V}_I \subset \text{Aut}(R_I)$ by the action

$$z^p \mapsto z^p f_\mathfrak{d}^{(r(p), n_0)}.$$  

So this wall-crossing automorphism depends on how one crosses the wall. One may view that this wall-crossing automorphism depends on the direction in which one transversally crosses the wall. With $n_0$ chosen, such an automorphism can be equivalently represented by the corresponding Lie algebra element $\log(f_\mathfrak{d}) \partial_{n_0} \in \mathfrak{v}_I$.

Let $\text{Supp}(\mathcal{D})$ be the union of all walls in $\mathcal{D}$. Let $\text{Sing}(\mathcal{D})$ be the union of at least codimension two intersections of every pair of walls and the boundary of every wall. Let $\gamma : [0, 1] \to M_\mathbb{R}$ be a piecewise smooth proper map such that the end points $\gamma(0)$ and $\gamma(1)$ avoid $\text{Supp}(\mathcal{D})$ and whose image is disjoint from $\text{Sing}(\mathcal{D})$. We also assume that $\gamma$ meets walls transversally.

Suppose that $\gamma$ crosses walls $\mathfrak{d}_1, \ldots, \mathfrak{d}_s$ in $\mathcal{D}$ at times

$$0 < t_1 \leq t_2 \leq \cdots \leq t_s < 1.$$  

These numbers $t_i$ are obtained by considering the finite set $\gamma^{-1}(\text{Supp}(\mathcal{D})) \subset [0, 1]$ as $\gamma$ is proper. It is possible that $t_i = t_j$ as walls may overlap. Suppose $\gamma$ crosses a wall $(\mathfrak{d}, f_\mathfrak{d})$ at time $t$. Denote by $\xi_{\gamma, \mathfrak{d}}$ the element in $\mathcal{V}_I$ with the action

$$z^p \mapsto z^p f_\mathfrak{d}^{(r(p), n_0)}, \quad p \in P \setminus I$$

where $n_0$ is chosen such that $\langle n_0, \gamma'(t_i) \rangle > 0$.

**Definition 6.3.** We define the path-ordered product of $\gamma$ in $\mathcal{D}$ to be the element

$$p_{\gamma, \mathcal{D}} := \xi_{\gamma, \mathfrak{d}_1} \xi_{\gamma, \mathfrak{d}_2} \cdots \xi_{\gamma, \mathfrak{d}_s} \in \mathcal{V}_I.$$

**Definition 6.4.** A scattering diagram $\mathcal{D}$ over $R_I$ is consistent if the path-ordered product $p_{\gamma, \mathcal{D}}$ only depends on the endpoints $\gamma(0)$ and $\gamma(1)$ for any path $\gamma : [0, 1] \to M_\mathbb{R}$ for which $p_{\gamma, \mathcal{D}}$ is well-defined.

Recall that we have the completed algebra $\mathfrak{k}[\hat{P}] := \varprojlim_{m \in \mathbb{Z}_{>0}} R_{m_P}$. For an element $f \in \mathfrak{k}[\hat{P}]$, denote by $f^{<k}$ its projection in $R_{m_P}$.

**Definition 6.5.** A scattering diagram in $M_\mathbb{R}$ over $\mathfrak{k}[\hat{P}]$ is a (possibly infinitely) set $\mathcal{D}$ of walls $(\mathfrak{d}, f_\mathfrak{d})$ with $\mathfrak{d}$ a rational polyhedral cone of codimension one and the wall-crossing function

$$f_\mathfrak{d} = \sum_{m \in P, r(m) \not\in \Lambda_0} c_m z^m \in \mathfrak{k}[\hat{P}],$$
such that modulo the ideal $m^n$, the collection $D^{<n} := \{(d, f^{<n}_d)\}$ is a scattering diagram over $R_{m^n}$. A scattering diagram $D$ is consistent if $D^{<n}$ is consistent for any $n \in \mathbb{N}$.

The path-ordered product for $D$ over $k[P]$ is defined through the projective limit of path-ordered products for $D^{<n}$:

$$p_{\gamma, D} := \lim_{\leftarrow n} p_{\gamma, D^{<n}} \in \hat{\mathcal{V}} \subset \text{Aut}(k[P]).$$

**Definition 6.6.** We say two scattering diagrams $D$ and $D'$ (over the same algebra) are equivalent if for any $\gamma$, we have $p_{\gamma, D} = p_{\gamma, D'}$ whenever both path-ordered products are well-defined.

**Definition 6.7.** We say a wall $d$ has direction $m_0$ for some $m_0 \in M$ if the attached wall-crossing function $f_d$ only contains monomials $z^p$ such that $r(p) = km_0$ for some $k \in \mathbb{N}$. A wall $(d, f_d)$ with direction $m_0$ is called incoming if $d = d - R_{\geq m_0}$.

Next we explain how to assign a scattering diagram to an $X$-type toric model. We are actually in a particular situation within the more general framework of [AG22], which works for any log Calabi–Yau variety obtained from blowing-up a toric variety along hypersurfaces in the toric boundary. Let $s = (e, q)$ be an $X$-seed with principal coefficients for some fixed data $\Gamma$. We assume that $N_{\text{aff}} = N$ to avoid frozen directions. As usual, write $e = (e_i)$. We assume the condition that $r_i = \gcd(h_{ij} \mid i \in I)$ for any $j \in I$. This assumption implies any $w_i := \frac{d_i}{r_i} \omega(-, e_i) \in M$ is primitive. Recall that we have used the fan

$$\Sigma_0 := \{0\} \cup \{-R_{\geq 0}w_i\}$$

to describe the toric model of $U = U_{\Omega(s, \lambda)}$. The functions (in the data $\Omega(s, \lambda)$ to define $U$) are then

$$g_i = \prod_{j=1}^{r_i} (1 + \lambda_{ij} z^{e_i}) \in k[N].$$

We pick a complete fan $\Sigma$ in $M_\mathbb{R}$ containing $\Sigma_0$. For example, we may take a refinement of (the cone complex induced by) the hyperplane arrangement $\{e_i^+ \mid i \in I\}$. Let $X_\Sigma$ be the corresponding (complete) toric variety, with $D_i$ being the boundary toric divisor corresponding to the ray $-R_{\geq 0}w_i$. Let $H = \bigcup_i H_i$ where

$$H_i = \bigcup_{j \in [1, r_i]} H_{ij} := \bigcup_{j \in [1, r_i]} \mathcal{V}(1 + \lambda_{ij} z^{e_i}) \cap D_i$$

which is a union of disjoint hypersurfaces in $D_i$ (as the coefficients $\lambda_{ij} \in \mathbb{K}^*$ are general). These hypersurfaces are exactly where we blow up $X_\Sigma$ to obtain the log Calabi–Yau variety $U_{\Omega(s, \lambda)}$.

Take the monoid

$$P := M \oplus \prod_{i \in I} \mathbb{N}^{r_i},$$

with the natural projection $r: P \rightarrow M$. We write multiplicatively $t_{i,1} t_{i,2} \ldots t_{i,r_i}$ for the generators of $\mathbb{N}^{r_i}$. For each ray $\rho_i := -R_{\geq 0}w_i$ and $H_{ij}$, there is a finite scattering diagram $D_{ij}$ called a widget from a certain tropical hypersurface [AG22, Definition 5.3 and Section 5.1.3]. In our case, they are given by

**Lemma 6.8.** The widget $D_{ij}$ consists of all codimension one cones of the fan $\Sigma$ contained in the hyperplane $e_i^+$ containing $\rho_i$, with the same wall-crossing function $(1 + t_{i,j} z^{w_i})$. In other words, we have

$$D_{ij} = \{ (\sigma, 1 + t_{i,j} z^{w_i}) \mid \sigma \in \Sigma, \dim \sigma = n-1, \sigma \subset e_i^+, \rho_i \subset \sigma \}.$$

**Proof.** By definition [AG22, Definition 5.3 and Section 5.1.3], $D_{ij}$ consists of walls $(\sigma, (1 + t_{i,j} z^{w_i})^{\omega_{\sigma}})$ where $\sigma$ runs through all codimension one cones in $\Sigma$ containing $\rho_i$ and $\omega_{\sigma} = H_{ij} \cdot \sigma$ is the intersection number computed in the divisor $D_i$. Here $D_\sigma$ is the one dimensional toric stratum in $D_i$ corresponding to $\sigma$. Note that if $e_i \notin \sigma^{\perp}$, then $z^{\omega_{\sigma}}$ or $z^{-e_i}$ vanishes along $D_\sigma$. So $H_{ij} = \mathcal{V}(1 + \lambda_{ij} z^{e_i})$ does not
intersect $D_\sigma$ and thus $\omega_\sigma = 0$. If $\sigma \subset e_i^\perp$, as $e_i$ is primitive, the intersection is at the point $z^e_i = -1/\lambda_{ij}$ where $z^e_i$ can be viewed as the coordinate on $D_\sigma$. Thus the multiplicity $\omega_\sigma$ is 1. \hfill \Box

Note that by Definition 6.7 every wall in $\mathcal{D}_{ij}$ is incoming since $-w_i$ is contained in every $\sigma$.

**Theorem 6.9** ([AG22, Theorem 5.6 and Section 5.1.3]). Consider the scattering diagram (with only incoming walls)

$$\mathcal{D}(X_\Sigma, H)_{\text{in}} := \bigcup_{i \in I} \bigcup_{j \in [1, r_i]} \mathcal{D}_{ij}.$$ 

There exists a unique (up to equivalence) consistent scattering diagram $\mathcal{D}(X_\Sigma, H)$ over $k[P]$ containing $\mathcal{D}(X_\Sigma, H)_{\text{in}}$ such that $\mathcal{D}(X_\Sigma, H) \setminus \mathcal{D}(X_\Sigma, H)_{\text{in}}$ consists only of non-incoming walls.

6.2. **Generalized cluster scattering diagrams.** Instead of applying Theorem 6.9 to $(X_\Sigma, H)$, there is another way to obtain the same scattering diagram by generalizing the construction of cluster scattering diagrams in [GHKK18].

Given fixed data $\Gamma$ and an $\mathcal{A}$-seed $s = (e, p)$ with principal coefficients, we are going to define the generalized cluster scattering diagram $\mathcal{D}_s$.

Recall that we have the semifield $P = \operatorname{Trop}(p)$, isomorphic to $\prod_{i \in I} \mathbb{Z}^{r_i}$ as an abelian group. Let $P = P_s$ as before be $M \oplus \prod_{i \in I} \mathbb{N}^{r_i}$, but regarded as a submonoid of $M \oplus P$ generated by $M$ and $p$. There is a submonoid $P^\oplus = P^\oplus_s \subset P$ generated by elements

$$\{(w_i, p_{ij}) \mid i \in I, j \in [1, r_i]\}.$$ 

One could take the completion of $P^\oplus$ with respect to the ideal $P^+ := P^\oplus \setminus \{0\}$, resulting $\widehat{k[P^\oplus]} \subset \overline{k[P]}$. In $N$, there is a submonoid $N_{s}^\oplus = N^\oplus$ generated by $\{e_i \mid i \in I\}$. Denote $N^+ = N^\oplus \setminus \{0\}$. We also consider the monoid map

$$\pi: P^\oplus \to N^\oplus, \quad (w_i, p_{ij}) \mapsto e_i.$$ 

Let $n = \sum_{i \in I} \alpha_i e_i \in N$. Define

$$\bar{n} := \sum_{i \in I} \alpha_i \cdot \frac{d_i}{r_i} e_i \in N_R.$$ 

These $\bar{n}$ form a sublattice $\overline{N}$ of $N_R$ isomorphic to $N$. We have the similar notion $\overline{N}^+$, the monoid generated by $\bar{e}_i$.

There is a subspace $\mathfrak{g}$ of the tropical vertex lie algebra $\mathfrak{v}$ defined as

$$\mathfrak{g} = \mathfrak{g}_s := \bigoplus_{n \in N^+} \mathfrak{g}_n, \quad \mathfrak{g}_n := \bigoplus_{\pi(p) = n} z^p \cdot (k \otimes \bar{n}) .$$

**Lemma 6.10.** The subspace $\mathfrak{g}$ is an $N^+$-graded Lie subalgebra of $\mathfrak{v}$.

**Proof.** For any $n = \sum_{i \in I} \alpha_i e_i \in N^+$, consider the elements

$$\prod_{i,j} p_{i,j}^{c_{i,j}} \cdot z^p^{(n)}$$

such that $\sum_{j \in [1, r_i]} c_{i,j} = \alpha_i$ and

$$p^*(n) := \omega(-, \bar{n}) = \sum_{i \in I} \alpha_i \omega(-, d_i e_i / r_i) = \sum_{i \in I} \alpha_i w_i.$$ 

Those elements form a basis of the vector space $\mathfrak{g}_n$. We check that for two such elements

$$\left[p_1 z^{p(n_1)} \partial_{n_1}, p_2 z^{p(n_2)} \partial_{n_2}\right] = p_1 p_2 \cdot z^{p(n_1 + n_2)} \partial_{\omega(n_1, n_2) n_2 - \omega(n_2, n_1) n_1} = \omega(n_1, n_2)p_1 p_2 \cdot z^{p(n_1 + n_2)} \partial_{n_1 + n_2} \in \mathfrak{g}_{n_1 + n_2}.$$ 

\hfill \Box
Remark 6.11. One may also view the above Lie algebra $\mathfrak{g}$ as being $\mathbb{N}^+$-graded where both $\mathbb{N}$ and $\mathbb{N}$ are sublattices of $\mathbb{N}_\mathbb{R}$. When later considering a scattering diagram $\mathcal{D}$ over an $\mathbb{N}^+$-graded Lie algebra $\mathfrak{g}$ (instead of $N^+$-graded), the walls live in $M_\mathbb{R}$ with integral normal vectors in $\mathbb{N}^+$.

Consider the ideals $(N^+)^k \subset N^+$ for $k \geq 1$. These correspond to the monomial ideals $(P^+)^k$. Then we have quotient Lie algebras (and their corresponding groups $G^{<k}$)

$$\mathfrak{g}^{<k} := \mathfrak{g}/(N^+)^k = \bigoplus_{n \in N^+ \setminus (N^+)^k} \mathfrak{g}_n,$$

and their projective limits

$$\hat{\mathfrak{g}} = \prod_{n \in N^+} \mathfrak{g}_n \quad \text{and} \quad G := \exp(\hat{\mathfrak{g}}).$$

The group $G^{<k}$ acts on $\mathbb{K}[P^\mathbb{R}]/(P^+)^k$ by automorphisms as in Remark 6.2.

