Abstract: We examine how generalised geometries can be associated with a labelled Dynkin diagram built around a gravity line. We present a series of new generalised geometries based on the groups $\text{Spin}(d,d) \times \mathbb{R}^+$ for which the generalised tangent space transforms in a spinor representation of the group. In low dimensions these all appear in subsectors of maximal supergravity theories. The case $d = 8$ provides a geometry for eight-dimensional backgrounds of M theory with only seven-form flux, which have not been included in any previous geometric construction. This geometry is also one of a series of “half-exceptional” geometries, which “geometrise” a six-form gauge field. In the appendix, we consider examples of other algebras appearing in gravitational theories and give a method to derive the Dynkin labels for the “section condition” in general. We argue that generalised geometry can describe restrictions and subsectors of many gravitational theories.

1 Introduction

Generalised geometry \cite{1,2} is the study of structures, analogous to those of ordinary differential geometry, defined on an extended tangent space \( E \simeq T \oplus \ldots \), which is generically twisted by some gerbe (or “gerbe-like”) structure. In \cite{3–5}, it was shown that there is a very natural formulation of certain supergravity theories in the language of generalised geometry. This article serves as a discussion of how one might directly apply this construction to more general algebras and theories. Significant work in this direction \cite{6} has already appeared in the mathematics literature\(^1\), and here we will present some new examples.

Thus far, generalised geometries based around the groups \( O(d,d) \) and \( E_d(d) \) (for \( d \leq 7 \)) and their relevance to physics have been well-studied \cite{7–17} (see also the literature on doubled constructions \cite{18–22} and other extended geometries \cite{23–28}). There has also been some work on generalised geometry for the groups \( O(d,d+n) \) \cite{6,29,30} (see also \cite{31}) and recently reduction of Courant algebroids \cite{32} on principal bundles has been used to describe the non-abelian generalisation \cite{33}.

However, as shown in \cite{6}, one can associate similar Leibnitz algebroids to more general classes of Lie algebras. In fact the only necessary condition is the existence of a \( GL(d,\mathbb{R}) \) subalgebra, under which the decomposition of the adjoint representation consists only of this subalgebra and exterior powers of the standard representation and its dual. Examples of such algebras were presented in \cite{6}, based on the \( B, D \) and \( E \) series of Lie algebras. In this paper we will provide new classes of examples, and explain how they appear in supergravity.

In particular we will present a new series of generalised geometries based on the groups \( \text{Spin}(d,d) \times \mathbb{R}^+ \), with the generalised tangent space transforming as a spinor representation. This will include a \((d-2)\)-form potential in the geometry. We also mention a similar series based on the group \( \text{SL}(d+1,\mathbb{R}) \times \mathbb{R}^+ \), which will include a \((d-1)\)-form potential. In this case the generalised tangent space will be the antisymmetric bi-vector representation.

The algebras we study here will all correspond to real forms of a Dynkin diagram with a so-called gravity line of nodes associated to a \( GL(d,\mathbb{R}) \) subalgebra, as in \cite{34}. We consider only finite dimensional algebras and always include an overall \( \mathbb{R}^+ \) factor as in \cite{3–5}. We label the standard representation of the \( GL(d,\mathbb{R}) \) subalgebra as \( T,^2\) using

\(^1\)We thank Marco Gualiteri for pointing out the direct relevance of this reference to the research presented here.

\(^2\)We slightly abuse notation in not distinguishing carefully between this representation and the tangent bundle of a \( d \)-dimensional manifold in a way which will hopefully not cause confusion.
the convention that $T$ corresponds to the Dynkin node at the left end of the gravity line, while the node at the right end corresponds to $T^*$.

\[
\begin{array}{ccccc}
\text{T} & - & - & - & \text{T}^* \\
\end{array}
\]

This distinction will prove to be important in constructing our new examples of generalised geometries. In a sense, we will simply reverse the orientation of the gravity line of some previously known cases.

To this gravity line can be attached other nodes. For example, one could attach a node with a single line to the $p^{th}$ node from the right

\[
\begin{array}{ccccc}
\text{\Lambda}^p & \text{T}^* & \cdots & \text{\Lambda}^2 & \text{T}^* \\
\end{array}
\]

Schematically, this will add a generator of the form $\Lambda^p T \oplus \Lambda^p T^*$ to the $GL(d, \mathbb{R})$ decomposition of the adjoint, as well as generators which arise from commutators involving these. Such a term in the adjoint representation is related to a $p$-form potential in the corresponding gravitational theory. This pattern holds for zero-form and top-form potentials, for which there is no associated Dynkin node so one adds an $SL(2, \mathbb{R})$ factor, and also for more exotic fields such as the dual graviton of [35–37]. We devote appendix B to exploring these patterns by means of several examples, with references to the literature as all of these examples have appeared before.

We observe that the Dynkin label corresponding to the generalised tangent space always has the form $[1, 0, \ldots, 0; *]$ where the labels before the semi-colon are those of the gravity line. The embedding of $GL(d, \mathbb{R})$ in the enlarged algebra is defined so that the decomposition of this representation has the form $T \oplus (\ldots)$. We will draw the Dynkin diagrams with the nodes corresponding to the generalised tangent space labelled with an $E$. In fact, the representation theoretical structure of the so-called “section condition” [4, 21, 25, 42] (or rather its complement in $S^2E$) can also be read off from looking at Dynkin labels. This is described in appendix A.2. The $T$ part of the generalised tangent space is stabilised by a parabolic subgroup. Moreover, any subspace which is null in the section condition is also stabilised by such a subgroup. The corresponding parabolic subalgebra was described in [6]. The parabolic subalgebras are in one-to-one correspondence with the set of subsets of nodes of the Dynkin diagram, the one of relevance here corresponding to the gravity line. Note that if the gravity line corresponds to a non-maximal $GL(d, \mathbb{R})$ subalgebra, then the null subspace is also not maximal. This occurs, for example, in the type II decompositions of [4].
Most such diagrams that one can draw do not give rise to generalised geometries. This is because of the appearance of tensor fields with mixed Young tableaux symmetry, as in [35], such as the dual graviton. As the non-linear construction of physical theories based on these types of fields is highly problematic, it is not surprising to find that the simple generalised geometry construction fails in these cases. The central problem here is that the Dorfman derivative fails to be covariant under diffeomorphisms\(^3\). This is due to the absence of a diffeomorphism covariant notion of gauge transformations for these mixed symmetry fields. We will deliberately endeavour to avoid these fields throughout this paper, giving only a brief algebraic discussion in appendix B. References on this include [38, 40, 41].

However, if the decomposition of the adjoint representation contains only \(T \otimes T^*\) (the \(GL(d, \mathbb{R})\) subalgebra) and pairs like \(\Lambda^p T \oplus \Lambda^p T^*\), then the algebra will give rise to a generalised geometry. This fact was observed in [6] and corresponds to the fact that the projection which defines the Dorfman derivative (see [4]) is diffeomorphism covariant if it only involves the exterior derivative and Lie derivative.

