Abstract

The peptidoglycan (PG) layer is an intricate and dynamic component of the bacterial cell wall, which requires a constant balance between its synthesis and hydrolysis. FtsEX complex present on the inner membrane is shown to transduce signals to induce PG hydrolysis. FtsE has sequence similarity with the nucleotide-binding domain (NBDs) of ABC transporters. The NBDs in most of the ABC transporters couple ATP hydrolysis to transport molecules inside or outside the cell. Also, this reaction cycle is driven by the dimerization of NBDs. Though extensive studies have been carried out on the E. coli FtsEX complex, it remains elusive regarding how FtsEX complex helps in signal transduction or transportation of molecules. Also, very little is known about the biochemical properties and ATPase activities of FtsE. Because of its strong interaction with the membrane-bound protein FtsX, FtsE stays insoluble upon overexpression in E. coli, and thus, most studies on E. coli FtsE in the past have used refolded FtsE. Here in this paper, for the first time, we report the soluble expression, purification, and biochemical characterization of FtsE from E. coli. The purified soluble FtsE exhibits high thermal stability, exhibits ATPase activity and has more than one ATP-binding site. We have also demonstrated a direct interaction between FtsE and the cytoplasmic loop of FtsX. Together, our findings suggest that during bacterial division, the ATPase cycle of FtsE and its interaction with the FtsX cytoplasmic loop may help to regulate the peptidoglycan hydrolysis at the mid cell.

Keywords: ABC transporter, FtsEX, FtsE dimer, ATP-binding, and ATP hydrolysis.
1. Introduction

The bacterial cell division proceeds in two stages. In the first stage, chromosome segregation occurs, and in the second stage, the cell identifies the mid-cell position, where the division occurs. The constriction of cell envelope at the mid-cell assures the symmetric division of bacterial cells into two identical daughter cells. The reason for the occurrence of cytokinesis precisely at the mid-cell was unknown until the role of FtsZ in the assembly of the divisome was identified. FtsZ, a tubulin homolog, forms the core skeleton of the divisome by assembling into a ring-like structure at the mid-cell [1],[2]. The two other essential cell division proteins, ZipA, and FtsA help in stabilizing the Z-ring. FtsEX, an ABC transporter homolog [3], gets recruited to the Z-ring during the initial stages of the formation of the divisome complex [4],[5]. In the FtsEX complex, FtsE forms the nucleotide-binding domain (NBD), and FtsX forms the transmembrane domain (TMD), and both are essential for the bacterial division. The ABC transporters primarily function as exporters or importers through remarkable conformational changes upon nucleotide-binding and hydrolysis. Apart from their role as a transporter, these family proteins help in the activation of other proteins [6]. For example, FtsEX activates amidases through EnvC, which performs peptidoglycan hydrolysis during bacterial cytokinesis [7]. Similar to other NBDs, FtsE possesses all the conserved regions, including the signature motifs, and the conserved residues involved in ATP-hydrolysis. The ATPase cycle is a necessary event for regulating the open and closed conformations of TMDs in ABC-transporters. Since TMD of the FtsEX complex is shorter, it may not show any open or closed conformations. Thus, if *E. coli* FtsE (FtsE<sub>Ec</sub>) shows any ATPase cycle, it may regulate the peptidoglycan hydrolysis pathway at the mid cell by regulating FtsX.
During cell division, there is a continuous requirement of peptidoglycan (PG) hydrolysis at the mid-cell, and a regulated mechanism is essential to avoid breaches due to uncontrolled PG hydrolysis. Hence, the ATPase cycle by FtsE could be an essential event for the on/off mechanism of PG hydrolysis. Thus, it becomes critical to characterize the presence of the ATPase cycle and NBD-like functions of FtsE. In this work, we have used biochemical approaches and homology modeling to describe the functional and structural aspects of FtsE and its features similar to the NBDs of ABC-transporter. To date, no studies have reported FtsE Ec protein in the soluble fraction, and most of the works published are done with refolded protein. Here, we were able to purify FtsE from the soluble fraction and validate its function precisely.

2. Materials and methods
2.1. Materials:
HEPES, KCl, and sodium phosphate were from MP Biomedicals; LB broth and LB agar were from Himedia, and MANT-ATP was from Invitrogen. All other chemicals used were of molecular biology grade and purchased from Sigma-Aldrich.