For $n_0 \in N^+$ primitive, we define as in [GHKK18] a Lie algebra (and its corresponding pro-unipotent group)

$$\mathfrak{g}_{n_0}^\parallel := \bigoplus_{k \geq 0} \mathfrak{g}_{k-n_0} \subset \mathfrak{g} \quad \text{and} \quad G^\parallel_{n_0} := \exp(\mathfrak{g}_{n_0}^\parallel) \subset G.$$

There is a general framework for scattering diagrams over an $N^+$-graded Lie algebra (as opposed to the tropical vertex case); see [KS14, Section 2.1] and [GHKK18, Section 1.1]. In this case, one could make use of an existence-and-uniqueness theorem of [KS14] (see also [GHKK18, Theorem 1.21]) to obtain a consistent scattering diagram with certain prescribed incoming data. The cluster scattering diagram of [GHKK18] can be defined this way, which we will extend to the generalized case in Definition 6.17.

Definition 6.12. A wall in $M_\mathbb{R}$ (for $N^+$ and an $N^+$-graded Lie algebra $\mathfrak{g}$) is a pair $(\mathfrak{d}, g_\mathfrak{d})$ such that

1. $g_\mathfrak{d}$ belongs to $G^\parallel_{n_0}$ for some primitive $n_0 \in N^+$;
2. $\mathfrak{d} \subset n_0^+ \subset M_\mathbb{R}$ is a codimension one convex rational polyhedral cone.

Remark 6.13. The above definition works for general $N^+$-graded Lie algebras. In the case that $\mathfrak{g}$ is a Lie subalgebra of the tropical vertex Lie algebra $\mathfrak{v}$, the group $G^\parallel_{n_0}$ is embedded in $\text{Aut}(\mathbb{K}[P^\mathbb{R}])$. Then the wall-crossing element $g_\mathfrak{d}$ can be equivalently represented by a function $f_{\mathfrak{d}} \in \mathbb{K}[P^\mathbb{R}]$.

Now every wall has a direction $-p^\mathbb{R}(n_0) \in M$ in the sense of Definition 6.7. We call a wall $(\mathfrak{d}, g_\mathfrak{d})$ with direction $n_0$ incoming if $\mathfrak{d} = \mathfrak{d} - \mathbb{R}_{\geq 0}n_0$ and non-incoming (or outgoing) otherwise.

Definition 6.14. A scattering diagram over an $N^+$-graded algebra $\mathfrak{g}$ in $M_\mathbb{R}$ is a collection of walls such that for every degree $k > 0$, there are only a finite number of $(\mathfrak{d}, g_\mathfrak{d}) \in \mathcal{D}$ with the image of $g_\mathfrak{d}$ in $G^{<k}$ not being identity.

The path-ordered product of a path $\gamma : [0, 1] \rightarrow M_\mathbb{R}$ for a scattering diagram $\mathcal{D}$ over $\mathfrak{g}$ can be defined similarly as in Definition 6.3. We note that when $\gamma$ crosses a wall $(\mathfrak{d}, g_\mathfrak{d})$ at time $t$, then the element $\xi_{\gamma, \mathfrak{d}}$ also depends on $\gamma'(t)$:

$$\xi_{\gamma, \mathfrak{d}} = \begin{cases} g_\mathfrak{d} & \text{if } \langle n_0, \gamma'(t) \rangle > 0 \\ g_\mathfrak{d}^{-1} & \text{if } \langle n_0, \gamma'(t) \rangle < 0. \end{cases}$$

The consistency for these scattering diagrams is defined using path-ordered products in the same way as Definition 6.3.

Theorem 6.15 ([KS14, Proposition 2.1.12], [GHKK18, Theorem 1.21]). Let $\mathcal{D}_{\text{in}}$ be a scattering diagram over $\mathfrak{g}$ consisting only of incoming walls. Then there exists a unique (up to equivalence) consistent scattering diagram $\mathcal{D}$ containing $\mathcal{D}_{\text{in}}$ such that $\mathcal{D} \setminus \mathcal{D}_{\text{in}}$ consists only of outgoing walls.
Now we get back to the cluster situation. Suppose given fixed data $\Gamma$ and $s$ an $\mathcal{A}$-seed with principal coefficients. Unlike the previous section, here we do not assume the maximality of the positive integers $r_i$, i.e. $r_i$ needs not to be $\gcd(b_{k_i} \mid k \in I)$.

We calculate in the following how the group $G_{n_0}^\parallel$ is embedded in $\text{Aut}(\k[P^\parallel])$. Suppose $n_0 = \sum_{i \in I} \alpha_i e_i$, a primitive element in $N^+$. Consider any element

$$x = \sum_{k > 0} \sum_{\substack{p \in \mathbb{P}^\parallel \ni \pi(p) = k n_0}} \, c_p \cdot p \cdot z^{k p^* (n_0)} \partial_{k n_0} \in G_{n_0}^\parallel, \quad c_p \in \mathbb{k}.$$ 

For non-zero $n \in \mathbb{N}_Q$, denote by $\text{ind}(n)$ the largest number in $\mathbb{Q}_{\geq 0}$ such that $n/\text{ind}(n) \in N$. Thus $n/\text{ind}(n)$ is primitive in $N$.

**Lemma 6.16.** The group element $\exp(x) \in G_{n_0}^\parallel$ acts on $\k[P^\parallel]$ as an automorphism by

$$z^m \mapsto z^m \exp \left( \sum_{k > 0} \sum_{\substack{p \in \mathbb{P}^\parallel \ni \pi(p) = k n_0}} \, \text{ind}(n_0) k c_p \cdot p \cdot z^{k p^* (n_0)} \right) \partial_{k n_0/\text{ind}(n_0)}, \quad m \in P^\parallel.$$

**Proof.** This follows by rewriting $x$ as

$$x = \sum_{k > 0} \sum_{\substack{p \in \mathbb{P}^\parallel \ni \pi(p) = k n_0}} \, \text{ind}(n_0) k c_p \cdot p \cdot z^{k p^* (n_0)} \partial_{k n_0/\text{ind}(n_0)}.$$

Due to Lemma 6.16, any $\exp(x) \in G_{n_0}^\parallel$ can be represented by a function $f$ as in Lemma 6.16 such that the action of $\exp(x)$ sends $z^m$ to $z^m f^{(r(m), n_0/\text{ind}(n_0))}$.

Given $s = (e, p)$, for each $i \in I$, consider the hyperplane $e_i^+$ with the attached wall-crossing function

$$f_i = \prod_{j = 1}^{r_i} (1 + p_{i,j} z^{w_i}) \in \k[P^\parallel].$$

As discussed, the function $f_i$ represents an element in $G_{e_i^+}^\parallel$.

**Definition 6.17.** Let $\mathcal{D}_{s, \text{in}}$ be the scattering diagram over $\mathfrak{g}$ in $M_R$ consisting only of the incoming walls of the form $\partial_i := (e_i^+, f_i)$, i.e.

$$\mathcal{D}_{s, \text{in}} := \{(e_i^+, f_i) \mid i \in I\}.$$

We define the **generalized cluster scattering** $\mathcal{D}_s$ to be the unique (up to equivalence) consistent scattering diagram associated to $\mathcal{D}_{s, \text{in}}$ guaranteed by Theorem 6.15.

**Remark 6.18.** One may tend to think of $\mathcal{D}_s$ as a scattering diagram over $\k[P^\parallel]$ or over $\k[P]$ (as $\mathfrak{g}$ is a Lie subalgebra of $\mathfrak{v}$) in Definition 6.5. However there is one subtle issue. Suppose that there is a wall $(0 \subset n_0^\perp, f_0)$ in $\mathcal{D}_s$ for some $n_0 \in N^+$ primitive. Then the wall-crossing action is given by

$$\xi_{f_0}(z^p) = z^p f_0^{(n_0/\text{ind}(n_0), r(p))}.$$

Since in general $n_0$ may not be proportional to $n_0$, the cone $\mathcal{D}$ may not be contained in $n_0^\perp$. In this case, the wall $(\mathcal{D}, f_0)$ does not qualify as a wall in Definition 6.5. This issue can be resolved in the following two ways (so that one can view $\mathcal{D}_s$ as a scattering diagram of Definition 6.5).

1. We could regard $\mathfrak{g}$ as graded by $\mathcal{N}^\parallel \subset \mathbb{Q}_N$ (rather than $N^+$-graded) and modify Definition 6.12 (the definition of a wall $(\mathcal{D}, g_0)$) so that $\mathcal{D}$ is a codimension one cone in some hyperplane $n_0^\perp$ for $n_0 \in \mathcal{N}^\parallel$ and $g_0$ belongs to $G_{n_0}^\parallel$. 

34
(2) Another way to resolve the issue is to consider the dual \( \eta^* : M_R \to M_R \) of the linear map
\[
\eta : N_R \to N_R, \quad u \mapsto \bar{u}.
\]
We then apply \((\eta^*)^{-1}\) to every wall \((\bar{u}, f_0)\) to get the collection
\[
(\eta^*)^{-1}(D_\mathfrak{n}) := \{ ((\eta^*)^{-1}(\bar{u}), f_0) \mid (\bar{u}, f_0) \in D_\mathfrak{n} \}
\]
Then the cone \((\eta^*)^{-1}(\bar{u})\) is indeed contained in \(\hat{n}_D^+\). So this collection of walls is a scattering diagram in Definition 6.5.

From now on, to avoid any further confusion, the notation \( D_\mathfrak{n} \) is reserved for the consistent scattering diagram \((\eta^*)^{-1}(D_\mathfrak{n})\) over \( k[\overline{P}] \).

**Lemma 6.19.** Let \( s \) be a seed with principal coefficients for some generalized fixed data \( \Gamma \) (viewed of both \( A \)- and \( X \)-type) with the condition that for each \( i \in I \), the element
\[
w_i = \omega(-, d_i e_i / r_i)
\]
is primitive in \( M \). In this case, we have defined both scattering diagrams \( D_{(X, H)} \) (with a chosen general evaluation \( \lambda \)) and \( D_\mathfrak{s} \). Identify the parameters \( t_{i,j} \) with \( p_{i,j} \). Then \( D_{(X, H)} \) and \( D_\mathfrak{s} \) are equivalent as scattering diagrams over \( k[P] \).

**Proof.** We require \( \omega \) to be primitive so that \( D_{(X, H)} \) is defined. According to Remark 6.18, \( D_\mathfrak{s} \) is viewed as a scattering diagram over \( k[P] \) in the same \( M_R \) as \( D_{(X, H)} \) so it is legitimate to compare them. Let \( D \) be the consistent scattering diagram over \( \mathfrak{g} \) obtained using the initial data \( D_{(X, H), \text{in}} \). Notice that the walls in \( D_{(X, H), \text{in}} \) are parts of the hyperplanes \( e_i^+ \). We then subdivide the walls in \( D_{\mathfrak{s}, \text{in}} \), so that \( D_{(X, H), \text{in}} \) becomes the subset of incoming walls. Thus \( D \) is equivalent to \( D_\mathfrak{s} \) by Theorem 6.15.

On the other hand, \( D \) is also a scattering diagram over \( k[\overline{P}] \). By Theorem 6.9, It is also equivalent to \( D_{(X, H)} \) since they have the same incoming walls. Therefore we have \( D_{(X, H)} \cong D \cong D_\mathfrak{s} \).

### 6.3. The cluster scattering diagrams of GHKK

The ordinary cluster scattering diagram \( D_\mathfrak{s}^\text{ord} \) corresponds to the case where \( r_i = 1 \) for each \( i \in I \). Thus there is only one parameter \( p_i \) for each \( i \in I \). The lattice \( \overline{N} \) is generated by \( \overline{e}_i = d_i e_i \). The initial incoming walls are then
\[
\{(e_i^+, 1 + p_i z^{w_i}) \mid i \in I \},
\]
where \( w_i = \omega(-, \overline{e}_i) \in M \).

This scattering diagram is closely related to the cluster scattering diagram \( D_\mathfrak{s}^\text{GHKK} \) of Gross, Hacking, Keel and Kontsevich [GHKK18, Theorem 1.12]. We explain the difference and relation here. The scattering diagram \( D_\mathfrak{s}^\text{GHKK} \) is actually defined for \( \overline{N} \) and \( \overline{\overline{N}} := \text{Hom}(\overline{N}, \mathbb{Z}) \) (in the ordinary case equal to \( N^\circ \) and \( M^\circ \) respectively). Under the injectivity assumption [GHKK18, Section 1.1], the incoming walls are
\[
\left\{ \left( e_i^+, 1 + z^{\omega(e_i^-)} \right) \mid i \in I \right\}
\]
where \( \omega(e_i^-) \) is in \( M^\circ \). The injectivity assumption means that \( \omega(e_i^-) \) generate a strict convex cone. If this is not the case, we may extend \( M^\circ \) to \( M^\circ \oplus \mathbb{P} \) (identified with \( M^\circ \oplus N \) in [GHKK18]) and let incoming walls be
\[
\left\{ \left( e_i^+, 1 + p_i z^{\omega(e_i^-)} \right) \mid i \in I \right\}.
\]
It lives in \( (M^\circ \oplus N) \otimes \mathbb{R} \) or in \( M^\circ \otimes \mathbb{R} \) if regarding \( p_i \) as formal parameters as we do. Then \( D_\mathfrak{s}^\text{GHKK} \) is defined to be the unique consistent scattering diagram over \( k[\overline{P}] \) with only these incoming walls, where \( P \subset M^\circ \oplus N \) is a submonoid contained in a strictly convex cone and containing the cone generated by \( (p_i, \omega(e_i^-)) \). The Lie algebra \( \mathfrak{g} \), however, is naturally graded by \( N^+ \) (generated by \( e_i \)'s), not \( \overline{\overline{N}}^+ \) (generated by \( \overline{e}_i \)'s). Thus if one uses Theorem 6.15 to define \( D_\mathfrak{s}^\text{GHKK} \), the same rescaling issue in
Remark 6.18 still exists and can be resolved in a similar way. In [GHKK18], $\mathcal{D}_s^{GHKK}$ is regarded as living in $M_0^s$ with the integral normal vectors of walls being in $N^0$.

The structures of $\mathcal{D}_s^{GHKK}$ and $\mathcal{D}_s^{ord}$ are very much alike. For example, they both admit cluster complex structures; see [GHKK18, Theorem 2.13] and Theorem 7.10. It turns out that in the convention of [FZ07] (e.g. the definition of $g$-vectors), $\mathcal{D}_s^{GHKK}$ corresponds to the cluster algebra associated to $-B^T$ while $\mathcal{D}_s^{ord}$ corresponds to the one associated to $B$, where $B = (b_{ij})$ with $b_{ij} = \omega(e_i, e_j)$.