A point that we will pick up on in this paper is the idea of considering geometries built from sub-algebras of the full continuous “U-duality” [43] algebra. In particular we choose subalgebras of the type described above, and these will geometrise only a subsector of the field content. Indeed the original \(O(d, d)\) generalised geometry [1–3] includes only the NS-NS sector of the field content of type II supergravity. There are cases where the full algebra does not give rise to a geometry, but the subalgebra does. The \(Spin(8, 8) \times \mathbb{R}^+\) geometry in section 2 provides an example of this, as it is a subalgebra of \(E_{8(8)} \times \mathbb{R}^+\), for which there is no corresponding geometry. Another example is sketched in appendix B.4.5.

We conclude this introductory section with a brief discussion of how all of this fits into the literature on hidden symmetries in supergravity. Firstly, we note that the connections between algebras of the types described above and supergravity has a long history. The appearance of such symmetries goes back to [44] and was further developed in [45]. The idea that integral exceptional groups could be exact symmetries of quantised string theory was first proposed in [43]. Later, much wider proposals emerged of how infinite dimensional algebras could underly eleven-dimensional supergravity and M theory [36, 46, 47]. A more systematic investigation of their appearance and the identification of the various terms appearing at low levels in the decompositions was performed in [34, 40, 49] (see also an earlier work [48] which considers the finite dimensional cases). (We emphasise that much of the above schematic discussion of the

---

\(^3\)There are also algebraic issues (see e.g. [27]), which may be cured by including the external space in the context of dimensionally restricted theories [38]. This approach is inspired by the tensor hierarchy [39].
structure of the algebras is contained in these references as well as far more rigorous
details.) This was continued in [50], where interpretations were found for some of the
higher level terms, arguing that infinitely many of them are higher dual versions of
the original supergravity fields. Similar algebraic constructions for type II [51], half-
maximal [52] and also eight supercharge theories [53, 54] have been worked out. One
purpose of the present paper is to explore generalised geometries based around (the
finite dimensional cases of) these algebraic constructions. In particular, we wish to
describe the dynamics geometrically using the Dorfman derivative, where the above
references consider non-linear realisations.

This paper is organised as follows. In section 2 we introduce $Spin(d, d) \times \mathbb{R}^+$
generalised geometry and its appearance in supergravity. In section 3 we discuss a
series of “half-exceptional” geometries, which correspond to a subsector of the full
$E_{d(d)} \times \mathbb{R}^+$ geometries including only the six-form gauge field. There it is seen how the
$Spin(8, 8) \times \mathbb{R}^+$ geometry provides the $d = 8$ case of this series, and supersymmetry
variations are derived from it. In these two main sections, the general prescription for
the geometry is exactly that of [4, 5]. For this reason, the discussion is not as explicit
as that in [4, 5], but the details are straightforward to derive. Section 4 contains some
discussion of the results.

We begin appendix A with details of conventions. We also show how to find
the “section condition” for an arbitrary Dynkin diagram and also give some technical
details related to the closure of the algebra of the Dorfman derivative from section 2.
Appendix B contains a survey of decompositions of other algebras, most of which do
not give rise to geometries, but which complement the discussion in the main text.

2 $Spin(d, d) \times \mathbb{R}^+$ generalised geometry

$Spin(d, d) \times \mathbb{R}^+$ generalised geometry is the generalised geometry based upon the dia-
gram

```
E
```

As in the introduction, this indicates that the structure group of the geometry is
$Spin(d, d) \times \mathbb{R}^+$ and the fibre of the generalised tangent space is the fundamental repre-
sentation corresponding to the node labelled $E$, which is in this case one of the spinor
representations. This is very different to the $O(d, d)$ generalised geometry of [1, 2],
which would correspond to the diagram
though, due to $Spin(4,4)$ triality, the two geometries coincide for $d = 4$.

One instance of this geometry has appeared in the literature before, as the case $d = 5$ coincides with $E_{5(5)} \times \mathbb{R}^+$ generalised geometry \cite{4,12,24} which is relevant to eleven-dimensional supergravity on five-dimensional spaces. Here we will describe these geometries more generally, with particular interest in the case of $d = 8$, as this describes “half” of $E_{8(8)} \times \mathbb{R}^+$ in a way which will be described in section 3.

2.1 Algebraic decompositions under $GL(d, \mathbb{R})$

The first step in the analysis here is to look for the desired embedding of $GL(d, \mathbb{R})$ which gives a $(d - 2)$-form in the decomposition of the adjoint of $Spin(d,d)$. With the embedding of \cite{2}, one has:

$$\text{ad}(Spin(d,d)) \rightarrow (W \otimes W^*) \oplus \Lambda^2 W \oplus \Lambda^2 W^* \quad (2.1)$$

where $W$ is the standard representation of this $GL(d, \mathbb{R})$ subgroup. Consider setting

$$\Lambda^2 W = \Lambda^{(d-2)} T^* = \Lambda^d T^* \otimes \Lambda^2 T \quad (2.2)$$

where $T$ is also a fundamental representation of $GL(d, \mathbb{R})$ but with a different weight under the $\mathbb{R} \subset GL(d, \mathbb{R})$. This leads to the identification

$$W = (\Lambda^d T^*)^{\frac{1}{2}} \otimes T \quad (2.3)$$

We then have

$$\text{ad}(Spin(d,d)) \rightarrow (T \otimes T^*) \oplus \Lambda^{(d-2)} T \oplus \Lambda^{(d-2)} T^* \quad (2.4)$$

which is the desired decomposition. Henceforth, we will consider the $GL(d, \mathbb{R})$ subgroup which acts naturally on $T$ to be the one of relevance. This switching of choice of $GL(d, \mathbb{R})$ subgroup is essentially the reversal of the gravity line in the diagram. We note here that the parabolic subalgebra, which will correspond to the geometric subgroup in the context of generalised geometry, is spanned by the subspace

$$\text{ad}(GL(d, \mathbb{R})) \oplus \Lambda^{(d-2)} T^* \quad (2.5)$$

which corresponds to diffeomorphisms and gauge transformations in the physics.
As in \([3–5]\), this \(GL(d, \mathbb{R})\) subgroup will also intersect the \(\mathbb{R}^+\) factor in the full structure group \(\text{Spin}(d, d) \times \mathbb{R}^+\). We make the definition

\[
1_{+1} \simeq (\Lambda^d T^*)^{\frac{d-4}{4}}, \tag{2.6}
\]

the appropriateness of which will become apparent when we see that the generalised tangent space will have unit weight under the \(\mathbb{R}^+\) factor.

We now turn to the decomposition of the spinor representation which will be the fibre of the generalised tangent space. As the chirality of the spinor depends on whether \(d\) is odd or even, we treat these cases separately.