2.2. Cloning and Mutagenesis:
The ftsE ORF was cloned at EcoRI and SalI restriction sites into a His-pBAD18 plasmid after amplifying from E.coli K12 genomic DNA. The clones were confirmed through colony PCR, restriction digestion, and finally, with ds DNA sequencing. Point mutations were generated by inverse PCR mutagenesis in ftsE. The plasmid with point mutations was treated with DpnI enzyme and incubated overnight at 37 °C. The DpnI-treated PCR product was transformed into E. coli DH5α cells, and the mutations were confirmed by ds DNA sequencing.
2.3. Expression and Protein Purification:

The plasmid with wildtype and mutant ftsE were transformed into E. coli C41 competent cells. Initially, the expression was checked with different percentages of arabinose, starting from 0.01 to 0.1% in LB broth, which was followed by checking the protein in the soluble fraction. A good amount of protein was obtained in the soluble fraction with 0.01% arabinose. So, a maxi-culture was performed using the same arabinose concentration. Maxi-culture was performed by inoculating the overnight culture into 1 liter of fresh LB broth and incubated at 30 °C in a shaker incubator till the OD_{600} reached 0.5. The protein expression was induced with 0.01% of arabinose at 16 °C in shaker incubator for 16 hrs. The cells were harvested by centrifugation at 7000 rpm for 10 min at 4 °C and resuspended with lysis buffer [25 mM sodium phosphate (pH 8.0), 300 mM KCl, 10 mM MgCl₂, 0.01% NP-40 and 10% glycerol]. The suspended cells were homogenized with glass homogenizer for 1 h in ice and then passed through a pressure cell homogenizer 4-5 times. The cell lysate was then centrifuged at 40,000×g for 2 hrs. The clarified supernatant was incubated with pre-equilibrated Ni-NTA resin beads at 4 °C for 1h. The resin beads were loaded into an empty gravity column, followed by washing of the beads with a wash buffer [25 mM HEPES (pH 7.5), 300 mM KCl and 25 mM imidazole]. Then the proteins were eluted with an elution buffer [25mM HEPES (pH 7.5), 150 mM KCl and 250 mM imidazole]. Fractions with relatively pure protein, as observed on an SDS-PAGE gel were pooled together and concentrated. Then the concentrated protein was subjected to size-exclusion chromatography (SEC) using a Superdex 75pg 16/600 column (GE Healthcare). The fractions from the second peak were collected and concentrated. Finally, the concentrated protein was once again passed through a Superdex 75pg 16/600 column, and the purified protein fractions were pooled together.
and concentrated. The concentrated protein was stored at -80 °C. Similarly, the mutant FtsE proteins were also purified (Fig. S2A).

2.4. Homology Modelling of FtsE:

The 3D structure of FtsE<sub>Ec</sub> was made using a homology modeling technique. We used the Phyre2 template-based modeling [8] to model the structure of FtsE<sub>Ec</sub>. The modeling was done in intensive mode using FtsE<sub>Ec</sub> protein sequence. Further, for atomic-level protein structure refinement, we used Fragment guided MD simulation [9] using an online interface of FG-MD (https://zhanglab.ccmb.med.umich.edu/FG-MD/). The model quality was further assessed by Ramachandran plot analysis using Phyre2 interface and RAMPAGE [10]. To further validate the correctness of the model, we used two other online homology modeling tools, including I-TASSER [11] and LOMETS [12,13]. All the structures were visualized and analyzed by PyMOL.

2.5. ATPase Assay:

The ATPase assay was performed using Malachite Green Method as described earlier [14]. A 100 µl reaction mixture was set up with different concentrations (1, 5, and 10 µM) of the FtsE protein and incubated with 10 mM MgCl<sub>2</sub> and 1 mM ATP at 37 °C for 30 min. The reaction mixture was quenched with 70% perchloric acid (1:10 volume). Then, 950 µl of Malachite green ammonium molybdate solution was added to 50 µl of the reaction mixture and incubated in the dark for 30 min at room temperature. Then the Pi released was calculated by measuring the absorbance at 650 nm and compared with the standard curve generated with sodium phosphate.

2.6. Fluorescence Binding Assay:
For determining the affinity of FtsE for ATP, 1 µM of MANT-ATP (a fluorescence analog of ATP) was incubated with varying concentrations of FtsE in a buffer containing 25 mM HEPES (pH 7.5), 50 mM KCl and 10 mM MgCl₂. The reaction mixture was excited at 350 nm (the excitation wavelength for MANT-ATP), and the emission spectra were collected in the 380-550 nm wavelength range. Then the change in fluorescence intensity was used to calculate the dissociation constant using a double reciprocal plot [15].