6.4. **Scattering diagrams with special coefficients.** Just as specializing a cluster algebra $\mathcal{A}$ at some evaluation $\lambda: \mathbb{P} \to k^*$, one can do the same to $\mathcal{D}_s$, obtaining a consistent scattering diagram with special coefficients.

We consider another monoid $Q = M \oplus \prod_{i \in I} \mathbb{N}$ (with $t_i$ being the standard generators of $\prod_{i \in I} \mathbb{N}$). Let $\lambda: \mathbb{P} \to k^*$, $p_{i,j} \mapsto \lambda_{i,j}$ be an evaluation. Define the map (abusing the same notation $\lambda$)

$$\lambda: k[P] \to k[Q], \ z^m \mapsto z^m \text{ for } m \in M, \ p_{i,j} \mapsto \lambda_{i,j}t_i.$$  

**Lemma 6.20.** The collection

$$\lambda(\mathcal{D}_s) := \{ (\mathfrak{d}, \lambda(f)) \mid (\mathfrak{d}, f) \in \mathcal{D}_s \}$$

obtained by applying the algebra homomorphism $\lambda$ to every wall-crossing function $f_0$ is a consistent scattering diagram over $k[Q]$.

**Proof.** The algebra homomorphism $\lambda$ respects the completions of $k[P]$ and $k[Q]$. So $\lambda(f_0)$ belongs to $k[Q]$. Recall we have the monoid map $r: P \to M$ which forgets the components in $\bigoplus_{i \in I} \mathbb{N}r_i$. We use the same notation $r: Q \to M$ for the analogous map on $Q$. Then $(\mathfrak{d}, \lambda(f_0))$ becomes a wall over $k[Q]$, and $\lambda(\mathcal{D}_s)$ is a scattering diagram over $k[Q]$.

The consistency of $\lambda(\mathcal{D}_s)$ follows from the consistency of $\mathcal{D}_s$ as $\lambda$ is an algebra homomorphism. $\square$.

We call $\lambda(\mathcal{D}_s)$ the (generalized) cluster scattering diagram of $s$ with special coefficients $\lambda$. In fact, the ordinary cluster scattering diagram $\mathcal{D}_s$ when $r_i = 1$ can be obtained this way. We denote the ordinary one by $\mathcal{D}_s^{ord}$. Its incoming walls are

$$(e^+_1, 1 + p_{i,j}z^{\omega(-d_i, e_i)}).$$

If there exist coefficients $\lambda_{i,j} \in k^*$ such that

$$\prod_{j=1}^{r_i} (1 + \lambda_{i,j}t_i z^{w_i}) = 1 + t_i^{r_i} z^{r_i w_i} = 1 + t_i^{r_i} z^{\omega(-d_i, e_i)},$$

then we can apply the corresponding morphism $\lambda: k[P] \to k[Q]$ to $\mathcal{D}_s$ so that

$$\lambda(\mathcal{D}_s) \cong \mathcal{D}_s^{ord}$$

as they have the exact same set of incoming walls. Here $t_i^{r_i}$ is identified with $p_i$. The existence of such an evaluation $\lambda$ amounts to find the $r_i$ roots of the polynomial $1 + x^{r_i}$ in $k$, which is always possible if $k$ is algebraically closed.

6.5. **Examples.** We illustrate some examples of generalized cluster scattering diagrams in this section.

**Example 6.21.** Consider the fixed data $\Gamma$ consisting of

- the lattice $N = \mathbb{Z}^2$ with with the standard basis $e_1 = (1, 0)$ and $e_2 = (0, 1)$, and the skew-symmetric form $\omega$ be determined by $\omega(e_1, e_2) = -1$;
- $N_{\text{aff}} = N$;
- the rank $r = 2$ and $I = I_{\text{aff}} = \{1, 2\}$;
- positive integers $d_1 = 1$ and $d_2 = 2$;
- the sublattice $N^0$ generated by $e_1$ and $2e_2$;
\[ M = \text{Hom}(N, \mathbb{Z}), \ M^\circ = \text{Hom}(N^\circ, \mathbb{Z}); \]

Let \( s \) be a seed consisting of \( e = (e_1, e_2) \) and \( p_1 = (t_{11}), \ p_2 = (t_{21}, t_{22}). \) We have matrices
\[
B = \begin{pmatrix} 0 & -2 \\ 1 & 0 \end{pmatrix} \quad \text{and} \quad \beta = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}.
\]

In this case we have \( \bar{e}_i = d_i e_i/r_i = e_i. \) So \( \overline{N} = N \) and we shall not worry about the rescaling issue. Then \( w_1 = e_2^2 \) and \( w_2 = -e_1^2. \) We write \( A_i = z^{e_i^*} \) for \( i = 1, 2. \) The coefficients group is \( \mathbb{P} = \mathbb{Z}^3 \) with generators \( \{t_{11}, t_{21}, t_{22}\}. \) The initial incoming scattering diagram is
\[
\mathcal{D}_{s,\text{in}} = \{ (e_1^*, 1 + t_{11} A_2), (e_2^*, (1 + t_{21} A_1^{-1}))(1 + t_{22} A_1^{-1}) \}.
\]

The resulting generalized cluster scattering diagram is
\[
\mathcal{D}_s = \mathcal{D}_{s,\text{in}} \cup \{ (\mathbb{R}_{>0}(1, -1), f_{(1,-1)}), (\mathbb{R}_{>0}(2, -1), f_{(2,-1)}) \}
\]
where
\[
f_{(1,-1)} = (1 + t_{11} t_{21} A_1^{-1} A_2) (1 + t_{11} t_{22} A_1^{-1} A_2) \quad \text{and} \quad f_{(2,-1)} = 1 + t_{11} t_{21} t_{22} A_1^{-2} A_2.
\]

The scattering diagram \( \mathcal{D}_s \) is depicted in Figure 1.

![Figure 1](image)

**Example 6.22.** Consider the fixed data \( \Gamma \) consisting of
- the lattice \( N = \mathbb{Z}^2 \) with with the standard basis \( e_1 = (1, 0) \) and \( e_2 = (0, 1), \) and the skew-
symmetric form \( \omega \) be determined by \( \omega(e_1, e_2) = -1; \)
- \( N_{\text{af}} = N; \)
- the rank \( r = 2 \) and \( I = I_{\text{af}} = \{1, 2\}; \)
- positive integers \( \lambda_1 = 1 \) and \( \lambda_2 = 1; \)
- the sublattice \( N^\circ \) generated by \( e_1 \) and \( e_2; \)
- \( M = \text{Hom}(N, \mathbb{Z}), \ M^\circ = \text{Hom}(N^\circ, \mathbb{Z}); \)

The seed is given by \( e = (e_1, e_2) \) and \( p_1 = (s_1, s_2), \ p_2 = (t_1, t_2). \) The corresponding \( \mathcal{D}_s \) is depicted in Figure 2. We write \( X = z^{e_1^*} \) and \( Y = z^{e_1^*}. \) The five rays depicted in the fourth quadrant are in the directions \((2, -1), (3, -2), (1, -1), (2, -3)\) and \((1, -2)\) in clockwise order. In fact, in the
fourth quadrant there are additional non-trivial walls whose underlying cones are \( \mathbb{R}_{\geq 0} (n, -(n+1)) \) and \( \mathbb{R}_{\geq 0} (n+1, -n) \) for each positive integer \( n \geq 3 \) (which we omit in the figure below). The wall-crossing function, for example for \( \mathbb{R}_{\geq 0} (2k, -(2k+1)) \) for \( k \in \mathbb{Z}_{>0} \), is

\[
f_{\mathbb{R}_{\geq 0} (2k, -(2k+1))} = (1 + s_1^{k+1} s_2^{k+1} t_1^{2k+1} t_2^{2k+1} X^{2k+1} Y^{2k} ) \left( 1 + s_1^{k+1} s_2^{k+1} t_1^{2k+1} t_2^{2k+1} X^{2k+1} Y^{2k} \right),
\]

which can be obtained using Theorem 7.10.

The wall-crossing function attached to the ray \( \mathbb{R}_{\geq 0} (1, -1) \)

\[
f_{\mathbb{R}_{\geq 0} (1, -1)} = \frac{(1 + s_1 t_1 X Y)(1 + s_2 t_2 Y)(1 + s_2 t_2 X Y)(1 + s_2 t_2 Y)}{(1 - s_1 s_2 t_1 t_2 X Y^2)^4}
\]

is much more difficult to calculate. This was explicitly obtained by Reineke and Weist [RW13] by relating the wall-crossing functions to quiver representations.

**Figure 2**

### 6.6. Mutation invariance of \( D_\mu \). A first step to investigate the structure of \( D_\mu \) is through a comparison with \( D_{\mu(s)} \). For the ordinary case, this is called the mutation invariance in [GHKK18]. In the generalized situation, we show an analogous mutation invariance still holds. One just needs to take care of the generalized coefficients \( p_{i,j} \).

Notice that the definition of \( D_\mu \) does not involve the semifield structure of \( P \). So one can view that the coefficients part \( \mathbf{p} \) actually provides a \( \mathbb{Z} \)-basis of the mutiplicative abelian group \( P \) (grouped and labeled in a certain way). Thus even though \( \mu_k(s) \) no longer has principal coefficients in \( P \), \( D_{\mu_k(s)} \) is still defined. To stress that the coefficients are no longer semifield elements, we use \( t_{i,j} \) instead of \( p_{i,j} \).

Now \( s = (e, t) \) consists of \( e \) a labeled basis of \( N \) and tuples of coefficients \( t = (t_{i,j}) \).

**Definition 6.23.** Define the mutation \( \mu_k^+(s) = (e', t') \) such that \( e' = \mu_k(e) \) as before and for the coefficients,

\[
t'_{i,j} = \begin{cases} t_{i,j}^{-1} & \text{ if } i = k \\ t_{i,j} \cdot \prod_{l=1}^{r} t_{l,j}^{[b_{l,i}]} & \text{ if } i \neq k.\end{cases}
\]

**Remark 6.24.** Note that this mutation does not depend on any semifield structure on \( P \). So it is different from the \( \mu_k \) from Definition 4.3 for mutations of many steps. For this reason, we call \( s = (e, p) \) a seed with coefficients (avoiding the type \( A \)- or \( X \)-) and use the new symbol \( \mu_k^+ \) for mutations in this context (as we will see in Section 7.1 the meaning of the sign \( + \)).
We define the scattering diagram $w$ and $T$ viewed as associated to the toric model $U_t$. Theorem 6.27 (or canonical scattering diagram) \[
\text{Definition 6.25. We set } \mathcal{H}_{k,+} := \{m \in \mathbb{M} \mid \langle e_k, m \rangle \geq 0\}, \quad \mathcal{H}_{k,-} := \{m \in \mathbb{M} \mid \langle e_k, m \rangle \leq 0\}.
\]
For $k \in I$, define the piecewise linear transformation $T_k : \mathbb{M} \to \mathbb{M}$ by
\[
T_k(m) := \begin{cases} m + \langle e_k, m \rangle r_k w_k, & m \in \mathcal{H}_{k,+} \\ m, & m \in \mathcal{H}_{k,-}. \end{cases}
\]
One sees that in the two half spaces, the map $T_k$ is actually the restriction of two linear maps $T_{k,+}$ and $T_{k,-}$ respectively. The map $T_k$ is with respect to the seed $s$ and thus sometimes will be denoted as $T_k^s$. The vector $r_k w_k$ can also be expressed as $r_k w_k = \omega(-, d_k e_k) = \sum_{i=1}^n b_i e_i^\ast$. One checks that
\[
T_{k,+}(w_i) = w_i + \beta_k r_k w_k.
\]
Recall we have the projection $r : M \oplus \mathbb{P} \to M$. The transformation $T_k$ can be lifted to $M \oplus \mathbb{P}$ by
\[
\tilde{T}_k(m, p) := \begin{cases} m + \langle e_k, m \rangle r_k w_k, \quad p \cdot t_k^{(e_k, m)}, & m \in \mathcal{H}_{k,+} \\ (m, p), & m \in \mathcal{H}_{k,-}, \end{cases}
\]
where $t_k = \prod_{i=1}^r t_i$. Note that $\tilde{T}_k$ on its domain of linearity is the restriction of two linear transformations $\tilde{T}_{k,+}$ respectively.

**Construction 6.26.** We define the scattering diagram $T_k(\mathfrak{D}_a)$ as in [GHKK18, Definition 1.22] (but taking care of the parameters $t_{i,j}$ here) in the following steps.

1. Replace each wall in $\mathfrak{D}_a$ not fully contained in $e_k^\ast$ if necessary by splitting it into two new walls $(\emptyset \cap \mathcal{H}_{k,+}, f_0)$ and $(\emptyset \cap \mathcal{H}_{k,-}, f_0)$.

Regard this new collection of walls as the current representative of $\mathfrak{D}_a$.

2. For a wall $(\emptyset, f_0)$ contained in $\mathcal{H}_{k,\varepsilon}$, define the wall $T_{k,\varepsilon}(\emptyset, f_0) = (T_{k,\varepsilon}(\emptyset), \tilde{T}_{k,\varepsilon}(f_0))$ where the new wall-crossing function $\tilde{T}_{k,\varepsilon}(f_0)$ is the one obtained from $f_0$ by replacing each monomial of the form
\[
pz m \quad \text{by} \quad \tilde{T}_{k,\varepsilon}(pz^m),
\]
where the later is the monomial corresponding to $\tilde{T}_{k,\varepsilon}(m, p) \in M \oplus \mathbb{P}$. For example, we have
\[
\tilde{T}_{k,+}(t_{i,j} z^{w_i}) = t_{i,j}^{\beta_k} z^{w_i} + \beta_k r_k w_k, \quad \text{while} \quad \tilde{T}_{k,-}(t_{i,j} z^{w_i}) = t_{i,j} z^{w_i}.
\]
We call these walls uniformly by $T_k(\emptyset, f_0)$ no matter which half they belong to. We stress that the sign $\varepsilon$ in $T_{k,\varepsilon}$ is determined by which half space the wall $\emptyset$ lies in.

3. Consider the collection of walls $T_k(\mathfrak{D}_a) := \left\{ T_k(\emptyset, f_0) \mid (\emptyset, f_0) \in \mathfrak{D}(s) \setminus \left( e_k^\ast \prod_{j=1}^{r_k} (1 + t_{k,j} z^{w_k}) \right) \right\} \cup \left\{ \left( e_k^\ast \prod_{j=1}^{r_k} (1 + t_{k,j}^{-1} z^{-w_k}) \right) \right\}$.