For \(d\) odd, the spinor has positive chirality. As in \([2]\), we have the decomposition of the weight zero, positive chirality spinor of \(\text{Spin}(d, d) \times \mathbb{R}^+\) as

\[
S_0^+ \to (\Lambda^d W)^{\frac{1}{2}} \otimes \left[\Lambda^\text{(even)} W^*\right] \tag{2.7}
\]

This leads to the decomposition of the weight one spinor \(S_{+1}^+ = S_0^+ \otimes 1_{+1}\)

\[
S_{+1}^+ \to T \oplus \Lambda^{(d-3)} T^* \oplus (\Lambda^d T^* \otimes \Lambda^{(d-5)} T^*) \oplus ((\Lambda^d T^*)^2 \otimes \Lambda^{(d-7)} T^*)
\]

\[
\oplus \cdots \oplus ((\Lambda^d T^*)^{(d-3)/2}) \tag{2.8}
\]

Conversely, for \(d\) even, the spinor has negative chirality. By similar means, we arrive at the decomposition of the weight one spinor \(S_{+1}^- = S_0^- \otimes 1_{+1}\)

\[
S_{+1}^- \to T \oplus \Lambda^{(d-3)} T^* \oplus (\Lambda^d T^* \otimes \Lambda^{(d-5)} T^*) \oplus ((\Lambda^d T^*)^2 \otimes \Lambda^{(d-7)} T^*)
\]

\[
\oplus \cdots \oplus ((\Lambda^d T^*)^{(d-4)/2} \otimes T^*) \tag{2.9}
\]

2.2 \(\text{Spin}(d, d) \times \mathbb{R}^+\) generalised tangent space and generalised tensors

One can now exactly follow through the construction of \([3–5]\) with these algebras and representations. One now thinks of \(T\) as the tangent bundle of a \(d\)-dimensional manifold and considers a generalised tangent space \(E\) as a bundle with a local isomorphism

\[
E \simeq T \oplus \Lambda^{(d-3)} T^* \oplus (\Lambda^d T^* \otimes \Lambda^{(d-5)} T^*) \oplus ((\Lambda^d T^*)^2 \otimes \Lambda^{(d-7)} T^*) \oplus \ldots \tag{2.10}
\]

on patches of the manifold. On the overlaps of patches, one has transition functions given by diffeomorphisms and gauge transformations, the action of the latter being the \(\text{Spin}(d, d) \times \mathbb{R}^+\) action of exponentiated exact \((d-2)\)-forms. The structure group of the generalised tangent bundle is thus the parabolic subgroup of \(\text{Spin}(d, d) \times \mathbb{R}^+\) generated by the subalgebra \(2.5\).

However, one can still construct a \(\text{Spin}(d, d) \times \mathbb{R}^+\) frame bundle, in the same way that an \(E_{d(d)} \times \mathbb{R}^+\) frame bundle was constructed in \([4]\). This is then a \(\text{Spin}(d, d) \times \mathbb{R}^+\)
principal bundle, which enables us to construct $\text{Spin}(d,d) \times \mathbb{R}^+$ vector bundles with any representation as the fibre. These are the generalised tensor bundles for the geometry.

A generic $\text{Spin}(d,d) \times \mathbb{R}^+$ frame $\{\hat{E}_\alpha\}$ carries a spinor index $\alpha = 1, \ldots, 2^d - 1$ and we can express a generalised vector as $V = V^\alpha \hat{E}_\alpha$. In even dimensions, $E^*$ has the representation $S_{-1}$ as its fibre, so one can write a dual basis with the same spinor index $\{E^{\hat{\alpha}}\}$. In odd dimensions, the fibre of $E^*$ is $S_{-1}$, which carries the other spinor index to that for $E$. The dual basis therefore is written as $\{\hat{E}_\dot{\alpha}\}$, where also $\dot{\alpha} = 1, \ldots, 2^d - 1$.

We will primarily focus on the example of $d = 8$ in this paper, so from now on for notational convenience we restrict focus to the case of $d$ even, though of course very similar statements also hold for the case of $d$ odd.

### 2.3 The Dorfman derivative and the bundle $N$

The Dorfman derivative by a generalised vector $V \in E$ can be defined using the definition of \[ L_V = \partial V - (\partial \times_{\text{ad}} V) \cdot, \] (2.11)

where, as usual in generalised geometry, the partial derivative is promoted to have an $E^*$ index using the embedding $T^* \rightarrow E^*$.

The symbol $\times_{\text{ad}}$ indicates the projection of the partial derivative of the components of $V$, which has the indices of $E^* \otimes E$, onto the adjoint of $\text{Spin}(d,d) \times \mathbb{R}^+$. This notation was introduced in [4]. One can see immediately that the Dorfman derivative will be covariant under diffeomorphisms by examining the $\text{GL}(d,\mathbb{R})$ decompositions of $E$ and $E^*$. Roughly, the Dorfman derivative is a combination of the Lie derivative along the $T$ direction in $E$ and the $\text{Spin}(d,d)$ action of the $(d-2)$-form $d\omega$, where $\omega$ is the $\Lambda^{d-3}T^*$ part of $V$. No other contributions to the second term of (2.11) are compatible with $\text{GL}(d,\mathbb{R})$.

The Dorfman derivative is most usefully written in spinor indices. Acting on another generalised vector $W = W^\alpha \hat{E}_\alpha$, we have\(^4\)

\[
(L_V W)^\alpha = V^\beta \partial_\beta W^\alpha + \frac{1}{8} (\sigma_{MN})^\gamma_\delta (\partial_\gamma V^\delta)(\sigma^{MN})^\alpha_\beta W_\beta + \frac{d-4}{4} (\partial_\beta V^\beta) W^\alpha \tag{2.12}
\]

where here the matrices $\sigma_{MN}$ are the generators of the $\text{Spin}(d,d)$ algebra acting on the spinors $V^\alpha$. For more details of our conventions, see appendix A.1. One can also act on other generalised tensors, for example a generalised tensor $X$ transforming in the vector representation of $\text{Spin}(d,d)$ with zero weight under $\mathbb{R}^+$. This Dorfman derivative can be written as

\[
(L_V X)^M = V^\alpha \partial_\alpha X^M + \frac{1}{2} (\sigma^{MN})^\alpha_\beta (\partial_\alpha V^\beta) X^N \tag{2.13}
\]

\(^4\)Recall that we are taking $d$ even here.
One can then study the closure of the algebra of the Dorfman derivative. To do this using the expressions with spinor indices above, one needs to make note of some combinations of two partial derivatives which vanish identically, due to the fact that only the components of $\partial_\alpha$ along $T^*$ are non-vanishing. In fact, studying the $GL(d, \mathbb{R})$ decompositions, one finds that only the irreducible parts
\[
(\sigma_{M_1\ldots M_{d-2}})^{[\alpha\beta]} \partial_\alpha(\ldots) \partial_\beta(\ldots)
\] and
\[
(\sigma_{M_1\ldots M_d})^{(\alpha\beta)} \partial_\alpha(\ldots) \partial_\beta(\ldots)
\] (2.14)
of two separate derivatives and, for second derivatives, only
\[
(\sigma_{M_1\ldots M_d})^{(\alpha\beta)} \partial_\alpha \partial_\beta(\ldots)
\] (2.15)
can be non-vanishing. The remaining irreducible parts of $S^2 E^*$ form the bundle $N^* \subset S^2 E^*$, the dual of which is of course $N$, the analogue of the bundle $N$ from [4]. The general description of this phenomenon can be found in appendix A.2.

Armed with (2.14) and (2.15), one can see the closure of the algebra using Fierz identities. Some of the steps of this derivation are highlighted in appendix A.3. In fact, the closure of the algebra is guaranteed by the results of [6], and the structure forms a Leibnitz algebroid.