2.7. Job’s Plot Assay:

The stoichiometry of FtsE and ATP was assessed using the continuous variation method. Then the change in mant-ATP fluorescence was observed by increasing the mant-ATP concentration and decreasing the FtsE concentration while keeping the total concentration constant at 1 µM. The reaction was carried out with 25 mM HEPES, pH 7.5, 50 mM KCl, and 10 mM MgCl₂.

2.8. Analytical Size-Exclusion Chromatography:

Analytical gel-filtration chromatography was carried out with a Superdex 200 increase 10/300 GL column (GE Healthcare). The column was pre-equilibrated with a buffer containing 20 mM HEPES (pH 8.0) and 50 mM KCl, and 100 µl of the protein sample was injected and allowed to pass through the column at 4 °C with 0.5 ml/min flow rate in the same buffer. For molecular mass estimation of FtsE_Ec, the standard proteins from the gel-filtration high molecular weight calibration kit (GE Healthcare) were passed through the column in the same buffer at 4 °C, and molecular mass of the protein was calculated using Kav values.

2.9. CD Spectroscopy:

The near-UV CD (200-260 nm) spectrum was measured using a Circular Dichroism (CD) spectropolarimeter (JASCO-1500) to analyze the secondary structure content of FtsE_Ec. The
protein samples were diluted into 1xPBS to a concentration of 3 μM. The secondary structure content analysis was measured using CD multivariate SSE analysis option from SpectraManager software supplied with JASCO-1500 spectropolarimeter.

2.10. Molecular Docking of ATP:

The docking was performed using AutoDock/Vina [16] with default parameters to get more accurate results. The pdbqt files for protein and ligand preparation and grid box were performed using a graphical user interface of AutoDock tools. AutoDock/Vina was further employed to dock ATP on to the protein, FtsE<sub>Ec</sub>. The program AutoDock/Vina considers both protein and ligand as rigid objects during docking and uses iterated local search global optimizer [16]. A total number of 10 poses were given, and the pose with the lowest binding affinity was extracted and aligned with FtsE to identify the residues involved in the interaction. The lowest binding affinity observed from docking was -8.7Kcal/mol from the first pose and was analyzed for further interpretation.

2.11. Thermal Stability Assay:

The thermal stability assay was performed by using FtsE protein purified from NiNTA resin. The protein was heated in a dry bath at different temperatures for 10 min. The heated protein samples were centrifuged at 40,000 xg for 30 min. The supernatant and pellet were separated. To the pellet equal amount of buffer was added, and then both supernatant and pellet were loaded on SDS PAGE separately and visualized with coomassie stain.

2.12. Yeast two-hybrid (Y2H) assay:

Y2H was used to determine if FtsE interacts with itself following the previously established protocol [14]. The full-length FtsE was cloned in pGBT9 and pGAD424 separately. Both the
plasmids were subsequently transferred into competent yeast cells and grown in histidine deficient media.

2.13. **FtsE self-interaction and FtsE-FtsX interaction studies:**

For dimerization study, first of all the crude membrane fraction was obtained from *E. coli* (BL21) cell. The cells were lysed and centrifuged to remove the cytoplasmic proteins and then the pellet was used to isolate the membrane fraction using 0.1% Triton-X. A reaction mixture was set using purified His-FtsE and membrane fraction in the presence and absence of ATP and incubated in the ice for 1 hr. Then the mixture was passed through cobalt resin and the eluted fraction was loaded in the SDS-PAGE without boiling, then followed by western with anti-His monoclonal antibody. To check the interaction of FtsE with synthesized FtsX peptide (34 amino-acid from cytoplasmic fraction), purified FtsE (10 µM) was incubated with FtsX peptide (20 µM) with 10 mM MgCl2 and in the presence or absence of 2 mM ATP. The reaction mixtures were incubated in ice for 30 min followed by glutaraldehyde crosslinking for another 30 min at room temperature. The samples were checked using an SDS PAGE (18%).