Denote the monoid $(P')^\oplus := P_\mu^\oplus(\mathfrak{D}_a) \subset M \oplus \mathbb{P}$. While $\mathfrak{D}_a$ is over $k[\hat{P}_s^\oplus]$, $\mathfrak{D}_\mu^\ast(\mathfrak{D}_a)$ is over $k[(P')^\oplus]$.

**Theorem 6.27** (cf. [GHKK18, Theorem 1.24]). The set of walls $T_k(\mathfrak{D}_a)$ is indeed a consistent scattering diagram over $k[(P')^\oplus]$, and furthermore is equivalent to $\mathfrak{D}_\mu(\mathfrak{D}_a)$.

We find it most natural to understand the mutation invariance by making connection to the canonical wall structure (or canonical scattering diagram) [GS22] via [AG22, Theorem 6.1], where $\mathfrak{D}_a$ can be viewed as associated to the toric model $U_{\Omega(s,\lambda)}$ for general $\lambda$. However, as in Section 5.3.2, this would require the condition
\[
r_i = \gcd(b_{ij}, i \in I).
\]
Fortunately, we can prove the mutation invariance following the same strategy in [GHKK18] without this condition. The proof occupies the rest of the section.

First define a monoid $\tilde{P}$ containing both $P^\oplus$ and $(P')^\oplus$. Let $\sigma$ be the cone in $(M \oplus P)_{\mathbb{R}}$ generated by $\{(w_i, t_{i,j}) \mid i \in I, j \in [1, r_i]\} \cup \{(-w_k, -t_{k,j}) \mid 1 \leq j \leq r_k\}$. Take $\tilde{P} = \sigma \cap (M \oplus P)$ and we tend to talk about scattering diagrams over $k[\tilde{P}]$. However the ideal $m_P$ misses the elements $(w_k, t_{k,j})$. This means a wall such as

$$(e_k^\perp, (1 + t_{k,j}z^{w_k}))$$

in $D_s$ does not qualify as a wall over $k[\tilde{P}]$. For this reason, we extend the definition of scattering diagram as in [GHKK18, Definition 1.27] (slightly generalizing the slab for our needs).

Define

$$N_s^{\perp, k} := \left\{ \sum_{i \in I} a_i \vec{e}_i \mid a_i \in \mathbb{Z}_{\geq 0} \text{ for } i \neq k, \ a_k \in \mathbb{Z}, \text{ and } \sum_{i \in I \setminus \{k\}} a_i > 0 \right\} \subset N.$$

Since $N_s^{\perp, k} = \overline{N}_s^{\perp, k}$, we denote them by $\overline{N}_s^{\perp, k}$.

**Definition 6.28** (cf. [GHKK18, Definition 1.27]). A wall for $\tilde{P}$ is a pair $(d, f_0)$ with $\overline{d}$ as before but with primitive normal vector $n_0$ in $N^{\perp, k}$ and

$$f_0 = 1 + \sum_{k \geq 1, \pi(t) = k n_0} c_{k,t} \cdot tz^{k \omega(-, m_0)} \equiv 1 \mod m_P.$$

The slab for $s$ and $k \in I$ means the pair

$$d_k := \left( e_k^\perp, \prod_{j=1}^{r_k} (1 + t_{k,j}z^{w_k}) \right).$$

A scattering diagram $D$ for $\tilde{P}$ is a collection of walls and possibly this single slab, with the condition that for each $k > 0$, $f_0 \equiv 1 \mod m_P$ for all but finitely many walls in $D$.

We quote the following very hard theorem from [GHKK18]. The objects here are understood in our definitions so there are minor differences. However, one can still prove the theorem in the exact same way. So we omit its proof here.

**Theorem 6.29** ([GHKK18, Theorem 1.28]). There exists a unique (up to equivalence) consistent scattering diagram $\overline{D}_s$ in the sense of Definition 6.28 such that

1. $\overline{D}_s \supset D_{s,in}$,
2. $\overline{D}_s \setminus D_{s,in}$ consists only of outgoing walls.

Furthermore, $\overline{D}_s$ is also a scattering diagram for the $\overline{N}_s^{\perp}$-graded Lie algebra $\mathfrak{g}_s$. As such, it is equivalent to $D_s$.

**Proof of Theorem 6.27.** First we choose a representative for $D_s$ given by Theorem 6.29. Now $T_k(D_s)$ becomes a scattering diagram in the sense of Definition 6.28 for the seed $s' = \mu_k^s(s)$. This is because that

1. the operation $T_k$ removes the old slab $d_k$ and adds the new slab $d_k' := \left( e_k^\perp, \prod_{j=1}^{r_k} (1 + t_{k,j}^{-1}z^{w_k}) \right)$;
2. for a wall (contained in either $H_{k,+}$ or $H_{k,-}$), $T_k$ sends a monomial of the form $\prod_{i,j} (t_{i,j}z^{w_i})^{a_{i,j}}$ in its wall-crossing function to $\prod_{i,j} \left( t_{i,j}^{\beta_{k,i}z^{w_i}}t_k^{\beta_{k,j}z^{w_j}+\beta_{k,r}w_k} \right)^{a_{i,j}}$ or $\prod_{i,j} (t_{i,j}z^{w_i})^{a_{i,j}}$.
So if \( tz^m \in m_p^1 \) for some \( i \), so is \( \tilde{T}_k(tz^m) \).

We next show that (1) \( \tilde{T}_k(\mathcal{D}_s) \) and \( \mathcal{D}_{s'} \) have the same set of slabs and incoming walls; (2) \( \tilde{T}_k(\mathcal{D}_s) \) is consistent as a scattering diagram with a slab. Then by the uniqueness statement of Theorem 6.29, \( \tilde{T}_k(\mathcal{D}_s) \) and \( \mathcal{D}_{s'} \) are equivalent.

The statement (1) follows from the same argument in Step I of [GHKK18, Proof of Theorem 1.24].

For (2), we check the consistency of \( \tilde{T}_k(\mathcal{D}_s) \), that is, for any loop \( \gamma \), \( p_{\gamma, T_k(\mathcal{D}_s)} = \text{id} \) whenever it is defined.

If \( \gamma \) is confined in one of the half spaces, the path-ordered product is identity because of the consistency of \( \mathcal{D}_s \). So we assume that \( \gamma \) crosses the slab \( \mathcal{D}_s' \). Split \( \gamma \) into four subpaths \( \gamma_1, \gamma_2, \gamma_3 \) and \( \gamma_4 \) such that

1. \( \gamma_1 \) starts at a point in \( \mathcal{H}_{k,-} \) and only crosses the slab \( \mathcal{D}_s' \);
2. \( \gamma_2 \) is contained entirely in \( \mathcal{H}_{k,+} \);
3. \( \gamma_3 \) only crosses \( \mathcal{D}_s' \) back to \( \mathcal{H}_{k,-} \);
4. \( \gamma_4 \) is contained entirely in \( \mathcal{H}_{k,-} \).

Let \( \tilde{T}_{k,+} : k[M \oplus \mathcal{P}] \rightarrow k[M \oplus \mathcal{P}] \) be the algebra automorphism induced by \( \tilde{T}_{k,+} \) (see (2) in the Construction 6.26 the action of \( \tilde{T}_{k,+} \) on monomials). Denote by \( p_{\mathcal{D}}' \) the wall-crossing automorphism

\[
\gamma \mapsto \gamma (T^{-1})' \rightarrow \gamma (T^{-1}) (m, m_0) \rightarrow (T(z^m))^{(m_0)} (T^{-1}(m_0)) \rightarrow z^m f(\tilde{T}(z^m)).
\]

Note that the wall \( \mathcal{D} \) gets transformed under \( \tilde{T}_k \) to be contained in \( (T^{-1})'(n_0) \) with \( f(\tilde{T}(z^m)) \). So the above action is the same as \( p_{\gamma, T_k(\mathcal{D}_s)}(z^m) \).

To show \( p_{\gamma, T_k(\mathcal{D}_s)} = \text{id} \), it suffices to show that

\[
(6.5) \quad \tilde{T}_{k,+}^{-1} \circ p_{\mathcal{D}}' = p_{\mathcal{D}}.
\]

so that \( p_{\gamma, T_k(\mathcal{D}_s)} = p_{\gamma, T_k(\mathcal{D}_s)} = \text{id} \).

Let the left-hand side act on some monomial, we have

\[
\tilde{T}_{k,+}^{-1} \circ p_{\mathcal{D}}'(tz^m) = \tilde{T}_{k,+}^{-1} \left( tz^m \prod_{j=1}^{r_k} (1 + t_{k,j}^{-1} z^{-w_k} \gamma_{k,m}) \right)
\]

\[
= t \cdot t_{k}^{-\gamma_{k,m}} \cdot z^{m-\gamma_{k,m}} \prod_{j=1}^{r_k} (1 + t_{k,j}^{-1} z^{-w_k} \gamma_{k,m})
\]

\[
= t z^m \prod_{j=1}^{r_k} (1 + t_{k,j}^{-1} z^{-w_k} \gamma_{k,m})
\]

\[
= p_{\mathcal{D}}(tz^m).
\]
This finishes the proof.

Example 6.30. In this example we compute $T_2(\mathcal{D}_s)$ for the scattering diagram $\mathcal{D}_s$ in Example 6.21. Recall that the exchange matrix for $s$ is $B = (0 \ 1\ -2)$. So we have $T_2,+(e_2^3) = e_2^3 - 2e_1^1$, which determines the ray $\mathbb{R}_{\geq 0}(e_2^3 - 2e_1^1)$ of the diagram below.

$\begin{align*}
1 + t_{11}t_{21}t_{22}A_1^{-2}A_2 \\
(1 + t_{21}^{-1}A_1)(1 + t_{22}^{-1}A_1) \\
1 + t_{11}A_2
\end{align*}$

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure3}
\caption{}
\end{figure}

6.7. Positivity. The scattering diagram $\mathcal{D}_s$ has the following positivity.

Theorem 6.31 (cf. [GHKK18, Theorem 1.28]). The scattering diagram $\mathcal{D}_s$ is equivalent to a scattering diagram all of whose walls $(d, f_s)$ satisfy $f_s = (1 + tz^m)c$ for some $m = \omega(-, \tilde{n}), n \in \mathbb{N}^+$, some $t \in \mathbb{P}$ such that $\pi(t) = n$, and $c$ being a positive integer. In other words, if we write $n = \sum_{i \in I} \alpha_i e_i$, then

1. $d$ is contained in $\tilde{n}^+ \subset M_\mathbb{R}$ where $\tilde{n} = \sum_{i \in I} \alpha_i \frac{\omega}{m} \epsilon_i$;
2. $m = \sum_{i \in I} \alpha_i w_i = \omega(-, \tilde{n})$;
3. if writing $t = \prod_{i,j} t_{i,j}^{\alpha_{i,j}}$, then $\sum_{j=1}^{r} \alpha_{i,j} = \alpha_i$.

Proof. This theorem essentially follows from [GHKK18, Appendix C.3], the proof of the positivity of $\mathcal{D}_s^{GHKK}$. We use a representative of $\mathcal{D}_s$ constructed in the same algorithm used to produce $\mathcal{D}_s^{GHKK}$ in the proof of [GHKK18, Theorem 1.28]. We will construct order by order a sequence of finite scattering diagrams $\mathcal{D}_1 \subset \mathcal{D}_2 \subset \cdots$ (over $k[P_\mathbb{R}]$ or the graded Lie algebra $g_\mathbb{R}$) such that their union

$\mathcal{D} = \bigcup_{k=1}^{\infty} \mathcal{D}_k$

is equivalent to $\mathcal{D}_s$. We then prove inductively that every wall in $\mathcal{D}_k$ has the positivity property.

Let $\mathcal{D}_1 = \mathcal{D}_{s,n}$. Note that $\mathcal{D}_1$ is equivalent to $\mathcal{D}_s$ modulo $(P^+)^2$. Suppose that we have defined up to $\mathcal{D}_k$ which is equivalent to $\mathcal{D}$ modulo $(P^+)^{k+1}$, and assume that every wall in $\mathcal{D}_k$ has wall-crossing function of the form $(1 + tz^m)c$ for some positive integer $c$. We construct $\mathcal{D}_{k+1}$ as follows, and show that it is equivalent to $\mathcal{D}$ modulo $(P^+)^{k+2}$ and furthermore that it still has the same positivity property for its wall-crossing functions.

There is a finite rational polyhedral cone complex that underlies the support of $\mathcal{D}_k$ (which is true for any scattering diagram with finitely many walls). We call the codimension two cells joints. Let $j$ be a joint of $\mathcal{D}_k$. Then by [GHKK18, Definition-Lemma C.2], it falls into two classes

1. parallel, if every wall with the normal vector $n$ containing $j$ has $\omega(-, n)$ tangent to $j$;
2. perpendicular, if every wall with the normal vector $n$ containing $j$ has $\omega(-, n)$ not tangent to $j$. 

42
Let $\gamma_i$ be a simple loop around $j$ small enough so that it only intersects walls containing $j$. By our assumption, the path-ordered product $p_{\gamma_i, D_k}$ is identity modulo $(P^+)^{k+1}$, but modulo $(P^+)^{k+2}$, it can be written as

$$p_{\gamma_i, D_k} = \exp \left( \sum_{d(t,m) = k+1} c_{t,m} t z^m \partial u(t,m) \right),$$

where $c_{t,m} \in k$. Here we define the degree $d(t,m) := k + 1$ if $(t,m) \in (P^+)^{k+1} \setminus (P^+)^{k+2}$, and $n(t,m)$ is primitive in $N^+$ uniquely determined by $(t,m)$.

If $j$ is perpendicular, we define a set of walls

$$\mathfrak{D}[j] := \{(i - R \geq 0 m, (1 + t z^m)^{\pm c_{t,m}}) \mid d(t,m) = k + 1\},$$

where $i - R \geq 0 m$ is of codimension one since $m$ is not tangent to $j$. Here the function $(1 + t z^m)^{\pm c_{t,m}}$ makes sense as a power series. The sign $\pm$ in the power is chosen so that when $\gamma_i$ crosses $i - R \geq 0 m$, the wall-crossing automorphism is

$$\exp(-c_{t,m} t z^m \partial u(t,m)).$$

In this way, if we add the walls in $\mathfrak{D}[j]$ to $\mathfrak{D}_k$, we have the path-ordered product $p_{\gamma_i, \mathfrak{D}_k \cup \mathfrak{D}[j]} = \text{id}$ modulo $(P^+)^{k+2}$. We then define

$$\mathfrak{D}_{k+1} = \mathfrak{D}_k \cup \bigcup_j \mathfrak{D}[j],$$

where the union is over all perpendicular joints of $\mathfrak{D}_k$.