### 2.4 Generalised connections and torsion

Generalised connections are defined simply as linear differential operators
\[
D : B \to E^* \otimes B
\] (2.16)
where $B$ is any $Spin(d, d) \times \mathbb{R}^+$ tensor bundle and the generalised torsion is defined for $V \in E$ by
\[
T(V) = L_V^{(D)} - L_V
\] (2.17)
acting on any generalised tensor.

Writing $D_\alpha = \partial_\alpha + \Omega_\alpha$, where $\Omega_\alpha$ is a local Lie algebra valued section of $E^*$, one can see that $\Omega$ has a decomposition into $Spin(d, d) \times \mathbb{R}^+$ irreducible parts
\[
S_{-1}^- \otimes \text{ad}(Spin(d, d) \times \mathbb{R}^+) = S_{-1}^- + S_{-1}^- + K_{-1} + P_{-1}
\] (2.18)
where $K$ is the representation corresponding to the positive chirality spin-$\frac{3}{2}$ representation.

From (2.12), one can easily see that the generalised torsion lives in the representations $S_{-1}^- \oplus K_{-1}$. The leading terms of the $GL(d, \mathbb{R})$ decomposition of this reads as
\[
S_{-1}^- \oplus K_{-1} \to T^* \oplus (T \otimes \Lambda^2 T^*) \oplus \Lambda^{d-1} T^* \oplus \ldots
\] (2.19)
so the generalised torsion contains the ordinary torsion as well as terms for a $(d-1)$-form flux and the derivative of a scalar.
2.5 Split frames and $\text{Spin}(d) \times \text{Spin}(d)$ structures

As in [3, 4], one can construct so-called conformal split frames for the geometry, essentially by acting on a local coordinate induced frame $\{\hat{\mathcal{E}}_a\} = \{\partial/\partial x^m, dx^m \wedge \cdots \wedge dx^{m-3}, \ldots\}$ with an element of the geometric subgroup, which untwists the patching of the generalised tangent space, and an $\mathbb{R}^+$ scaling. The key ingredient of this group element is a $(d-2)$-form gauge field which has the same gauge transformation patching as the twisting of the generalised tangent space. The split frames concretely realise the global isomorphism

$$E \simeq T \oplus \Lambda^{(d-3)}T^* \oplus (\Lambda^d T^* \otimes \Lambda^{(d-5)}T^*) \oplus \cdots \quad (2.20)$$

Now suppose we have a metric $g_{mn}$, a scalar field $\Delta$ and a $(d-2)$-form gauge field $A_{m_1 \ldots m_{d-2}}$. One can build a particular $SO(d)$ family of split frames corresponding to these fields, the $SO(d)$ family coming from the $SO(d)$ family of vielbeins $\hat{e}_a^m$ for the given metric.

In one of these special split frames $\{\hat{\mathcal{E}}_a\}$, one can define a positive definite inner product on $E$ by

$$G(V, V) = \delta_{ab} V^a V^b + \frac{1}{(d-3)!} \delta^{a_1 b_1} \cdots \delta^{a_{d-3} b_{d-3}} V_{a_1 \ldots a_{d-3}} V_{b_1 \ldots b_{d-3}} + \cdots \quad (2.21)$$

where $V = V^a \hat{\mathcal{E}}_a + \frac{1}{(d-3)!} V_{a_1 \ldots a_{d-3}} \hat{E}^{a_1 \ldots a_{d-3}} + \cdots$. This inner product is stabilised by $\text{Spin}(d) \times \text{Spin}(d)$, the maximal compact subgroup of $\text{Spin}(d,d) \times \mathbb{R}^+$, so the generalised vielbein frames for this generalised metric form a $\text{Spin}(d) \times \text{Spin}(d)$ structure.

Given this structure, one can then go through the remaining steps the construction of [3–5]. One finds a family of torsion-free compatible connections and a set of unique operators associated to them acting on certain spinor bundles of $\text{Spin}(d,d) \times \mathbb{R}^+$.

2.6 Appearance in supergravity

For small values of $d$, the $\text{Spin}(d,d) \times \mathbb{R}^+$ generalised geometries all appear in maximal supergravity. Here we give a brief discussion of some examples.

$d = 4$ and $d = 5$

As mentioned before, the $d = 4$ case coincides exactly with the original $O(4,4)$ generalised geometry of [1, 2], after a $\text{Spin}(4,4)$ triality rotation. One can see that the $\mathbb{R}^+$ weight of $E$ vanishes, as does the relevant term of the Dorfman derivative. The relevance of this geometry to type II theories is well-known [3, 7–10].

The $d = 5$ geometry is the $E_{5(5)} \times \mathbb{R}^+$ generalised geometry of eleven-dimensional supergravity restricted to five-dimensional spaces [4, 5, 12, 24].
This geometry can be viewed as a subsector of the $E_{7(7)} \times \mathbb{R}^+$ generalised geometry of type IIB supergravity restricted to six-dimensional spaces [4, 12, 15, 16]. The generalised tangent space has the decomposition

$$E \simeq T \oplus \Lambda^3 T^* \oplus (\Lambda^6 T^* \otimes T^*) \quad (2.22)$$

thus including the charges of the D3-brane and dual graviton. Note that no gauge transformation associated to the dual graviton is included in the geometry, so that there are no problems with covariance.

$d = 7$ and $d = 8$

The $d = 8$ case could be viewed as a subsector of an $E_{8(8)} \times \mathbb{R}^+$ generalised geometry for eleven-dimensional supergravity restricted to eight-dimensional manifolds, if such a geometry existed. In this sense, it geometrising a sector of eleven-dimensional supergravity not previously covered by any geometric construction. The generalised tangent space decomposes as

$$E \simeq T \oplus \Lambda^5 T^* \oplus (\Lambda^8 T^* \otimes \Lambda^3 T^*) \oplus (\Lambda^8 T^*)^2 \otimes T^* \quad (2.23)$$

The additional charges in the geometry are thus the M5-brane, a higher dual of the M5-brane [50] and a higher dual of the graviton (see appendix B.2). Again, the gauge transformations associated to the dual charges are not included here.

The $d = 7$ case corresponds to half of the IIA circle reduction of the $d = 8$ case. Here $E$ has the decomposition

$$E \simeq T \oplus \Lambda^4 T^* \oplus (\Lambda^7 T^* \otimes \Lambda^2 T^*) \oplus (\Lambda^7 T^*)^2 \quad (2.24)$$

so one has the D4-brane, a dual version of the NS5-brane, and also a higher dual of the D0-brane. One can visualise this reduction in Dynkin diagrams by folding up the node at the right end (as in B.1) and then truncating it.