3. **Results**

3.1. **Purification of *E. coli* FtsE in native condition:**

FtsEX complex is a homolog of ABC-transporter in *E. coli*. The sequence alignment shows the presence of the conserved consensus sequence (Fig. 2A) that confirms FtsE as the nucleotide-binding domain (NBD) in the FtsEX complex. Depending on the types of the transmembrane domain present, ABC transporters can function either as an exporter or an importer. However,
FtsE neither functions as an exporter nor an importer. To understand how FtsE functions as an NBD, we evaluated its properties in vitro. Previously, FtsE protein from *M. tuberculosis* was expressed in *E. coli* and purified using denaturation and renaturation [17]. We followed the similar protocol to purify *E. coli*-FtsE (FtsE<sub>Ec</sub>). We obtained a good amount of purified protein using this method (Fig. S1A), however, the refolded FtsE was eluted near to the void volume when passed through an analytical size-exclusion chromatography (Superdex 200 10/300 GL) (Fig. S1B). The CD analysis of the eluted fraction showed a poor secondary structure (data not shown) and very low ATPase activity suggesting non-functional protein (Fig. S3A). Therefore we modified our protocol to obtain functionally folded FtsE.

In the modified protocol, we used a His-pBAD18 vector system for the controlled expression of FtsE in *E.coli* C41 strains. The overexpression in this system was induced by 0.01% arabinose (w/v), and a large amount of FtsE was obtained in the soluble fraction. The purification was performed using Ni-NTA affinity chromatography, followed by two rounds of size-exclusion chromatography (Fig. 1A-C). To confirm the purified protein was FtsE, SDS PAGE and western blot was performed (Fig. S1C and S1D). In the analytical size-exclusion chromatography, FtsE (Fig. 4A) eluted as a monomer with an approximate molecular mass of 30.2 kDa (Fig. 1D and Fig. S2B). The CD spectroscopy verified the presence of both α-helices and β-sheets (Fig. S2C), as predicted by secondary structure prediction tools. Our initial characterization showed that the purified FtsE<sub>Ec</sub> is soluble; it has an intact secondary structure and remains as a monomer. This protein was further used for assessing its biochemical properties.

### 3.2. Homology model of FtsE<sub>Ec</sub> shows a typical NBD architecture:

To study the properties and functions of FtsE in *E. coli*, we evaluated the FtsE structure computationally. The multiple sequence alignment of FtsE<sub>Ec</sub> showed ~42% sequence identity
with methionine importer, MetNI, from *E. coli* (strain K12). The other structural homologs of FtsE<sub>Ec</sub> with more than 35% sequence identity include an ABC-transporter MacB from *Acinetobacter baumannii* (39.3%), a non-canonical ABC-transporter from *S. pneumoniae* (R6 strain) (36.4%), an ABC-transporter from *Aquifex aeolicus* (36.3%) and ArtP from *Geobacillus stearothermophilus*. The sequence alignment reveals that the consensus sequences of ABC-transporter family proteins such as Walker A, Walker B motif, Q-loop, D-loop, H-loop, and the signature motif (LSGGQ) are conserved in FtsE<sub>Ec</sub> (*Fig. 2A*) suggesting FtsE<sub>Ec</sub> as a member of the ABC-transporter family. The structure of FtsE<sub>Ec</sub> was predicted by comparative modeling using Phyre2 prediction server, which showed more than 90% confidence for the secondary structural elements [8]. Further validation of the predicted structure was performed using separate online modeling tools based on different algorithms such as I-TASSER [11] and LOMETS [12],[13]. All the predicted structures showed secondary structures similar to that obtained by Phyre2, and therefore it was used for further analysis.

The structural analysis showed that FtsE<sub>Ec</sub> contains 11 β-sheets and 8 α-helices. The β-strands are present as anti-parallel β-sheets arranged in two halves forming a pocket-like structure with α1 helix inserted inside it. The other α-helices lie on the other half of the structure. The Walker-A motif lies in α1 helix and loop connecting β5 and α1. Whereas, the Walker-B motif lies in the β8 strand (*Fig. 2A-B*). We also observed more number of hydrophobic residues distributed over the surface of FtsE (*Fig. 2C*). A higher distribution of hydrophobic residues over the surface may account for the overall higher stability of FtsE<sub>Ec</sub> protein. Thus, the thermal stability of FtsE<sub>Ec</sub> was checked by heating the protein sample at different temperatures. The data shows that FtsE possesses higher thermal stability (*Fig. 2D*), which was also verified using CD-spectroscopy.
Furthermore, the surface electrostatics distribution of the FtsE<sub>Ec</sub> model showed an even charge distribution on both the faces (Fig. S2D).