There are two things we need to show in the induction:

1. $\mathfrak{D}_{k+1}$ is equivalent to $\mathfrak{D}_k$ modulo $(P^+)^{k+2}$.
2. All the walls in $\mathfrak{D}_{k+1}$ have wall-crossing functions of the form $(1 + t z^m)^c$ for some positive integer $c$.

Part (1) follows from the argument in [GHKK18, Lemma C.6 and Lemma C.7]. This part guarantees that the constructed union $\mathfrak{D}$ is equivalent to $\mathfrak{D}_s$.

Part (2) is about the positivity of wall-crossings. By the construction of $\mathfrak{D}_{k+1}$, we only need to examine the new walls emerging from perpendicular joints of $\mathfrak{D}_k$. Let $j$ be a perpendicular joint of $\mathfrak{D}_k$. The integral normal space $j^\perp \cap N$ is a rank two saturated sublattice $O$ of $N$. Locally at $j$, $\mathfrak{D}_k \cup \mathfrak{D}[j]$ induces a scattering diagram living in $O^\vee_R = M_R / (\Lambda_j \otimes R)$. Precisely, consider the set of walls

$$\mathfrak{D}' = \{((v + \Lambda_j \otimes R)/(\Lambda_j \otimes R), f_\partial) \mid j \subset \partial, (\partial, f_\partial) \in \mathfrak{D}_k \cup \mathfrak{D}[j]\}.$$

The wall-crossing functions $f_\partial$ are all of the form

$$(1 + t z^m)^c,$$

c \in k (f_\partial$ makes sense as a power series). The wall $\partial$ has some primitive normal vector $o \in O \cap N^+$, and $m$ is proportional to $\omega(-, o)$. We also know since $j$ is perpendicular, $\bar{m} \neq 0$ (the image of $m$ under the quotient $M \rightarrow O^\vee$) in $O^\vee_R$. And the one dimensional wall $\partial = (\partial + \Lambda_j \otimes R) / (\Lambda_j \otimes R)$ is contained in $R(\bar{m})$, orthogonal to the normal vector $o$. Then $\mathfrak{D}'$ is a rank two scattering diagram in $O^\vee_R$ over $k[P^+]$, with the monoid map from $P^+$ to $O^\vee$ being $r: P \rightarrow M$ post-composed by the quotient from $M$ to $O^\vee$. It is consistent up to modulo $(P^+)^{k+2}$. Then by [GHKK18, Proposition C.13], the wall-crossing functions admit the positivity property, i.e. the power $c$ is always a positive integer. This shows the positivity for $\mathfrak{D}_{k+1}$ assuming that of $\mathfrak{D}_k$. Therefore, the union $\mathfrak{D}$ is also positive by induction, hence so is $\mathfrak{D}_s$. \qed
7. The cluster complex structure

In this section, we study the cluster complex structure of the scattering diagram $\mathcal{D}_s$, which is a description of parts of the walls of $\mathcal{D}_s$. The construction of such a structure of $\mathcal{D}_s$ is analogous to [GHKK18, Construction 1.30].

7.1. The cluster complex. Take a representative for the scattering diagram $\mathcal{D}_s$ with minimal support (which always exists). By Theorem 6.29, one can choose such a representative $\mathcal{D}_s$ so that there are no other walls contained in the initial incoming ones $\partial_i$.

Define

\[ C^+ = C^+_s := \{ m \in M_R \mid \langle e_i, m \rangle \geq 0 \ \forall i \in I \}, \]
\[ C^- = C^-_s := \{ m \in M_R \mid \langle e_i, m \rangle \leq 0 \ \forall i \in I \}. \]

The closed cones $C^\pm_s$ are closures of connected components of $M_R \setminus \text{Supp}(\mathcal{D}_s)$. They are thus called chambers. By the mutation invariance Theorem 6.27, we have that the cones

\[ T^{-1}_k \left( C^\pm_{\mu_k(s)} \right) \subset M_R \setminus \text{Supp}(\mathcal{D}_s) \]

are also closures of connected components. Applying mutations on seeds provides an iterative way to construct chambers of $M_R \setminus \text{Supp}(\mathcal{D}_s)$ as follows.

Note again that the coefficients part of $s = (e, t)$ does not mutate as in Definition 4.3, which requires setting the tropical semifield $\mathbb{P}$ from the initial seed and once for all. Instead, we regard the coefficients part $t$ as in the multiplicative group $\mathbb{P}$ and mutates in the way specified by Section 6.6. In this way, we can apply mutations iteratively on $s$.

Let us consider the rooted tree $\mathcal{T}_s$ from Definition 4.6. There is an association $v \mapsto s_v$ such that $v_0 \mapsto s$ and adjacent seeds with coefficients are related by the corresponding mutation (in the sense of Section 6.6) of the labeled edges. Once this association is done, we denote the rooted tree by $\mathcal{T}_s$.

Suppose the unique path from $v_0$ to a vertex $v$ goes through the arrows labeled by $\{k_1, k_2, \ldots, k_l\}$. Define the piecewise linear map

\[ T_{v_0, v} = T_{k_l} \circ \cdots \circ T_{k_2} \circ T_{k_1} : M_R \to M_R. \]

Since $C^\pm_s$ are chambers of the scattering diagram $\mathcal{D}_s$, then again due to the mutation invariance, we have that

\[ C^\pm_v := T_{v_0, v}^{-1} \left( C^\pm_{s_v} \right) \]

are chambers of $\mathcal{D}_s$.

Each $C^\pm_v$ is a simplicial (rational polyhedral) cone of maximal dimension, as each $T_k$ is a linear isomorphism on its domains of linearity. The intersection $C^+_s \cap C^+_\mu_k(s)$ is their common facet generated by $\{e_i^+ \mid i \neq k\}$. Each facet of $C_v$ is canonically labeled by an index $i \in I$. Inductively, for any two vertices $v$ and $v'$ connected by an arrow labeled by $k \in I$, then $C^+_v$ and $C^+_v$ share a common facet labeled by $k$.

We borrow the following notation from [GHKK18]: we use the short-hand subscription notation $v \in s$ for an object parametrized by a vertex $v \in \mathcal{T}_s$ with the root $v_0$ labeled by $s$. This is done to emphasize the dependence on the initial seed $s$.

**Definition 7.1.** We denote by $C^\pm_{v \in s}$ the chambers $C^\pm_v$ of $\subset M_R \setminus \text{Supp}(\mathcal{D}_s)$. We write $\Delta^\pm_v$ for the set of chambers $C^\pm_{v \in s}$ for $v$ running over all vertices of $\mathcal{T}_s$. We call elements in $\Delta^\pm_v$ cluster chambers.

**Remark 7.2.** As we have pointed out, $C^+_v \cap C^+_v$ is a common facet if $v$ and $v'$ are adjacent in $\mathcal{T}_s$. More generally, by adding all the faces of every $C^+_v$ to the set $\Delta^+_v$, we obtain a collection of cones which form
a cone complex, still denoted by $\Delta_s^\pm$. For this reason, we call $\Delta_s^+$ the cluster (cone) complex and $\Delta_s^-$ the negative cluster (cone) complex.

The simplicial cone $C_{v \in \mathfrak{s}}^+$ is determined by (the generators of) its one-dimensional faces. The cone $C_{v \in \mathfrak{s}}^-$ is generated by the dual vectors $\{e_i^* | i \in I\}$. These are pulled back by $T_{v \in \mathfrak{s}}^{-1}$ to be the generators of $C_{v \in \mathfrak{s}}^-$.  

**Definition 7.3.** We define the $g$-vectors for $v \in \Sigma$ as a tuple

$$g_v = (g_{i,v} | i \in I),$$

where $g_{i,v} := T_{v \in \mathfrak{s}}^{-1}(e_i^*) \in M$. We will use the notation $g_{v \in \mathfrak{s}}$ to emphasize the initial seed $s$.

**Remark 7.4.** Denote the dual vectors (in $N$) of $g_v$ by $g_v^* = (g_{i,v}^* | i \in I)$. They are normal vectors of the facets of $C_{v \in \mathfrak{s}}^+$. Since the walls of $\mathfrak{D}_s$ only have normal vectors in $N_s^+$ or $-N_s^+$, the vector $g_v^*$ has a well-defined sign

$$\varepsilon_{i,v} = \text{sgn}(g_{i,v}^*) = \begin{cases} + & \text{if } g_{i,v}^* \in N_s^+ \\ - & \text{if } g_{i,v}^* \in N_s^- \end{cases}.$$

We will show later the vectors $g_v$ can be calculated iteratively by a variant of mutations as defined below.

**Definition 7.5.** Let $e = (e_i | i \in I)$ be a seed (without coefficients) for $\Gamma$. Define the signed mutation $\mu_k^\varepsilon(e) = (e_i' | i \in I)$ for $\varepsilon \in \pm$ as follows.

$$e_i' = \begin{cases} -e_k, & \text{if } i = k \\ e_i + [-\varepsilon \omega(e_i, d_k e_k)]_+ e_k, & \text{if } i \neq k. \end{cases}$$

So the signed mutation $\mu_k^+ \varepsilon$ coincides with our previous Definition 6.23 (ignoring the coefficients part).

On the mutation of the dual of $e$, we use the same notation $\mu_k^\varepsilon(e^*) = (f_i' | i \in I)$ where $e^* = (f_i | i \in I)$. Then

$$f_i' = \begin{cases} f_i, & \text{if } i \neq k \\ -f_k + \sum_{i \in I} [-\varepsilon \omega(e_i, d_k e_k)]_+ f_k, & \text{if } i = k. \end{cases}$$

There is another tuple of vectors in $M$ that changes under signed mutations. For a seed $s$, let $w = (w_i | i \in I)$ where

$$w_i := \omega(-\frac{d_k e_k}{rk}) = \sum_{j \in I} b_{ji} f_i \in M.$$

Let $w' = (w'_i)$ associated to $\mu_k^\varepsilon(e)$. Then we have

$$w'_i = \begin{cases} -w_k, & \text{if } i = k \\ w_i + [\varepsilon \omega(e_k, d_k e_i)]_+ w_k, & \text{if } i \neq k. \end{cases}$$

We will later denote $\mu_k^\varepsilon(w) = w'$.

There are also signed mutations for coefficients. Recall we have fixed a multiplicative abelian group $\mathbb{P} = \prod_{i \in I} \mathbb{Z}^{r_i}$. The coefficients $t = (t_{i,j} | i \in I, j \in [1, r_i])$ are a basis of $\mathbb{P}$.

**Definition 7.6.** For $s = (e, t)$, a seed $e$ together with coefficients $t = (t_{i,j})$ in $\mathbb{P}$, we define its signed mutation in direction $k$, $\mu_k^\varepsilon(e, (t_{i,j})) = (e', (t'_{i,j}))$ for $\varepsilon \in \pm$ by setting $s' = \mu_k^\varepsilon(s)$ and

$$t'_{i,j} = \begin{cases} t_{i,j}^{-1} & \text{if } i = k \\ t_{i,j} \cdot \prod_{l=1}^{r_i} t_{k,l}^{[\varepsilon \omega(e_k, e_i)]_+} & \text{if } i \neq k. \end{cases}$$
Proposition 7.7 (cf. [Mou20, Proposition 4.4.9]). For every \( v \in \mathcal{I}_s \), the dual of \( g \)-vectors \( g^*_v \) is a seed of \( N \). These seeds and their duals, i.e. the \( g \)-vectors, can obtained iteratively as follows.

1. \( g_{v_0} = e^* \) and \( g^*_{v_0} = e \);
2. for any \( v \rightarrow v' \) in \( \mathcal{I}_s \), we have

\[
g^*_{v'} = \mu^\varepsilon_k (g^*_v), \quad g_{v'} = \mu^\varepsilon_k (g_v).
\]

Proof. We prove this proposition by induction on the distance from \( v \) to \( v_0 \). The base case is when \( v = v_0 \), in which we have

\[
g^*_{v} = \mu^1_k (e) = \mu^1_k (g^*_{v_0}), \quad g_{v} = \mu^1_k (e^*) = \mu^1_k (g_{v_0}).
\]

Now assuming that \( v \neq v_0 \) and suppose that the unique path from \( v_0 \) to \( v \) starts with \( v_0 \rightarrow i \rightarrow v_1 \) for some \( i \in I \). Write \( s_1 = s_{v_1} = \mu^i_4 (s) \). By induction, we assume that the proposition holds for \( g \)-vectors with respect to the seed \( s_1 \):

\[
g^*_{v' \in s_1} = \mu^\varepsilon_k (g_{v' \in s_1})
\]

where \( \varepsilon = \varepsilon_{k,v \in s_1} = \text{sgn}(g^*_{k,v \in s_1}) \) with respect to \( s_1 \). Note that by definition

\[
g^*_{\overline{s}_1} = (T^s_1)^{-1}(g^*_{v' \in s_1}), \quad g_{\overline{s}_1} = (T^s_1)^{-1}(g_{v' \in s_1}),
\]

and we want to prove

\[
g^*_{v' \in s} = \mu^i_k (g_{v' \in s})
\]

where \( \delta = \varepsilon_{k,v \in s} \) with respect to \( s \).

Then it amounts to show that

\[
(T^s_1)^{-1} \circ \mu^i_k (g_{v' \in s_1}) = \mu^\delta_k \circ (T^s_1)^{-1}(g_{v' \in s_1}).
\]

We split the discussion in the following two cases. The codimension one skeletons of the chambers \( C^+_{v \in s_1} \) and \( C^+_{v' \in s_1} \) are in the essential support of \( D_{s_1} \). As \( v \) and \( v' \) are adjacent, these two chambers share a common facet. Therefore they are either separated by the hyperplane \( e_i^+ \) or contained in the same half space (since the hyperplane is also in the essential support).