### 3 Half-exceptional generalised geometry

In this section, we show how the $Spin(8,8) \times \mathbb{R}^+$ geometry of the previous section fits into a series of “half-exceptional” algebras we denote $E_d^{(1/2)}$, listed in table 1. These algebras are constructed by taking the level decompositions\(^{5}\) of the exceptional algebras and truncating to even levels only. As the grading respects this operation, the resulting

\(^{5}\)In the extra node added to the gravity line as in [49].
algebra is guaranteed to close. The Dynkin diagrams of the resulting series of algebras closely resemble those of the exceptional algebras, in that there is a gravity line with one node added. However, this node is now added above the sixth node from the right instead of the third. The $Spin(d, d) \times \mathbb{R}^+$ series of the previous section was built by adding nodes to the right end of the Dynkin diagram, which changed the relevant higher dimensional theory as well as the dimension of restriction. The present series adds nodes to the left end, which keeps the higher dimensional theory the same, while increasing the dimension of restriction.

\begin{table}[h]
\centering
\begin{tabular}{|c|c|c|c|}
\hline
$d$ & $E_d^{(1/2)} \times \mathbb{R}^+$ & $H_d^{(1/2)}$ & Dynkin diagram \\
\hline
6 & $SL(6, \mathbb{R}) \times SL(2, \mathbb{R}) \times \mathbb{R}^+$ & $SO(6) \times SO(2)$ & $E$
\hline
7 & $SL(8, \mathbb{R}) \times \mathbb{R}^+$ & $SO(8)$ & $E$
\hline
8 & $Spin(8, 8) \times \mathbb{R}^+$ & $Spin(8) \times Spin(8)$ & $E$
\hline
9 & $E_{9(9)}$ & $KE_{9(9)}$ & $E$
\hline
\end{tabular}
\caption{Series of half-exceptional groups and their maximal compact subgroups}
\end{table}

The representation corresponding to the generalised tangent space is given by a Dynkin label with a 1 for the nodes labelled $E$ and zero for the other nodes. This overall pattern is exactly as for the exceptional groups. Note that though we added $E_{9(9)}$ in the last line to continue the algebraic pattern, we do not discuss this group further in this paper.

For the supergravity, the truncation to even levels means that one restricts to a subsector of the field content. The full exceptional algebra is generated by the $\Lambda^3T \oplus \Lambda^3T^*$ part of the algebra and multiple commutators. This roughly corresponds to the presence of the three-form gauge field $A_{(3)}$ in the supergravity. In the same way, the truncation to even levels is generated instead by the $\Lambda^6T \oplus \Lambda^6T^*$ part, which corresponds
to the six-form $\tilde{A}_{(6)}$. Therefore, it makes perfect sense that these algebras geometrise the subsector consisting of the metric, the six-form and, as the dimension increases, their higher rank dual fields (in the sense of [50]).

### 3.1 Half-exceptional geometry for $d \leq 7$

The complete description of the half-exceptional geometries for $d \leq 7$ can almost be read-off from the equations in [4, 5], simply by setting the truncated terms to zero. For example the generalised tangent space has a local isomorphism

$$E \simeq T \oplus \Lambda^5 T^*,$$

(3.1)

the Dorfman derivative becomes

$$L_V V' = \mathcal{L}_v v' + (\mathcal{L}_v \sigma' - i_v d\sigma)$$

(3.2)

where $v \in T$ and $\sigma \in \Lambda^5 T^*$ are the two parts of the generalised vector $V$, and the generalised torsion acts as

$$T(V) = e^{\Delta} \left( -i_v d\Delta + v \otimes d\Delta - i_v \tilde{F} + d\Delta \wedge \sigma \right).$$

(3.3)

The $N$ bundle decomposes as

$$N \simeq \Lambda^4 T^* M \oplus (\Lambda^7 T^* M \otimes \Lambda^3 T^* M).$$

(3.4)

so that the corresponding representation is the fundamental representation for the fourth node from the right of the Dynkin diagram. See [4] for precise details of the meaning of these expressions.

The maximal compact subgroup $H_d \subset E_{d(d)} \times \mathbb{R}^+$ becomes now the maximal compact subgroup $H_d^{(1/2)}$ of $E_d^{(1/2)} \times \mathbb{R}^+$ as listed in table 1, which is a subgroup of $H_d$ with algebra

$$\text{ad}(H_d^{(1/2)}) \simeq \Lambda^2 T^* \oplus \Lambda^6 T^*,$$

(3.5)

under an $SO(d)$ decomposition. The representations of $H_d$ in which the fermions transform then decompose under $H_d^{(1/2)}$, but one need not decompose them in order to do calculations. In fact, it is more convenient not to. Note however that there is one substantial simplification in truncating away the $\Lambda^3 T^*$ component of the $H_d$ algebra: we no longer need to consider the two different representations of the algebra on the fermions, which were distinguished by the sign of the action of $\Lambda^3 T^*$ [5].

The only equation which must be changed is the expression for the torsion-free compatible connection in the split frame. The expression given in [4] is a particular
choice, as the result is ambiguous up to the undetermined parts of the connection. This
particular choice is no longer available to us in the more restricted setup considered
here, so we must instead write

\[
D_a = e^\Delta \left( \nabla_a + \frac{1}{4} \left( \frac{d+2}{d-1} \right) \partial_b \Delta \gamma_a^b - \frac{1}{2} \frac{1}{d!} F_{ab_1...b_6} \gamma^{b_1...b_6} + Q_a \right),
\]

\[
D^{a_1...a_5} = e^\Delta \left( \frac{3}{4} \gamma^{a_1...a_5}_{b_1 b_2} \gamma^{b_1 b_2} - \frac{3}{4} \left( d-1 \right)^{-1} \partial_b \Delta \gamma^{b a_1...a_5} + \frac{Q^{a_1...a_5}}{Q} \right),
\]

where again \(Q\) represents the parts of the connection which are not determined uniquely.

The unique derivative operators which led to the supersymmetry variations of the
fermions in [5] can also be truncated straightforwardly. We reproduce here the relevant
terms acting on a spinor \(\tilde{\epsilon} = e^{-\Delta/2} \epsilon^{\text{sugra}}\), which is promoted to a representation of \(H^{(1/2)}_d\)

\[
\bar{D} \tilde{\epsilon} = \Gamma^a D_a \tilde{\epsilon} + \frac{1}{d!} \Gamma^{c_1...c_5} D_{c_1...c_5} \tilde{\epsilon}
= e^{\Delta/2} \left( \nabla_a + \frac{9-d}{2} \partial_a \Delta \right) \tilde{\epsilon}^{\text{sugra}},
\]

\[
(D \wedge \tilde{\epsilon})_a = D_a \tilde{\epsilon} - \frac{3}{2} \frac{1}{d!} \Gamma^{c_1...c_4} D_{ac_1...c_4} \tilde{\epsilon} + \frac{2}{3} \frac{1}{d!} \Gamma_a^{c_1...c_5} D_{c_1...c_5} \tilde{\epsilon}
= e^{\Delta/2} \left( \nabla_a - \frac{3}{2} \frac{1}{d!} F_{ab_1...b_6} \Gamma^{b_1...b_6} \epsilon \right) \tilde{\epsilon}^{\text{sugra}}.
\]

We briefly note that the \(d = 7\) case here is part of a family of generalised geometries
based on the groups \(SL(d+1, \mathbb{R}) \times \mathbb{R}^+\), with diagrams

This family is similar to that of section 2, but it geometrises a \((d - 1)\)-form potential,
leading to a top-form field strength. Another example of this series is the well-known
\(E_4(4) \times \mathbb{R}^+\) generalised geometry in four dimensions studied in [4, 5, 12, 23]. They can
be thought of as the “gravity-line-reversal” of the geometry in appendix B.1.