### 3.3. FtsE<sub>Ec</sub> interacts with ATP and shows ATPase activity similar to NBDs:

The ABC-transporters shows a conserved architecture, where two TMDs associate with each other to form translocon channel and substrate binding sites. The crystal structure of NBDs in the nucleotide-binding state or the whole transporter shows a symmetrical sandwich dimer, where two nucleotides are bound at the monomer-monomer interface of NBDs [18]. Two alternative models have been proposed for NBD’s function; processive clamp or switch model and constant contact model [19]. In the processive clamp model, NBDs undergo a cycle of ATP binding followed by dimer formation, which further follows ATP hydrolysis and NBD dimer dissociation. Alternatively, in constant contact model, the NBDs always remain in the asymmetric state, and only one nucleotide stay tightly bound at a time [20].

To identify the ATP-binding pattern of FtsE<sub>Ec</sub> and its model of function, we performed fluorescence binding assay. FtsE<sub>Ec</sub> was titrated against MANT-ATP, and the change in fluorescence intensity was used to calculate the dissociation constant. Our results indicated the presence of two binding sites in wildtype FtsE, with a high-affinity site (K<sub>d</sub> = 21.5 ± 2.2 nM) and a moderate affinity site (K<sub>d</sub> = 1.14 ± 0.24 µM) (Fig. 3B). The results clearly showed that, like NBDs, the binding of ATP to FtsE<sub>Ec</sub> is sequential. To verify the same, we determined the stoichiometry of the FtsE-MANT-ATP complex using the continuous variation method. Our result showed that more than one number of ATP (~1.5) interact with FtsE (Fig. 3E).

We also assessed the ATPase activity of wildtype, ATP-binding deficient mutants (K41A, C49A) and refolded FtsE in vitro. Wild type FtsE<sub>Ec</sub> showed an increase in ATPase activity in a
concentration-dependent manner (**Fig. 3A**). The rate of ATPase activity was found to be 0.14 ± 0.01 nmoles of Pi/nmoles of protein/min for wildtype FtsE. Whereas, the refolded FtsE<sub>Ec</sub> showed much lower ATPase activity compared to the native FtsE<sub>Ec</sub> (**Fig. S3A**). When the lysine residue that forms the Walker-A loop (K41 in *E.coli* FtsE) and binds to ATP was mutated to alanine (FtsE<sup>K41A</sup>), the ATPase activity was reduced by 50-90% (**Fig. 3A**). The reduced ATPase activity suggests that mutation at a single site did not abolish the ATPase activity of FtsE<sub>Ec</sub> completely. We also checked the ATP binding affinity for FtsE<sup>K41A</sup>, and it was found to be much lower than wildtype FtsE (**Fig. 3C-D**). Similarly, mutation of cysteine (C49) to alanine (FtsE<sup>C49A</sup>), a residue reported to be involved in FtsE dimerization [21], showed a decreased ATPase activity (by 30%) compared to the wildtype FtsE<sub>Ec</sub> (**Fig. 3A**). Since cysteine residue is present adjacent to the Walker-A motif, a mutation of cysteine residue may lead to a decrease in the ATP binding and, eventually, ATPase activity.

### 3.4 FtsE self-interaction and its interaction with FtsX:

From ATP-binding and the ATPase assays with wildtype and mutant FtsE, we observed that more than one ATP-binding sites are present in FtsE<sub>Ec</sub>. To further probe whether ATP binds to the same residues as in other NBDs, we docked ATP over the FtsE<sub>Ec</sub> monomer model using Autodock Vina [16]. The docking prediction shows that K41 of the Walker-A motif of FtsE<sub>Ec</sub> monomer is involved in binding with ATP (**Fig. S3C-D**) and the corresponding lysine-residue in the Walker-A motif is a conserved residue for ATP-binding in NBDs. Thus, if FtsE<sub>Ec</sub> forms a dimer, two ATP molecules could be present at the dimer interface, where each of the monomers would contribute one nucleotide. To check the possibility of FtsE<sub>Ec</sub> forming a dimer experimentally, we first performed analytical size-exclusion chromatography (SEC) of FtsE<sub>Ec</sub> with ATP and FtsE<sub>Ec</sub> without ATP. SEC result did not show any difference in the elution profile...
or peak position in both the cases (Fig. 4A-B). We also performed glutaraldehyde cross-linking and checked the samples on an SDS PAGE. Here again, FtsEec, both in the absence and presence of ATP, ran as a monomer and did not show any dimer formation (Fig. 4C). We further performed a yeast two-hybrid assay, which also showed no direct interaction between FtsE monomers (Fig. 4E). Thus our results suggested that FtsEec could not dimerize alone or in the presence of ATP. Next, we aimed to check whether any interacting partners are required for the dimerization of FtsE. FtsZ is known to interact with FtsEec directly, and thus we performed a glutaraldehyde cross-linking experiment on FtsEec in the presence of FtsZ and ATP. However, we did not see any FtsE dimers (Fig. 4D). From the above results, we summarize that FtsEec does not form a functional homodimer alone or in the presence of either ATP, FtsZ, or both.