**Case 1.** The two groups of \( g \)-vectors \( g_{v' \in s_1} \) and \( g_{v' \in s_1} \) are separated by \( e_i^+ \). In this case, the normal vector \( g^*_{k,v \in s_1} \) is in the direction of \( e_i \). The signs \( \delta \) and \( \varepsilon \) on the two sides of (7.1) are then different. We assume that \( \varepsilon = \text{sgn}(g^*_{k,v \in s_1}) = + \); the other case is analogous. By our assumption, \( g^*_{v' \in s_1} \) qualifies as a seed of fixed data \( \Gamma \), thus forming a basis of \( N \), which implies \( g^*_{k,v' \in s_1} = e_i \). Since \( \lambda_j g^*_{j,v \in s_1} \mid j \in I \) form a basis of the sublattice \( N^\circ \), we have \( d_i = d_k \). We note that the map \( T^s_1 \) is actually determined by the vectors \( e_i \) and \( d_i e_i \). On the left hand side of (7.1), \( T^s_1 \) is the identity, while on the right hand side, it is \( T^s_1 \). So we need to show the equality

\[
\mu^i_k (g_{v' \in s_1}) = \mu^\varepsilon_k (T^s_1)^{-1}(g_{v' \in s_1}).
\]

To simplify the notation, we denote \( g = g_{v' \in s_1} \) and \( g_j = g_{j,v' \in s_1} \). On the left side of the equality, the tuple \( \mu^i_k (g) = (g'_k) \) differs with \( g \) by only one vector

\[
g'_k = -g_k + \sum_{i \in I} \lfloor -b^j_{ik} \rfloor + g_i.
\]

On the right hand side, we first have

\[
(T^s_1)^{-1}(g_k) = -g_k + \sum_{i \in I} -b^j_{ik} g_i.
\]
while other g-vectors remain unchanged under \((T_{i,+}^s)^{-1}\). It is easy to check that the dual of \((T_{i,+}^s)^{-1}\) is an automorphism of \((N,\omega)\), that is, it is a linear automorphism on \(N\) preserving the form \(\omega\). Thus we have, if writing \(\mu_k \circ (T_{i,+}^s)^{-1}(g_{v\in\Xi}) = (g''_v)\),

\[
g''_v = -g_k + \sum_{i\in I} -b_{ik}^v g_i + \sum_{i\in I} [b_{ik}^v]_\mu g_i = g'_k, \quad \text{and} \quad g''_v = g_i \text{ for } i \neq k.
\]

This finishes the proof of the desired equality.

**Case 2.** The g-vectors \(g_{k,v\in\Xi}\) and \(g'_{k,v\in\Xi}\) are all contained in the same half \(H_{i,+}^s\) or \(H_{i,-}^s\). Again we need to prove (7.1). We observe that the two signs \(\delta \text{ and } \varepsilon\) are equal. In fact, the sign \(\varepsilon\) of \(g_{k,v\in\Xi}\) depends on its coordinates in \(e_{j,v_i}\) for \(j \neq i\) since \(g_{k,v\in\Xi}\) is not purely proportional to \(e_i\). The same is true for the sign \(\delta\) which only depends on \(g_{k,v\in\Xi}\)'s coordinates in \(e_j\) for \(j \neq i\). Since \(g_{k,v\in\Xi}\) only differ in the direction of \(e_i\), and also because \(e_{j,v_i}\) and \(e_j\) also differ by multiples of \(e_i\), we conclude that \(\varepsilon = \delta\).

The equality (7.1) then directly follows from a fact we already mentioned in Case 1 that the dual of \((T_{i,+}^s)^{-1}\) acts as an automorphism on \((N,\omega)\).

A direct corollary of Proposition 7.7 is another description of c-vectors mentioned in Section 3.3. Recall that we have \(\pi : P \to \overline{P} , p_{ij} \to \overline{p}_i\). We write the group operation in \(P\) and \(\overline{P}\) by addition instead of multiplication.

**Corollary 7.8.** We identify the lattice \(\overline{\Xi}\) with \(\overline{P}\) by \(\overline{e}_i = \frac{d_i}{r_i} e_i \mapsto \overline{p}_i\). Then we have for any \(i \in I\) and \(v \in \overline{\Xi}\),

\[
d_i g_{i,v} = \overline{p}_i + v, \quad d_i g_{i,v} = r_i \overline{p}_i + v = \overline{p}_i + v.
\]

**Proof.** For the initial vertex \(v_0\), this is given by the identification \(\overline{e}_i \mapsto \overline{p}_i\). The iteration of \(g_{i,v}^\ast\) is provided by signed mutations according to Proposition 7.7. We have if \(v \xrightarrow{k} v'\) in \(\overline{\Xi}\),

\[
g_{i,v'} = \begin{cases} -g_{i,v}^\ast & \text{if } i = k \\ g_{i,v}^\ast + [-\varepsilon b_{ik}^v]_\mu g_{i,v}^\ast & \text{if } i \neq k. \end{cases}
\]

where \(\varepsilon = \text{sgn}(g_{i,v}^\ast)\). What is implicit is that we have already known that \(g_{i,k}^\ast\) is either non-negative or non-positive. On the other hand, the mutation of \(p_{i,v}\) is given by

\[
p_{i,v'} = \begin{cases} -p_{i,v} & \text{if } i = k \\ p_{i,v} + b_{ik}^v \cdot p_{i,v}^\ast & \text{if } i \neq k \text{ and } b_{ik} \leq 0 \\ p_{i,v} + b_{ik}^v \cdot p_{i,v}^\ast & \text{if } i \neq k \text{ and } b_{ik} > 0. \end{cases}
\]

Thus assuming \(d_i g_{i,v}^\ast = p_{i,v}\) for all \(i \in I\) would imply \(d_i g_{i,v}^\ast = p_{i,v'}\) for all \(i \in I\) as they have the same mutation formula when \(p_{i,k}^\ast\) has a well-defined sign. Therefore the result is proved by induction on the distance from \(v\) to \(v_0\).

**Lemma 7.9.** The generalized coefficients \(p_{i,j,v}\) have the following signed mutation formula. If \(v \xrightarrow{k} v'\) in \(\overline{\Xi}\), then

\[
p_{i,j,v'} = \begin{cases} -p_{k,j,v} & \text{if } i = k \\ p_{i,j,v} + [\varepsilon \beta_{k1}^v]_\mu \cdot \sum_{j=1}^{r_k} p_{k,j,v} & \text{if } i \neq k. \end{cases}
\]

where \(\varepsilon = \text{sgn}(g_{k,v}^\ast)\).

**Proof.** By Corollary 7.8, \(p_{i,v}\) is sign coherent because \(g_{i,v}^\ast\) is so. As we have already shown in Proposition 3.17 that the sign coherence of \(p_{i,v}\) implies that of \(p_{i,j,v}\), the result follows by induction.
7.2. Wall-crossings. We next study the wall-crossing functions attached to walls of the cluster chambers. Each cluster chamber $C^+_v \in \mathfrak{S}$ has exactly $n$ facets $\mathcal{D}_{i,v} \in \mathfrak{S}$ naturally indexed by $I$ (a facet has the same index as its normal vector $g_{i,v} \in \mathbb{R}^n$). The wall $| \mathcal{D}_{i,v} \cap \mathcal{D}_{i',v} |$ is pulled back by $T_{i,v}^{-1}$ from the scattering diagram $\mathcal{D}_a$ (with coefficients $t_i$). The wall-crossing function $f_{i,v}$ has the following description. Here we identify the initial coefficients $t_{i,j}$ with $p_{i,j}$, and endowed $\mathbb{P}$ the semifield structure $\text{Trop}(p)$.

**Theorem 7.10.** The scattering diagram $\mathcal{D}_a$ has a representative in its equivalent class such that it is the union of the scattering diagram

$$\mathcal{D}(\Delta^+_v) := \{(\mathcal{D}_{i,v}, f_{i,v}) | i \in I, v \in \mathfrak{S}_v \} \quad \text{where} \quad f_{i,v} = \prod_{j=1}^n \left( 1 + \frac{\varepsilon_{i,j,v}}{p_{i,j,v}} \cdot \sum_{j=1}^n \frac{\beta_j g_{j,v}}{r_j} \right)$$

and another one whose support is disjoint from $\Delta^+_v$.

**Proof.** We prove this theorem by induction on the distance from $f$ to $C^+_v$ and $f^{-1}$. These two functions are related by the signed mutation $\mu$. We identify the initial coefficients $t_{i,j}$ simply by reversing the monomials in $v_{i,j}$.

Let’s look at the chambers $\tau := C^+_{v_{i\in I}}$, $\tau' := C^+_{v'_{i\in I}}$ in $\mathcal{D}_a$. They have g-vectors satisfying

$$g_{v'_{i\in I}} = \mu^*(g_{v_{i\in I}})$$

where $\varepsilon = \varepsilon_{k,v_{i\in I}} := \text{sgn}(g_{k,v_{i\in I}})$. For the wall-crossing functions, by our assumption, for $i \in I$, we have

$$f_{i,v_{i\in I}} = \prod_{j=1}^n \left( 1 + \frac{\varepsilon_{i,j,v}}{p_{i,j,v}} \cdot \sum_{j=1}^n \frac{\beta_j g_{j,v}}{r_j} \right)$$

and

$$f_{i',v'_{i\in I}} = \prod_{j=1}^n \left( 1 + \frac{\varepsilon_{i,j,v}}{p_{i,j,v}} \cdot \sum_{j=1}^n \frac{\beta_j g_{j,v}}{r_j} \right).$$

These two functions are related by the signed mutation $\mu^*_k$. More precisely, we have

$$\mu^*_k(g_{v'_{i\in I}}, p_{v'_{i\in I}}) = (g_{v'_{i\in I}}^+, p_{v'_{i\in I}}), \quad \mu^*_k(w_{v'_{i\in I}}) = w_{v'_{i\in I}}.$$ 

We want to pull back the chambers $C^+_{v_{i\in I}}$ and $C^+_{v'_{i\in I}}$ as well as the wall-crossing functions $f_{i,v_{i\in I}}$ and $f_{i',v'_{i\in I}}$ to $\mathcal{D}_a$ via the operation $(T^+_a)^{-1}$ to get the chambers $\sigma := C^+_{v_{i\in I}}$, $\sigma' := C^+_{v'_{i\in I}}$ and the wall-crossing functions $f_1 := f_{i,v_{i\in I}}$ and $f'_1 := f_{i',v'_{i\in I}}$ by the mutation invariance Theorem 6.27. We want to show that $f_1$ and $f'_1$ are also related by signed mutations. In the following, we calculate $f_1$ and $f'_1$ in detail by applying $T_{i_0}^{-1}$ to $f_{i,v_{i\in I}}$ and $f_{i',v'_{i\in I}}$. This depends on the following two cases as in the proof of Proposition 7.7:

1. The two chambers $\tau$ and $\tau'$ are separated by the hyperplane $\varepsilon_{i_0}^+$;
2. They are contained in the same half space $H_{i_0,+}$ or $H_{i_0,-}$.

**Case 1.** In this case, the normal vector $g_{i_0,v_{i\in I}}$ is either $\varepsilon_{i_0}$ or $-\varepsilon_{i_0}$. Assume it is $\varepsilon_{i_0}$; the other case is similar. Then the chamber $\tau$ is in $H_{i_0,+}$ while $\tau'$ is in $H_{i_0,-}$. First of all, we have $f_k = f'_k$ obtained simply by reversing the monomials in $f_{k,v_{i\in I}} = f_{k,v'_{i\in I}}$. Since $T_{i_0}$ (as well as $T_{i_0}^{-1}$) is identity on $H_{i_0,+}$, we have for $i \neq k$, $f'_i = f_{i,v_{i\in I}}$. Note that for the signs, for $i \in I$,

$$\varepsilon_{i,v'_{i\in I}} = \varepsilon_{i,v_{i\in I}}$$
unless \( g^*_k v_0 \in S_1 \) is proportional to \( e_{i_0} \), which only happens for \( g^*_k v_0' \in S_1 \), where we have
\[
\varepsilon_{k,v' \in S_1} = - , \quad \varepsilon_{k,v' \in S_1} = + .
\]
So we conclude for any \( i \in I \),
\[
f'_i = \prod_{j=1}^{r_i} \left( 1 + (p_{i,j,v' \in S_1} z^{w_{i,j,v' \in S_1}})^{\varepsilon_{i,j,v' \in S}} \right).
\]

For \( f_{i,v \in S_1} \) and \( f_i \), we first consider the signs \( \varepsilon_{i,v \in S_1} \) and \( \varepsilon_{i,v \in S} \). Since the dual of \( T_{i_0}^{-1} \) on \( N \) only shifts in the direction of \( e_{i_0} \), we have for \( i \neq k \)
\[
\varepsilon_{i,v \in S_1} = \varepsilon_{i,v \in S},
\]
as the vectors \( g^*_i v_0 \in S_1 \) and \( g^*_i \in S \) must have the same sign in all the other directions except for \( e_{i_0} \), and the only one proportional to \( e_{i_0} \) is \( g^*_i v_0 \in S_1 \). Thus we have for \( i \neq k \),
\[
f_i = \prod_{j=1}^{r_i} \left( 1 + \tilde{T}_{i_0}^{-1}(p_{i,j,v \in S_1} z^{w_{i,j,v \in S_1}})^{\varepsilon_{i,j,v \in S}} \right)
\]
We want to show that \( f_i \) and \( f'_i \) are related by the mutation \( \mu_k^\delta \). Precisely, it amounts to show that
\[
\mu_k^\delta \left( \tilde{T}_{i_0}^{-1}(p_{i,j,v \in S_1} z^{w_{i,j,v \in S_1}} | i \in I, j \in [1, r_i]) \right) = \mu_k^\delta \left( p_{i,j,v \in S_1} z^{w_{i,j,v \in S_1}} | i \in I, j \in [1, r_i] \right)
\]
where \( \delta \) is the sign \( \varepsilon_{i,j,v \in S} \). Here we abuse the notation \( \mu_k^\delta \) which acts on a tuple of functions, but it should be clear what it means. By our assumption, \( \varepsilon = + \) and \( \delta = - \varepsilon = - \). Then this follows from the following general fact that for any seed \((e, t)\) and \( k \in I \), we have
\[
\mu_k^\delta \left( \tilde{T}_{i_0}^{-1}(t_{i,j} z^{w_i} | i \in I, j \in [1, r_i]) \right) = \mu_k^\delta \left( t_{i,j} z^{w_i} | i \in I, j \in [1, r_i] \right).
\]

Case 2. Suppose \( \tau \) and \( \tau' \) are both contained in the same half space. According to our above discussion, as in the notation of (7.2), it then amounts to check that
\[
\tilde{T}_{i_0}^{-1}(\mu_k^\delta(p_{i,j,v \in S_1} z^{w_{i,j,v \in S_1}} | i \in I, j \in [1, r_i])) = \mu_k^\delta(\tilde{T}_{i_0}^{-1}(p_{i,j,v \in S_1} z^{w_{i,j,v \in S_1}} | i \in I, j \in [1, r_i]))
\]
where \( \delta = \varepsilon_{i,j,v \in S} \). As we have discussed in the Case 2 of the proof of Proposition 7.7, the signs are equal: \( \delta = \varepsilon \). Then the rest follows immediately from the fact that the dual of \( T_{i_0, \varepsilon} \) acts as an automorphism on the data \((N, \omega)\).