### 3.2 Half-exceptional geometry for \(d = 8\): Spin\((8, 8) \times \mathbb{R}^+\)

The \(GL(8, \mathbb{R})\) decompositions of the relevant representations of \(E_{8(8)} \times \mathbb{R}^+\) read

\[
1_{+1} \to (\Lambda^8T^*)
\]

\[
248_0 \to (T \otimes T^*) \oplus \Lambda^3T \oplus \Lambda^3T^* \oplus \Lambda^6T \oplus \Lambda^6T^*
\]

\[
248_{+1} \cong 248_0 \otimes 1_{-1}
\]

\[
\to T \oplus \Lambda^2T^* \oplus \Lambda^5T^* \oplus (T^* \otimes \Lambda^7T^*)
\]

\[
\oplus (\Lambda^8T^* \otimes \Lambda^3T^*) \oplus (\Lambda^8T^* \otimes \Lambda^6T^*) \oplus ((\Lambda^8T^*)^2 \otimes T^*)
\]

\[\text{– 14 –}\]
Performing the truncation to even levels on $E_8(8) \times \mathbb{R}^+$, one is left with the $\text{Spin}(8, 8) \times \mathbb{R}^+$ subgroup. The geometry we need is thus the $\text{Spin}(8, 8) \times \mathbb{R}^+$ geometry of the previous section.

The decompositions listed there provide us with the generalised tangent space and the adjoint bundle associated to the frame bundle. We now look at the decompositions of the bundle $N$ and the torsion representation $K_{-1}$. The fibre of $N$ is the representation $1_{+2} \oplus 1820_{+2}$, so that

$$N \simeq (\Lambda^8 T^*)^2 \oplus \Lambda^4 T^* \oplus (\Lambda^7 T^* \otimes \Lambda^3 T^*) \oplus (\Lambda^8 T^* \otimes \Lambda^2 T^* \otimes \Lambda^6 T^*)$$

$$\oplus ((\Lambda^8 T^*)^2 \otimes T^* \otimes \Lambda^5 T^*) \oplus ((\Lambda^8 T^*)^3 \otimes \Lambda^4 T^*) \quad (3.9)$$

Note that in order for an expression of the form $L_V W + L_W V = \partial \times_E (V \times_N W)$ to exist, one would need a coordinate independent map

$$\partial : (\Lambda^8 T^*)^2 \to (\Lambda^8 T^*)^2 \otimes T^* \quad (3.10)$$

which clearly cannot be canonically defined. Therefore, as for the $E_7(7) \times \mathbb{R}^+$ geometry of [4], no such expression can be written.

The fibre of $K_{-1}$ is the spin-$\frac{3}{2}$ representation $1920^+_{-1}$, giving a decomposition

$$K \simeq (T \otimes \Lambda^2 T^*) \oplus \Lambda^7 T^*$$

$$\oplus (T \otimes \Lambda^4 T^*)^0 \oplus (T^* \otimes \Lambda^6 T) \oplus (\Lambda^7 T \otimes \Lambda^4 T)$$

$$\oplus (\Lambda^8 T \otimes T \otimes \Lambda^2 T^*)^0 \oplus (\Lambda^8 T \otimes \Lambda^2 T \otimes \Lambda^7 T) \oplus ((\Lambda^8 T)^2 \otimes \Lambda^7 T) \quad (3.11)$$

At first glance some of the terms here which survive in $d \leq 7$ appear to disagree with those given in [4]. However, on using the seven-dimensional isomorphism $T^* \otimes \Lambda^6 T = \Lambda^7 T \otimes T^* \otimes T^* = \Lambda^5 T \oplus (\Lambda^7 T \otimes S^2 T^*)$, one can see that there is no contradiction.

The expressions for the torsion-free compatible connection and unique projections for the SUSY variations for $d \leq 7$ extend to the case $d = 8$ without the need for significant modification. Here there are more parts of the connection to deal with, but we can choose to express the connection (acting on a spinor $\hat{\epsilon} = e^{-\Delta/2} \hat{\epsilon}^{\text{sugra}}$) as

$$D_a = e^\Delta \left( \nabla_a + \frac{1}{4} (\frac{17}{2} - 2d) (\partial_b \Delta) \gamma^b_a - \frac{1}{2} \frac{1}{7!} \bar{F}_{a b_1 \ldots b_6} \gamma^{b_1 \ldots b_6} + Q_a \right),$$

$$D^{a_1 \ldots a_2} = e^\Delta \left( \frac{1}{4} \bar{F}^{a_1 \ldots a_2} \gamma^{b_1 b_2} - \frac{3}{5} \frac{1}{4} \frac{1}{4} (\tilde{\partial}_b \Delta) \gamma^{b_1 \ldots b_5 a_1 \ldots a_2} + Q^{a_1 \ldots a_2} \right),$$

$$D^{(\ldots)} = e^\Delta \left( Q^{(\ldots)} \right), \quad \text{for other parts} \quad (3.12)$$
so that these terms do not affect the calculation of the projection

\[
\mathcal{P}\hat{\epsilon} = \Gamma^{a}D_{a}\hat{\epsilon} + \frac{1}{3!}\Gamma^{c_{1}...c_{5}}D_{c_{1}...c_{5}}\hat{\epsilon} + (\ldots)
\]

\[
= e^{\Delta/2}\left(\nabla + \frac{g-d}{2}(\bar{\phi}\Delta) - \frac{1}{4}\bar{F}\right)\varepsilon^{\text{supra}},
\]

\[
(D \land \hat{\epsilon})_{a} = D_{a}\hat{\epsilon} - \frac{1}{3!}\Gamma^{c_{1}...c_{4}}D_{ac_{1}...c_{4}}\hat{\epsilon} + \frac{2}{3}\Gamma^{a}_{c_{1}...c_{5}}D_{c_{1}...c_{5}}\hat{\epsilon} + (\ldots)
\]

\[
= e^{\Delta/2}\left(\nabla_{a} + \frac{1}{6!}\tilde{F}_{b_{1}...b_{7}}\Gamma_{a}^{b_{1}...b_{7}}\varepsilon - \frac{1}{12!}\tilde{F}_{ab_{1}...b_{6}}\Gamma^{b_{1}...b_{6}}\varepsilon\right)\varepsilon^{\text{supra}}.
\]

as the undetermined pieces of the connection \(Q\) cancel.

### 3.3 Supersymmetry variations with only \(\tilde{F}_{(7)}\)

The supersymmetry variation of the eleven-dimensional gravitino can be written in terms of the dual field strength \(*F = *dA_{(3)}\) as

\[
\delta\psi_{M} = \nabla_{M}\varepsilon + \frac{1}{12}\left[\frac{2}{7!}(\ast F)_{N_{1}...N_{7}}\Gamma_{M}^{N_{1}...N_{7}} - \frac{1}{6!}(\ast F)_{MN_{1}...N_{6}}\Gamma^{N_{1}...N_{6}}\right] \varepsilon
\]

Using the ansatz

\[
\tilde{F}_{m_{1}...m_{7}} = \ast F_{m_{1}...m_{7}} \quad \ast F_{\mu M_{1}...M_{6}} = 0
\]

but otherwise keeping the same reduction of fields as in [5], this gives rise to the supersymmetry variations

\[
\delta\rho = \left[\nabla - \frac{1}{3}\tilde{F} + \frac{g-d}{2}(\bar{\phi}\Delta)\right]\varepsilon,
\]

\[
\delta\psi_{m} = \left[\nabla_{m} + \frac{1}{6!}\tilde{F}_{n_{1}...n_{7}}\Gamma_{m}^{n_{1}...n_{7}} - \frac{1}{12!}\tilde{F}_{mn_{1}...n_{6}}\Gamma^{n_{1}...n_{6}}\right] \varepsilon,
\]

for the fermions in the \(d\)-dimensional restriction.