Nevertheless, we could not ignore the possibility of the requirement of its interacting partner, FtsX, for forming a stable dimer. To check this possibility, we incubated His-purified FtsE in the presence of ATP and with the cytoplasmic fraction, or the membrane fraction of E. coli lysate. The sample was subjected to semi-denaturing SDS-PAGE and western blotting using an anti-His antibody. Interestingly, FtsE showed two bands in SDS-PAGE, one at ~ 26 Kda and second at ~ 55 kDa, whereas, in the presence of the cytoplasmic fraction, FtsE run as a monomer (Fig. S3B). Although the western blot confirmed the presence of FtsE at both the positions, it did not conclude if the upper band is due to FtsE homodimer or due to the formation of a heterocomplex with any of its membrane partner such as FtsX (Fig. 5A). To further confirm the involvement of FtsX, we synthesized a 34 amino acid peptide from the cytoplasmic loop of FtsX (TMD2 to TMD3), and the FtsE dimerization experiment was performed in its presence. Then after glutaraldehyde cross-linking, the samples were run on an SDS-PAGE.
Interestingly, we did not observe any FtsE dimer; instead, we found that FtsE and FtsX peptide were interacting with each other and showing a shift in FtsE band to ~ 30 KDa size (Fig. 5B). Our results indicated that FtsE<sub>Ec</sub> might not homodimerize in in-vitro condition, whereas, it may form a heterocomplex with FtsX even in the absence of ATP. Our results also suggested that FtsE-FtsX interaction is not dependent on ATP. However, the cases may be different during in-vivo, and further investigation is required to understand if and how FtsE is forming the dimers.

4. Discussion

FtsEX complex is an ABC transporter homolog, where FtsE is the NBD, and FtsX is the transmembrane domain. Unlike other ABC transporters, FtsEX is not involved in membrane transportation. The predicted structure of FtsX contains a large extra periplasmic loop suggesting its role in the signaling pathway [22]. During bacterial cell division, this extra periplasmic loop of FtsX interacts with EnvC that activates the amidases A & B and initiates PG hydrolysis at the mid-cell [7]. On the other hand, the ATPase activity of FtsE and its interaction with the cytoplasmic loop of FtsX regulates the PG hydrolysis. FtsEX complex does not transport anything. However, a significant question is whether FtsE functions like an NBD, i.e., whether it forms an active dimer and possesses ATPase activity.

To answer this question, we elucidated the NBD-like functions of FtsE<sub>Ec</sub> in vitro. We initially purified FtsE<sub>Ec</sub> from inclusion bodies by denaturation and refolding. However, analytical-SEC and CD spectroscopy showed that the refolded FtsE<sub>Ec</sub> forms larger aggregates with minimal secondary structures. Thus, FtsE was further purified from the soluble fraction; this protein
showed proper secondary structures and did not show any aggregation (Fig. 4A, S2C). Presence of the hydrophobic residues on the surface can stabilize globular proteins and can increase the thermal stability of a protein [23]. In FtsE, more number of hydrophobic residues appear to be clustered along with polar residues on surface (Fig. S3D) that may increase its thermal stability. This was also evident from our result that showed higher thermal stability for purified FtsE (Fig. 2D). The ATPase activity of the purified natively folded FtsE was much higher than that of the refolded FtsE (Fig. S3A). The homology model of FtsE_Ec showed an architecture similar to NBDs and suggested that it may form an active dimer (Fig. 2B). However, the glutaraldehyde cross-linking, analytical-SEC experiments, and the yeast two-hybrid assay showed that FtsE does not form any dimer in vitro either in the absence or presence of ATP. Our findings are similar to the results obtained from previous studies where FtsE from S. pneumoniae also did not form an active dimer with glutaraldehyde cross-linking [24]. Thus apart from ATP, FtsE might need its cognate partners FtsX or some other substrate for its dimerization. To verify this, we performed the dimerization of FtsE in the presence of E. coli membrane fraction and ATP.