8. RECONSTRUCT \( \mathcal{A}^{\text{Prin}} \)

In this section, we see how to reconstruct the generalized cluster algebra \( \mathcal{A}^{\text{Prin}}(s) \) as well as the variety \( \mathcal{A}_{S_{\lambda}}^{\text{Prin}}(s) \) from \( X_{s_{\lambda}} \) through \( D_s \).

8.1. RECONSTRUCT \( \mathcal{A}^{\text{Prin}}(s) \) FROM \( D_s \). Given fixed data \( \Gamma \) and an \( A \)-seed with principal coefficients \( s = (e, p) \), denote by \( \mathcal{A}^{\text{Prin}}(s) \) the corresponding generalized cluster algebra. Recall that we denote by \( x_{i,v} \) the cluster variables associated to the seed \( s_{\lambda} \).

Consider the generalized cluster scattering diagram \( D_s \), whose wall-crossing act on \( \mathbb{Q} \) by automorphisms. For two vertices \( v, v' \in T_s \), let \( \gamma \) be a path from the chamber \( C_{v \in S}^+ \) to \( C_{v' \in S}^+ \) and consider the path-ordered product
\[
p_{v,v'} = p^\gamma_{v,v'} := p_{\gamma,D_s} : \mathbb{Q} \rightarrow \mathbb{Q}.
\]
Since \( D_s \) is consistent and one can always choose some \( \gamma \) contained in the cluster complex, the path-ordered product \( p_{v,v'} \) can also be viewed as an automorphism of \( \text{Frac}(M \oplus \mathbb{P}) \).

**Proposition 8.1.** Let \( C_{v \in S}^+ \) be a cluster chamber and \( g_v \) the set of g-vectors. Then for any \( i \in I \),
\[
x_{i,v} = p_{v,v_0}(z^{p_{i,v}}) \in \text{Frac}(M \oplus \mathbb{P}).
\]
Proof. We prove this by induction on the distance from \(v\) to \(v_0\) in \(\mathcal{T}_s\). Suppose the statement is true for a vertex \(v \in \mathcal{T}_s\) and we have \(v \to v'\) in \(\mathcal{T}_s\). Then the chambers \(C^+_{v,0}\) and \(C^+_{v'}\) are separated by the wall \(\mathcal{D}_{v,v}\) with the wall-crossing \(f_{v,v}\) given in Theorem 7.10. Denote \(\varepsilon = \text{sgn}(g^1_{i,v}) \in \{+,-\}\). Then we have

\[
p_{v',v}(z^{g_i,v'}) = z^{g_i,v} \prod_{j=1}^r \left( 1 + p_{i,j,\mathcal{A}_s} \cdot \sum_{j=1}^n \varepsilon_j \beta_{j,v} + \gamma \right).
\]

By proposition 7.7, we have

\[
g_{i,v'} = -g_{i,v} + \sum_{j=1}^n \left[ -\varepsilon_j \beta_{j,v} \right] + g_{j,v'}.
\]

This leads to

\[
p_{v',v}(z^{g_i,v'}) = z^{-g_i,v} \prod_{j=1}^r \left( \sum_{j=1}^n \varepsilon_j \beta_{j,v} + g_{j,v'} + p_{i,j,\mathcal{A}_s} \cdot \sum_{j=1}^n \varepsilon_j \beta_{j,v} \right).
\]

Note that by sign coherence, \(p_{i,j,\mathcal{A}_s}\) has the same sign as \(\varepsilon\). So the above equation is exactly the exchange relation of cluster variables. Applying the path-ordered product \(p_{v,v_0}\) on both sides of the above equality finishes the induction. \(\square\)

By the generalized Laurent phenomenon Theorem 3.7, we know that \(x_{i,v}\) actually lives in \(\mathbb{k}[M \oplus \mathbb{P}]\).

Corollary 8.2. The set of cluster variables of \(\mathcal{A}_{\text{prin}}(s)\) is in bijection with the set of \(g\)-vectors.

Proof. We send a cluster variable \(x_{i,v}\) to the \(g\)-vector \(g_{i,v}\). To show that \(x_{i,v}\) is uniquely determined by \(g_{i,v}\), we observe that the formula \(p_{v,v_0}(z^{g_i,v})\) is independent of the choice of \(v\). Suppose there is another chamber \(C^+_{v,0}\) such that \(g_{i,v}\) is one of the generators. Choose a path \(\gamma\) from \(C^+_{v,0}\) to \(C^+_{v',0}\) close enough to the ray \(\mathbb{R}_+\cdot g_{i,v}\) so that it only crosses walls containing \(\mathbb{R}_+\cdot g_{i,v}\). The two path-ordered products \(p_{v,v_0}\) and \(p_{v',v_0}\) differ by \(p_\gamma\), which acts on \(z^{g_i,v}\) by identity. Thus \(p_{v,v_0}(z^{g_i,v}) = p_{v',v_0}(z^{g_i,v})\). \(\square\)

8.2. Reconstruct \(\mathcal{A}_{\text{prin}}\) from \(\mathcal{D}_s\). Recall that there is a surjective map from \(\mathcal{T}_s\) to \(\Delta^+\) (the set of cluster chambers) sending \(v\) to \(C^+_{v,0}\). For each vertex \(v \in \mathcal{T}_s\), we associate a torus \(T_{N,v}(R) = T_N(R)\). To a pair of vertices \(v, v'\), we associate the birational morphism

\[q_{v,v'} = q^*_{v,v'} : T_{N,v}(R) \to T_{N,v'}(R),\]

\[q^*_{v,v'} := p_{v',v}^* - p_{v,v'}^* \in \mathcal{A}_{\text{prin}}.
\]

Then there is an \(R\)-scheme obtained by glueing \(T_{N,v}(R), v \in \mathcal{T}_s\) via these birational morphisms

\[\mathcal{A}_{\text{prin}} := \bigcup_{v \in \mathcal{T}_s} T_{N,v}(R).
\]

One can actually relate \(\mathcal{A}_{\text{prin}}\) to the previously defined cluster variety

\[\mathcal{A}_{\text{prin}} := \bigcup_{v \in \mathcal{T}_s} T_{N,v}(R),
\]

which is obtained by glueing together the same set of tori via \(\Delta\)-cluster mutations.

Recall the piecewise linear map \(T_{v_0,v} : M_R \to M_R\) that sends the cluster chamber \(C^+_{v,0}\) to \(C^+_{v',0}\). When restricted to a domain of linearity, \(T_{v_0,v}\) becomes a linear automorphism on \(M\). Denote the restriction of \(T_{v_0,v}\) on \(C^+_{v,0}\) by \(T_{v_0,v}|_{C^+_{v,0}}\). In particular, \(T_{v_0,v}|_{C^+_{v,0}}\) is the identity map. These linear isomorphisms induce isomorphisms (or \(R\)-schemes) between tori

\[\psi_{v_0,v} : T_{N,v}(R) \to T_{N,v}(R), \quad \psi_{v_0,v}'(z^m) = z^{T_{v_0,v}|_{C^+_{v,0}}(m)}.
\]

Proposition 8.3. The isomorphisms \(\psi_{v_0,v}\) glue to be an isomorphism

\[\psi_{v_0} : \mathcal{A}_{\text{prin}} \to \mathcal{A}_{\text{prin}}.
\]

50
Proof. The morphisms $\mu_{v,v'}$ (resp. $q_{v,v'}$) are generated $\mu_{v_0,v}$ (resp. $q_{v_0,v}$) for all $v$ in $\Xi_s$. So the statement is equivalent to the commutativity of the following diagram (for any $v$).

\[
\begin{array}{ccc}
T_{N,s} & \xrightarrow{\psi_{v_0,v} = \text{id}} & T_{N,v_0 \in s} \\
\downarrow & & \downarrow \\
T_{N,s} & \xrightarrow{\psi_{v_0,v}} & T_{N,v \in s}
\end{array}
\]

To show $q_{v_0,v} = \psi_{v_0,v} \circ \mu_{v_0,v}$, we pull back the functions $z^{\partial_{i,v}}$ (for all $i \in I$) via these birational morphisms. On the left hand side, we get the cluster variables

\[x_{i:v} = q_{v_0,v}^* (z^{\partial_{i,v}})\]

by Proposition 8.1. On the right hand side, these $z^{\partial_{i,v}}$ get pulled back to $z^{\partial_{i,v}'}$ by $\psi_{v_0,v}$ as $T_{v_0,v_0 \in s}$ sends the chamber $C_{v_0 \in s}$ to the chamber $C_{v \in s}$. Then via $\mu_{v_0,v}$, we still get cluster variables

\[x_{i:v} = \mu_{v_0,v}^* (z^{\partial_{i,v}'})\]

As $\{g_{i:v} | i \in I\}$ form a basis of $M$, we conclude that $q_{v_0,v} = \psi_{v_0,v} \circ \mu_{v_0,v}$, which finishes the proof. 

We next see in a certain sense the variety $A_{k}^{\text{prin}}$ is independent of $s$. This is a subtle issue as for the cluster algebra $A^{\text{prin}}(s)$, the initial seed $\Sigma(s)$ is distinguished from others since it has principal coefficients.

To resolve this, we again treat $P$ as only a multiplicative abelian group. Consider $s' = \mu_k^+ (s)$ in the sense of Theorem 6.27. The tree $\Xi_{s'}$ is naturally embedded in $\Xi_s$, along with the association of seeds with coefficients. First of all, it is clear that the inclusion

\[\bigcup_{v \in \Xi_{s'}} T_{N,v \in s} \subset A_{\text{scat},s}^{\text{prin}}\]

is an equality. The glueing maps are given by path-ordered products of $D_s$.

Consider for $v \in \Xi_{s'}$, the isomorphism (of $R$-schemes)

\[\varphi_v : T_{N,v \in s'} \rightarrow T_{N,v \in s}\]

such that $\varphi_v^* : k[M \oplus P] \rightarrow k[M \oplus P]$ is given by the linear transformation

\[T_k |_{C_{v \in s}^+} : M \oplus P \rightarrow M \oplus P.\]

**Proposition 8.4.** The maps $\varphi_v$ for $v \in \Xi_{s'}$ glue together to have an isomorphism of $k[P]$-schemes

\[\varphi : A_{\text{scat},s'}^{\text{prin}} \rightarrow A_{\text{scat},s}^{\text{prin}}.\]

**Proof.** Let $v$ and $v'$ be two vertices in $\Xi_{s'}$. Since each $\partial_v$ is an isomorphism, the statement is equivalent to the commutativity of the following diagram (for any $v$ and $v'$).

\[
\begin{array}{ccc}
T_{N,v \in s'} & \xrightarrow{\varphi_v} & T_{N,v \in s} \\
\downarrow & & \downarrow \\
T_{N,v' \in s'} & \xrightarrow{\varphi_{v'}} & T_{N,v' \in s}
\end{array}
\]

In terms of algebras, this amounts to show

\[T_k |_{C_{v \in s}^+} \circ p_{v,v'}^* = p_{v',v'}^* \circ T_k |_{C_{v' \in s}^+} : k[M \oplus P] \rightarrow k[M \oplus P].\]
If the two chambers \( C_{v \in \mathbb{A}}^+ \) and \( C_{v \in \mathbb{A}}^+ \) are on the same side of the hyperplane \( e_k^+ \), the above equality is just (6.2). If they are separated by \( e_k^+ \), it is the same as (6.5) and has been check in (6.6).

 Combined with Proposition 8.3, we see that the construction \( \mathcal{A}_v^{\text{prin}} \) is independent of \( s \). In terms of the corresponding cluster algebra \( \mathcal{A}_v^{\text{prin}}(s) \), once it has principal coefficients on some seed \( s \), it can be made to do so at any seed mutation equivalent to \( s \).

### 8.3. Broken lines and theta functions.

This section is a recast of [GHKK18, Section 3] in the generalized situation. Recall the setting of scattering diagrams in Definition 6.5.

**Definition 8.5** (Broken line, cf. [GHKK18, Definition 3.1]). Let \( \mathcal{D} \) be a scattering diagram over \( \mathbb{K}[P] \) with a finite number of domains of linearity \( L_1, L_2, \ldots, L_k \) (open intervals in \( (-\infty, 0) \)), where each \( L = L_i \subset (-\infty, 0] \) is labeled by a monomial \( c_L z^{p_L} \in \mathbb{K}[P] \) with \( p_L \in P \). This data should satisfy:

1. \( \gamma(0) = Q \).
2. If \( L = L_1 \) is the first domain of linearity of \( \gamma \), i.e. \( L = (-\infty, t) \) for some \( t \leq 0 \), then \( c_L z^{p_L} = z^{p_0} \).
3. For \( t \in L \) any domain of linearity, \( m_L := r(p_L) = -\gamma'(t) \).
4. For two consecutive domains of linearity \( L = (a, t) \) (\( a \) can be \( -\infty \)) and \( L' = (t, b) \), the monomial \( c_L z^{p_L} \) is a term in the formal power series

\[
\varphi_{(a,t),\mathcal{D}}(c_L z^{p_L}) = c_L z^{p_L} \prod_{\gamma'(t) \in \mathcal{D}} f_{(a, b)}^{\langle n_0, m_L \rangle}.
\]

Here \( n_0 \in \mathbb{N} \) is primitive, serving as a normal vector of every \( \mathcal{D} \) appearing in the product such that \( \langle n_0, \gamma'(t) \rangle > 0 \). So the power \(-\langle n_0, m_L \rangle \) is always a positive integer.

**Definition 8.6** (Theta function, [GHKK18, Definition 3.3]). Let \( \mathcal{D} \) be a scattering diagram over \( \mathbb{K}[P] \). Let \( p_0 \in P \setminus \ker(r) \) and \( Q \in M_\mathbb{R} \setminus \text{Supp}(\mathcal{D}) \). For a broken line \( \gamma \) for \( p_0 \) with endpoint \( Q \), define

\[
\text{Mono}(\gamma) := c_Q z^{p_Q}
\]

where (by abuse of notation) \( Q \) stands for the last linear segment of \( \gamma \). We define the *theta function* for \( p_0 \) with endpoint \( Q \) as the formal sum

\[
\vartheta_{Q,p_0} := \sum_{\gamma} \text{Mono}(\gamma)
\]

where the sum is over the set of all broken lines for \( p_0 \) with endpoint \( Q \).