These are precisely the expressions reproduced by the projection operators (3.13) in the half-exceptional geometry. The generalised geometry description of supersymmetric backgrounds [7, 15, 17, 55] can therefore be extended to the case of compactifications to three dimensions with only internal \(*F\) fluxes by the \(Spin(8, 8) \times \mathbb{R}^{+}\) geometry. Some work examining such backgrounds (as well as more general cases) was presented in [56].

From this point, one anticipates that the rest of the construction will go through, exactly as in [4, 5], to provide all of the equations of this restricted theory.

### 4 Discussion

In this paper, we have constructed a new family of generalised geometries based on the groups \(Spin(d, d) \times \mathbb{R}^{+}\) in which the generalised tangent space corresponds to a spinor representation of the group. We have shown how these geometries arise in supergravity
and how the case of $Spin(8, 8) \times \mathbb{R}^+$ provides a geometry for a class of supersymmetric backgrounds which fall outside the classes covered previously.

The idea of studying geometries containing subsectors of the field content of a theory is not new, as the original generalised geometry of $[1, 2]$ covered only the NS-NS sector of type II supergravity. This can be viewed as taking an $O(10, 10) \times \mathbb{R}^+$ subgroup of $E_{11}$ [57]. In a sense, the construction of $[4, 5]$ also contains only a subsector as there the fields are dimensionally restricted. Recently the main focus has been to try to include all of the fields, in increasing dimensions. However, one quickly runs into serious problems even for $E_{8(8)} \times \mathbb{R}^+$, related to the problem of dual gravity, and worse still for the infinite-dimensional algebras conjectured to underlie the cases where yet more dimensions are included, as there are then infinitely many mixed symmetry tensor fields to account for.

While understanding this is obviously an important ultimate goal, it may be worthwhile to study subsectors where the problems associated to these more complicated types of fields do not appear. It seems likely that the $Spin(d, d) \times \mathbb{R}^+$ series will continue to have some role as one includes more dimensions of the eleven-dimensional theory in the geometry. For the case of $Spin(8, 8)$ we have found that the geometric prescription appears to hold good if one simply truncates away the problematic fields. The generalised tangent space still contains the higher level charges, though they do not actively play a role. It seems likely that this pattern will continue. The $Spin(9, 9)$ case contains a six-form charge, which may well be the D6 brane of type IIA restricted to 8 dimensions. More interesting could be the $Spin(10, 10)$ case with a seven-form charge, which could be related to one of the three seven-branes in type IIB [58]. The $Spin(11, 11)$ case has an eight-form charge, which may be the totally anti-symmetric part of the dual graviton in the full eleven-dimensions. These cases all deserve some investigation in the future.

The other respect in which it may be useful to consider subsectors is for the study of supersymmetric backgrounds. Clearly, one need not always have all fluxes switched on, so for the purposes of considering backgrounds with only certain fluxes, the calculations are vastly simplified if one includes only the relevant fluxes in the geometry.

The investigations of appendix B.5 indicate that dimensional restrictions of six-dimensional minimal supergravity can also be described by generalised geometry. Further, one can include vector and tensor multiplets in six dimensions, provided the restricted fields parameterise a coset. One encounters the same problems as for $E_{8(8)} \times \mathbb{R}^+$ if one tries to include three dimensions or more, but the restrictions to two dimensions appear to work as for $E_{d(d)} \times \mathbb{R}^+$ for $d \leq 7$ in eleven-dimensional supergravity. One can similarly consider $G_{2(2)} \times \mathbb{R}^+$ for five-dimensional minimal supergravity restricted to two dimensions and find a similar situation to the $SO(4, 3) \times \mathbb{R}^+$ case of B.5. This sug-
gests that the construction applies to any supergravity theory, so long as the restricted fields parameterise a coset and mixed symmetry tensor fields are not included.

Another overriding question, which we do not attempt to answer here, is what feature of these physical theories causes the appearance of generalised geometry? One could suspect the supersymmetry in supergravity may have a role here, as it seems to be very interwoven in the construction. However, generalised geometry also seems to be applicable in cases with no supersymmetry, and in the case of subsectors it is not clear that the fields considered form supermultiplets, so one can question whether one really has supersymmetry in those cases. Gravity may actually be the only absolutely common ingredient. The answer to this question will hopefully become clearer as more is known about these structures.

Acknowledgments

We would like to thank Daniel Waldram for many helpful discussions. This work was supported by the German Science Foundation (DFG) under the Collaborative Research Center (SFB) 676 “Particles, Strings and the Early Universe”.

A Conventions and technical details

A.1 Conventions

All convention choices whose relevance overlaps with those made in [4, 5] are chosen to match [4, 5].

We use indices $M, N, \cdots = 1, \ldots, 2d$ as the vector indices of $Spin(d,d)$ and spinor indices $\alpha, \beta, \cdots = 1, \ldots, 2d$. The generators $\omega_{MN}$ of $Spin(d,d)$ are taken to acts on vectors and spinors of $Spin(d,d)$ by

$$\delta X^M = \omega^M_{\ N} X^N \quad \delta V^\alpha = \frac{1}{4} \omega_{MN} (\sigma^{MN})^\alpha_\beta V^\beta$$

(A.1)

Where we have spinor inner products given by a real matrix $C_{\alpha\beta}$ below, we use the index conventions

$$C^{\alpha\beta} = (C^{-1})^{\alpha\beta} \quad V^\alpha = C^{\alpha\beta} V_\beta \quad V_\alpha = C_{\alpha\beta} V^\beta$$

(A.2)

The contraction of a $Spin(d,d) \times \mathbb{R}^+$ generalised vector $V = V^\alpha \hat{E}_\alpha$ with a generalised dual vector $Z = Z_\alpha E^\alpha$ is defined as $V^\alpha Z_\alpha$. The embeddings are normalised such that if $V$ and $W$ have only vector and one-form parts respectively, then $V^\alpha Z_\alpha = V^m Z_m$. 

− 18 −
A.2 Section conditions from Dynkin labels

As in the introduction, we order the Dynkin labels so that the first \((d - 1)\) places represent the gravity line, while the others correspond to the added nodes, separating the two groups with a semi-colon. The generalised tangent space \(E\) then always has a label \([1, 0, \ldots, 0; \ast]\).

We can then examine the decomposition of the tensor product of two such representations. We find there is always a term with a label \([2, 0, \ldots, 0; \ast]\) in the decomposition of the symmetric part \(S^2E\), while there is always one of the type \([0, 1, 0, \ldots, 0; \ast]\) in the antisymmetric part \(\Lambda^2E\). Looking at the \(GL(d, \mathbb{R})\) decomposition of \(E\), we see that there can only be one term like \(S^2T\) in \(S^2E\) and only one term like \(\Lambda^2T\) in \(\Lambda^2E\). These are always found in the decompositions of the representations with the labels just highlighted. Therefore, if we have two generalised vectors \(V\) and \(W\) living only in the \(T\) part of \(E\), then, since \(T \otimes T = S^2T \oplus \Lambda^2T\), only these irreducible parts of \(V \otimes W\) can be non-zero. The bundle labelled \(N\) in [4] therefore therefore corresponds to the complement of the representation with label \([2, 0, \ldots, 0; \ast]\) in \(S^2E\).