Interestingly, in the presence of the E. coli membrane fraction, FtsE showed an upper band at the molecular size similar to FtsE homodimer or FtsE-FtsX hetero-complex (Fig. 5A). To verify this, we designed a small peptide from the cytoplasmic loop of FtsX and performed the FtsE dimerization experiment. Our result showed that in the in vitro experiment condition, FtsE did not form any dimer, but it interacted with the FtsX-peptide (Fig. 5B). This observation suggested that the shift in FtsE band to dimer position in the presence of the E. coli membrane fraction (Fig. 5A) might be due to the formation of a hetero-complex of FtsE and FtsX. Our result confirmed that the cytoplasmic loop of FtsX is responsible for FtsE-FtsX interaction, which was initially a prediction.
We also observed that the FtsE-FtsX peptide interaction is not ATP dependent. Although we were unable to show FtsE dimerization *in vitro*, it could be possible that our experiment did not mimic the exact required condition for FtsE dimerization. The experiment might require other components like an intact membrane or full-length FtsX. The dimerization of ABC transporters requires two ATP binding sites in each monomer, where the ATPs are shared among the FtsE<sub>Ec</sub> monomers to facilitate the dimerization. Using fluorescence binding assay and the Job’s plot assay, we observed that FtsE<sub>Ec</sub> contains more than one ATP binding sites (Fig. 3B-E). Lys41 is known to interact with ATP. Our molecular docking results also showed that Lys41 interacts with the three phosphates, similar to shown for other NBDs [25]. However, this FtsE mutant (K41A) still showed some ATPase activity, that further supports the presence of two ATP-binding sites in FtsE. In wildtype FtsE, we observed the presence of two ATP binding sites, one with higher affinity (25 nM) and another with a moderate affinity (1 µM). As lysine41 residue is the primary residue, we observed from our docking results, and from literature, we assumed that the higher affinity site is for lysine residue from the walker-A motif and moderate site is for serine residue from the signature motif. Considering this hypothesis, we initially expected a moderate affinity (1µM) for the FtsE<sup>K41A</sup> mutant. Unfortunately, we couldn’t calculate the exact affinity of FtsE<sup>K41A</sup> for ATP, as we could not achieve higher protein concentration due to its extensive sticky behavior. However, from the fluorescence binding experiment, we observed it to have weaker affinity compared to wildtype FtsE. The probable reason for this might be, binding of ATP at lysine residue enhances the second ATP binding affinity for serine residue. Thus the mutation of lysine41 to alanine could further reduce the affinity of FtsE for ATP at the second binding site serine139. This could be the probable reason for not seeing the moderate binding of ATP in the FtsEK41A mutant.
Our study indicated that, like other NBDs, FtsE<sub>Ec</sub> also contains two ATP-binding sites and follows the ATPase cycle. The ATPase cycle and its interaction with FtsE probably are regulating the PG hydrolysis at the mid cell by controlling the on/off switch of the amidases activation.

**Data Availability Statement:** All supporting data are included within the main article and its supplementary files.

**Declaration of competing interest:** The authors declare no conflict of interest.

**Acknowledgments:** The study was supported by funding to TKB by the Department of Biotechnology, India (Grant No. BT/PR21546/BRB/10/1560/2016) and core funding from the Institute of Life Sciences.

**Author Contributions:** SM and TKB designed the experiments. SM executed all the biochemical experiments. AK performed homology modeling, molecular docking, and CD spectroscopy experiments. HD and CA helped in gene cloning and protein purification work. SM, AK, DV, and TKB analyzed the data and wrote the manuscript.

Figure Legends

Figure 1. Purification of soluble FtsE: FtsE was purified using NiNTA affinity chromatography, followed by size-exclusion chromatography: Panel A, shows the SDS-PAGE image for His-FtsE purified using Ni-NTA resin. Panel B shows the chromatogram and the SDS-PAGE image for purified His-FtsE using the Superdex 75pg column. Panel C shows the chromatogram and the SDS-PAGE image for the second round of purification of His-FtsE using the Superdex 75pg column. Panel D shows the purified soluble FtsE.