For \( p_0 = \ker(r) \), we define for any endpoint \( Q \)

\[
\vartheta_{Q,p_0} = z^{p_0}.
\]

We collect some important properties for theta functions from [GHKK18].

**Theorem 8.7.**

1. The theta function \( \vartheta_{Q,p_0} \) is in \( \mathbb{K}[P] \).
2. Suppose that \( \mathcal{D} \) is consistent. Then for \( Q, Q' \in M_\mathbb{R} \setminus \text{Supp}(\mathcal{D}) \) whose coordinates are linearly independent over \( \mathbb{Q} \), and \( p_0 \in P \),

\[
\vartheta_{Q',p_0} = \varphi_{\gamma,\mathcal{D}}(\vartheta_{Q,p_0})
\]

where \( \gamma \) is a path in \( \mathcal{D} \) from \( Q \) to \( Q' \) such that its path-ordered product is well-defined.
Proof. Part (1) essentially follows from the proof of [GHKK18, Proposition 3.4]. We are using a different monoid $P$ here, but the same proof still works with $J := m_P = P \setminus M$.

Part (2), as pointed out in the proof of [GHKK18, Theorem 3.5], is again a special case of [CPS22, Section 4]. Here the generic condition on the coordinates of $Q$ and $Q'$ is just to make sure that any broken line does not cross any joint of $D$. Modulo $m_P$, the independence of $\vartheta_{Q,m}$ on $Q$ within one chamber follows from [CPS22, Lemma 4.7]. The compatibility between $Q$ and $Q'$ in different chambers follows from [CPS22, Lemma 4.9]. See also a more general discussion on the globalness of theta functions in [GHS22, Section 3.3].

In the case of generalized cluster scattering diagrams $D_s$ (see Definition 6.17), the monoid $P$ is $M \oplus \bigoplus_{i \in I} \mathbb{N}v_i$ (contained in $M \oplus \mathbb{P}$) with the natural projection $r$ to the direct summand $M$. We have the following properties of theta functions.

**Proposition 8.8** (Mutation invariance of broken line, cf. [GHKK18, Proposition 3.6]). The piecewise linear transformation $T_k : M_\mathbb{R} \to M_\mathbb{R}$ (with a lift on $M \oplus \mathbb{P}$) defines a one-to-one correspondence $\gamma \mapsto T_k(\gamma)$ between broken lines for $p_0$ with endpoint $Q$ for $D_s$ and broken lines for $T_k(p_0)$ with endpoint $T_k(Q)$ for $D_{\mu_k(a)}$. This correspondence satisfies, depending on whether $Q \in \mathcal{H}_{k,+}$ or $\mathcal{H}_{k,-}$,

$$\text{Mono}(T_k(\gamma)) = T_k_{\pm}(\text{Mono}(\gamma))$$

where $T_k_{\pm}$ acts on a monomial as in Theorem 6.27. In particular, we have

$$\vartheta_{\mu_k(s)}^{T_k(Q), T_k(p_0)} = T_k_{\pm}(\vartheta_{\mu_k(p_0)}^{s})$$

Proof. We use $T_k(\gamma)$ to denote the piecewise linear map $T_k \circ \gamma : (-\infty, 0] \to M_\mathbb{R}$. Suppose $L$ is a domain of linearity of $\gamma$ labeled with monomial $c_L z^{p_L}$. If $\gamma(L)$ is contained in one of the half spaces $\mathcal{H}_{k, \pm}$, $L$ is also a domain of linearity for $T_k(\gamma)$. We apply the action of $T_k_{\pm}$ on the monomial $c_L z^{p_L}$ (where the sign is chosen depending on which half space $L$ is in). If $\gamma(L)$ crosses $c_L^\pm$, split $L$ into $L^+$ and $L^-$, and apply $T_k_{\pm}$ respectively to the monomial $c_L z^{p_L}$. One then needs to check the piecewise linear path $T_k \circ \gamma$ together with the new monomial data we just obtained is a broken line for $T_k(p_0)$ with endpoint $T_k(Q)$ in $D_{\mu_k(a)}$ as in [GHKK18, Proposition 3.6]. The inverse of the operation $\gamma \mapsto T_k \circ \gamma$ is also clear. The rest of the statement follows easily.

**Proposition 8.9** (cf. [GHKK18, Proposition 3.8]). Consider the scattering diagram $D_s$.

1. Let $Q \in \text{Int}(C_v^+)$ be an end point, and let $p \in P$ such that $r(p) \in C_v^+ \cap M$. Then $\vartheta_{Q,p} = z^p$.

2. Let $C_v^+ \in \Delta^+_s$ be a cluster chamber for some $v \in \mathcal{T}_s$, and $Q \in \text{Int}(C_v^+)$ and $m \in C_v^+ \cap M$. Then $\vartheta_{Q,p} = z^m$ if $r(p) = m$.

Proof. Part (1) is essentially [GHKK18, Proposition 3.8], although there the scattering diagram is actually different from $D_s$ in terms of wall-crossing functions. However, the bending behavior of a broken line on a wall is totally analogous, so the exact same argument still applies.

Part (2) is the generalized version of [GHKK18, Corollary 3.9]. By Proposition 8.8, the transformation $T_{v,v'} : M_\mathbb{R} \to M_\mathbb{R}$ defines a one-to-one correspondence between the broken lines for $p$ with $r(p) \in C_v^+ \cap M$ and $Q \in \text{Int}(C_v^+)$ in $D_s$, and the ones for $T_{v,v'}(p)$ with $r(T_{v,v'}(p)) \in C_v^+ \cap M$ and $T_{v,v'}(Q) \in \text{Int}(C_v^+)$. However the only broken lines of the later is labeled by the final monomial $z^p$ for $p' = T_{v,v'}(p)$ by part (1). The result follows.

### 8.4 Cluster monomials as theta functions.

**Definition 8.10.** Let $s$ be a generalized $A$-seed with principal coefficients. Then for $v \in \mathcal{T}_s$, a cluster monomial in this seed is a monomial on the torus $T_{N_v}(R) \subset A_s^{\text{prin}}$ of the form $z^m$ where $m$ is a non-negative $\mathbb{N}$-linear combination of $\{e_i \mid i \in I\}$. By the Laurent phenomenon, such a monomial extends to a regular function on the whole cluster variety $A_s^{\text{prin}}$. 

53
Remark 8.11. One may regard a cluster monomial as a function on the initial torus $T_{N,v_0}(R)$. While being a monomial on the cluster variables $x_{i,v}$, it is also a Laurent polynomial in the initial cluster variables $x_i$ by the Laurent phenomenon.

The following description of cluster monomials is a generalized version of [GHKK18, Theorem 4.9]. It proves the positivity (see Theorem 3.8) of generalized cluster monomials.

Theorem 8.12. Let $\mathcal{D}_s$ be the generalized cluster scattering diagram of a seed $s$. Let $Q \in \text{int}(C^+_s)$ a general end point and $m \in C^+_s \cap M$ for some $v \in \mathcal{T}_s$. Then the theta function $\vartheta_{Q,m}$ is an element in $z^m \cdot N[P]$ which expresses the cluster monomial associated to $m$ of the algebra $\mathcal{A}_{\text{prin}}(s)$ in the initial seed $s$.

Proof. We first note that $m$ is regarded as a point in $P$ through the inclusion of $M$ in $P$. Let $Q'$ be a base point in $\text{int}(C^+_s)$ and $\gamma$ be a path going from $Q'$ to $Q$. By part (2) of Theorem 8.7, we have

$$\vartheta_{m,Q} = p_{\gamma}(\vartheta_{m,Q'}).$$

As a theta function, $\vartheta_{m,Q}$ is a (formal) sum of monomials belonging to $z^m[N[P]]$. By the positivity Theorem 6.31 of $\mathcal{D}_s$, $\vartheta_{m,Q}$ has positive integer coefficients, thus an element in $z^m[N[P]]$. By part (2) of Proposition 8.9, $\vartheta_{m,Q'} = z^m$. We know that the cone $C^+_v$ has integral generators $\{g_{i,v} \mid i \in I\}$ in $M$. Thus $m$ is a non-negative linear combination of these $g$-vectors.

On the other hand, by Proposition 8.1, we have the following expression of a cluster variable

$$x_{i,v} = p_{\gamma}(z^{g_{i,v}}).$$

It follows immediately that $\vartheta_{m,Q}$ is a monomial of these $x_{i,v}$, thus expressing a cluster monomial. Finally by the generalized Laurent phenomenon Theorem 3.7, we have $\vartheta_{m,Q} \in z^m \cdot N[P]$. □

Since $\vartheta_{m,Q}$ does not depend on $Q$ as long as it is chosen generally in the positive chamber, we simply write it as $\vartheta_m$. Consider the set of functions

$$\{\vartheta_m \mid m \in \Delta^+_s(Z)\},$$

where $\Delta^+_s(Z) = \bigcup_{v \in \mathcal{T}_s} C^+_v \cap M$. These are all cluster monomials. In general, they do not form an $R$-basis of the cluster algebra $\mathcal{A}_{\text{prin}}(s)$ or the upper cluster algebra $\mathcal{A}_{\text{uppr}}(s)$. But one can follow [GHKK18, Section 7.1] to define the set $\Theta \subset M$ such that for any $m \in \Theta$, $\vartheta_m$ is only a sum of monomials from finitely many broken lines. Consider the free $R$-module

$$\text{mid}(\mathcal{A}_{\text{prin}}) := \bigoplus_{\Theta} R \cdot \vartheta_m.$$

It is shown in [GHKK18, Theorem 7.5] that in the ordinary case there are natural inclusions of $R$-modules

$$\mathcal{A}_{\text{prin}}(s) \subset \text{mid}(\mathcal{A}_{\text{prin}}) \subset \mathcal{A}_{\text{uppr}}(s)$$

such that for the first inclusion, cluster monomials are sent to the corresponding theta functions, and for the second inclusion, any theta function is sent to the corresponding universal Laurent polynomials on $\mathcal{A}_{\text{prin}}$ (see [GHKK18, Proposition 7.1]). We expect that this is also true in the generalized case.

8.5. More on positivity. In [CS14], the authors proposed a positivity conjecture which is stronger than Theorem 3.8. We formulate a version here.

A generalized cluster algebra in the sense of [CS14] (see Section 3.2) is called reciprocal if any of its exchange polynomials $\theta_i(u,v)$ is monic and palindromic, i.e. $\theta_i(u,v) = \theta_i(v,u)$ and has leading coefficient 1. In this way, the exchange polynomials do not change under mutations. Note that $\theta_i(u,v)$ can have coefficients in $\mathbb{Z}[P]$ (rather than just in $P$) in general.
Conjecture 8.13 (c.f. [CS14, Conjecture 5.1]). Any cluster variable of a reciprocal generalized cluster algebra whose exchange polynomials have coefficients in \( \mathbb{P} \) (or more generally in \( \mathbb{NP} \)) is expressed as a positive Laurent polynomial in the initial cluster, i.e. an element in \( \mathbb{NP}[x_1^\pm, \ldots, x_n^\pm] \) where the \( x_i \)'s are the initial cluster variables.

Chekhov and Shapiro pointed out that this conjecture is true for any generalized cluster algebra associated to a surface with arbitrary orbifold points [CS14, Section 5] (see also [BK20] for a proof using snake graphs). The rank two case of this conjecture has been resolved by Rupel in [Rup13].

We consider here a related situation where the reciprocal assumption is not required. Let \( \mathbb{P} \) be an abelian group of finite rank. Consider an algebraic closure \( k = \overline{\mathbb{QP}} \) of the field of rational functions \( \mathbb{QP} \). Let \( \mathcal{A}^{\text{prin}}(\Sigma) \) be a generalized cluster algebra with principal coefficients as of Definition 3.13. The coefficients group is the tropical semifield \( \text{Trop}(\mathbb{P}) \). Recall that the initial exchange polynomials have the form

\[
\theta_{i}(u,v) = \prod_{j=1}^{r_i} (p_{i,j} u + v).
\]

Let \( \lambda: \text{Trop}(\mathbb{P}) \to k^* \) be an evaluation (as in Section 3.5) such that each \( \lambda(\theta_{i}(u,v)) \) satisfies

(A) All its coefficients are in \( \mathbb{ZP} \) (in \( \mathbb{NP} \) if assuming positivity);
(B) \( \lambda(\prod_{j=1}^{r_i} p_{i,j}) \) is an element in \( \mathbb{P} \).

By the mutation formula of coefficients, the exchange polynomials after any steps of mutations still satisfy these two conditions. Therefore the cluster algebra with special coefficients \( \mathcal{A}^{\text{prin}}(\Sigma, \lambda) \) can be viewed as a generalized cluster algebra of [CS14] (with the coefficients group \( \mathbb{P} \)). Note that any reciprocal generalized cluster algebra can be obtained this way.

The scattering diagram \( \lambda(\mathcal{D}_s) \) (see Section 6.4) is responsible for \( \mathcal{A}^{\text{prin}}(\Sigma, \lambda) \). It is over \( k[M \oplus \prod_{i \in I} \mathbb{N}] \) with formal parameters \( t_i \). Note that by the generalized Laurent phenomenon, the cluster variables of \( \mathcal{A}^{\text{prin}}(\Sigma, \lambda) \) are all in \( \mathbb{ZP}[x_1^\pm, \ldots, x_n^\pm] \).

Theorem 8.14. Let \( \mathcal{A}^{\text{prin}}(\Sigma, \lambda) \) be a generalized cluster algebra as above assuming (A), (B), and that the initial exchange polynomials have coefficients in \( \mathbb{NP} \). Let \( s \) be an \( \mathcal{A} \)-seed such that \( \Sigma(s) = \Sigma \). If there exists a representative of \( \lambda(\mathcal{D}_s) \) such that every wall-crossing function is in \( \mathbb{NP}[M \oplus \prod_{i \in I} \mathbb{N}] \), then any cluster variable is expressed as a positive Laurent polynomial in the initial cluster, i.e. an element in \( \mathbb{NP}[x_1^\pm, \ldots, x_n^\pm] \).

Proof. As in Theorem 8.12, the positivity of cluster variables follows from the positivity of the scattering diagram \( \lambda(\mathcal{D}_s) \) since every broken line ends with a monomial with coefficients in \( \mathbb{NP} \subset k \). Expressing a cluster variable as a theta function for \( \lambda(\mathcal{D}_s) \) (and evaluated at \( t_i = 1 \) where the \( t_i \)'s are the standard generators of \( \prod_{i \in I} \mathbb{N} \)), the result follows.