Figure 2. Sequence alignment of FtsEEC with ABC-transporter family proteins and structure analysis using the predicted model of FtsE: Panel A, shows the sequence alignment of E. coli with the FtsE sequence from Acinetobacter baumannii MacB (Ab_MacB), Aggregatibacter actinomycetemcomitans MacB (Aa_MacB), Geobacillus stearothermophilus ArtP (Gs_ArtP), and E. coli methionine importer (Ec_MetNI). Panel B, the structure of E. coli FtsE, showing all the conserved motifs within the structure (Red: Walker-A, Blue: Walker-B, Pink: Q-loop, Green: D-loop, Purple: H-loop, and Cyan: the signature motif). Panel C, the distribution of hydrophobic residues across the FtsE surface (regions colored in White, represents the hydrophobic residues). Panel D, SDS-PAGE image showing the thermal stability of the recombinant FtsE: P-pellet, S-supernatant.

Figure 3. ATPase activity and ATP binding: The ATPase activity and ATP-binding studies were performed as described in the method section. Panel A shows the ATPase activity of wildtype FtsE and the two mutant versions of FtsE (EC49A and EK41A). Panel B, ATP-binding affinity of FtsE, was performed using fluorescence binding assay. Panel C, Graph showing the fluorescence intensity of MANT-ATP in the presence of wildtype FtsE and ATP binding mutant of FtsE (K41A). Panel D, Dendrogram is showing the relative fluorescence intensity of wildtype and mutant FtsE. Panel E, Job’s plot showing the binding ratio of FtsE and ATP (Mant-ATP used for fluorescence excitation).

Figure 4. FtsE self-interaction: FtsE self-interaction was performed using SEC and glutaraldehyde cross-linking. Analytical size-exclusion chromatogram for FtsE in the absence (Panel A) and the presence of ATP (Panel B) are shown. Panel C, the SDS PAGE image, is showing glutaraldehyde cross-linking of FtsE in the presence and absence of γ-ATP. Panel D, the
SDS-PAGE showing glutaraldehyde cross-linking of FtsE in the presence of FtsZ and γ-ATP.

**Panel E**, Yeast two-hybrid experiment showing the FtsE self-interaction.

**Figure 5. Interaction of FtsE with a cytoplasmic peptide of FtsX: Panel A**, western blot with anti-His antibody, indicating FtsE-FtsX complex formation in the presence of *E. coli* membrane fraction. **Panel B**, 18% SDS PAGE showing glutaraldehyde cross-linking of FtsE and cytoplasmic loop of FtsX (FtsX-peptide).

Supplementary Materials:
**Fig. S1. Purified native and refolded FtsE.** (A) Refolded and purified FtsE protein, the SDS PAGE image for refolded FtsE in 0.5M arginine, and purified from inclusion bodies. (B) Analytical size-exclusion chromatography profile for the refolded FtsE, eluting near to the void volume by using Superdex 200 10/300 GL column. (C) SDS PAGE image for soluble final purified FtsE. (D) Western blot with the anti-His antibody of FtsE during steps of checking solubility and purification. In: Induced, TS: Total supernatant, FL: Flowthrough, W: Wash fraction, F1: Elution fraction 1, F2: Elution fraction 2, F3: Elution fraction 3.
Fig. S2. Molecular weight calculation, CD spectra and surface charge distribution of FtsE.  
(A) The SDS-PAGE image of final purified mutant FtsE proteins from the soluble fraction. (B) Molecular weight calculation of the final purified soluble FtsE by following the equation described in materials and methods. (C) CD spectrum of FtsE obtained in soluble form and purified revealing proper secondary structure and hence folding with approximately 36.9% helix, 28.9% beta-sheet, and 5.3% turn. (D) Surface charge distribution of modeled FtsE.
**Fig. S3.** ATPase activity of refolded FtsE and in silico interaction of ATP with FtsE. (A). Dendrogram showing the ATPase activity of refolded FtsE. (B) Western blot with the anti-His antibody showing the absence of dimerization of FtsE in the presence and absence of the bacterial cytoplasmic fraction. (C) Docking of FtsE modeled structure with ATP, showing its interaction with K41 residue. (D) Enlarged view of FtsE with the docked ATP shows the interaction of lysine residue from the Walker-A motif and all the phosphate groups of ATP.
Figure S4. Uncropped western blots shown in the manuscript. Panel A shows the original western blot, from which Fig. 5A was made. Panel B and panel C show the western blot from which S1D and S3B were made. All lanes shown in the western blot were used.