Considering instead \(E^* \simeq T^* \oplus \ldots\), one can consider the implications of the above for the partial derivative, which lives only in the \(T^*\) component. This allows one to quickly read off which combinations of two partial derivatives must vanish identically. There are two cases of interest.

If both derivatives act on the same object, clearly the antisymmetrised part will vanish. Of the symmetric part, only the irreducible component corresponding to the dual of the \([2, 0, \ldots, 0; \ast]\) representation defined above can survive.

If the derivatives act on different objects, then the same component of the symmetric part will survive as for the previous case. However, also only one irreducible component of the antisymmetric part can be non-vanishing: that corresponding to the dual of the \([0, 1, 0, \ldots, 0; \ast]\) representation defined above. Note that the presence of antisymmetrised derivatives acting on different objects vanishing identically has not been discussed prominently in the literature. This is because in most cases examined so far, the antisymmetric tensor product \(\Lambda^2E\) has been irreducible.

One can also see in the examples of appendix B that the leading \(GL(d, \mathbb{R})\) irreducible components of the bundle \(N\) have Dynkin labels which match the gravity line part of the Dynkin label for the containing representation of the enlarged algebra. For example, for the \(d \leq 7\) geometries in [4], the leading component is always \(T^*\), while for the \(d \leq 7\) half-exceptional cases of section 3 it is always \(\Lambda^4T^*\). These are also fairly easy to guess, given the form of \(E\).

These pneumonics provide an easy way to find the representation for the bundle \(N\), or rather its compliment in \(S^2E\). It seems likely that there is a similar extension of
them to find the entire sequence of representations discussed in [27], which are related to the tensor hierarchy [39].

A.3 Closure of Spin($d, d$) × $\mathbb{R}^+$ Dorfman algebra and Fierz identities

We examine the algebra of two Dorfman derivatives by $U, V \in E$ acting on $X$ as in (2.13). The interesting point is to see how projections of the partial derivatives have to vanish in order for the terms like $V(\partial U)(\partial X)$ and $VX(\partial U)$ to cancel. The former types of terms appear in \[(L_U, L_V) - L_{[U,V]}X\] as

\[
\left( -\frac{1}{2} \left[ \frac{1}{8} (\sigma^{PQ})^\alpha_\beta (\sigma_{PQ})^{\gamma_\delta} + \delta^\alpha_\delta \delta^{\gamma_\delta} + \frac{d-4}{4} \delta^\alpha_\delta \delta^{\gamma_\delta} \right] V^\beta (\partial_\gamma U^\delta) (\partial_\alpha X_M) \right) - (U \leftrightarrow V)
\]

while the latter appear as

\[
\left( -\frac{1}{4} (\sigma_{MN})^\alpha_\beta \left[ \frac{1}{8} (\sigma^{PQ})^\beta_\epsilon (\sigma_{PQ})^{\gamma_\delta} + \delta^\beta_\delta \delta^{\gamma_\delta} \delta^\epsilon_\gamma \right] (\partial_\alpha \partial_\beta U^\delta) V^\epsilon X^N \right) - (U \leftrightarrow V)
\]

One then applies the Fierz identities detailed below, which show a clear pattern. For the resulting expressions to vanish, one needs that the expressions

\[(\sigma^{M_1...M_p})^{\alpha_\beta} \partial_{\alpha}(... \partial_{\beta}(...)) \quad \text{and} \quad (\sigma^{M_1...M_q})^{\alpha_\beta} \partial_{\alpha} \partial_{\beta}(...)\]

are non-vanishing only for $p = d - 2$ or $p = d$ and $q = d$ respectively. One can see that this is indeed the case by evaluating the decompositions of the relevant representations of Spin($d, d$) × $\mathbb{R}^+$ under GL($d, \mathbb{R}$). Alternatively, one can apply the reasoning of appendix A.2.

**Fierz identity for Spin(4, 4)**

Here we have a symmetric spinor inner product $C_{(\alpha\beta)}$ on 8-component spinors ($\delta^\alpha_\alpha = 8$). We find

\[
\frac{1}{8} (\sigma^{MN})^\alpha_\beta (\sigma_{MN})^{\gamma_\delta} + \delta^\alpha_\delta \delta^{\gamma_\delta} + \frac{d-4}{4} \delta^\alpha_\delta \delta^{\gamma_\delta} = \frac{1}{8} \left[ 8C^{\alpha\gamma} C_{\beta\delta} \right]
\]

**Fierz identity for Spin(6, 6)**

Here the inner product $C_{[\alpha\beta]}$ is antisymmetric on 32-component spinors and we have

\[
\frac{1}{8} (\sigma^{MN})^\alpha_\beta (\sigma_{MN})^{\gamma_\delta} + \delta^\alpha_\delta \delta^{\gamma_\delta} + \frac{d-4}{4} \delta^\alpha_\delta \delta^{\gamma_\delta} = \frac{1}{32} \left[ -16C^{\alpha\gamma} C_{\beta\delta} + \frac{8}{21} (\sigma^{MN})^{\alpha\gamma} (\sigma_{MN})_{\beta\delta} \right]
\]
Fierz identity for $Spin(8, 8)$

$C_{(\alpha\beta)}$ is symmetric again and we have 128-component spinors. We obtain

$$
\frac{1}{8}(\sigma^{MN})^\alpha_\beta(\sigma_{MN})^\gamma_\delta + \delta^\alpha_\delta \delta^\gamma_\beta + \frac{d-1}{4} \delta^\alpha_\beta \delta^\gamma_\delta = \frac{1}{128} \left[ 32 C^{\alpha\gamma} C_{\beta\delta} + \frac{16}{2!} (\sigma^{MN})^{\alpha\gamma}(\sigma_{MN})_{\beta\delta} + \frac{8}{4!} (\sigma^{M_1...M_4})^{\alpha\gamma}(\sigma_{M_1...M_4})_{\beta\delta} \right]
$$

(A.8)

B Examples of algebras and $GL(d, \mathbb{R})$ decompositions

In this appendix we review the gravity line decompositions of some algebras relevant to restrictions of various gravitational theories. We include this to make contact with the discussion in the main text. We will endeavour to point out the references to the literature along the way, and it should be understood that the relevance of these algebras to the physical theories is not new. An important reference for much of the section is [34].

B.1 $SL(d+1, \mathbb{R}) \times \mathbb{R}^+$ and Kaluza-Klein reduction

The most trivial example of an algebra leading to a generalised geometry is $SL(d+1, \mathbb{R}) \times \mathbb{R}^+$ with diagram

```
  o---o   o---o
     E
```

One finds that

$$
E \simeq T \oplus \mathbb{R}
$$

(B.1)

and

$$
\text{ad}(SL(d+1, \mathbb{R}) \times \mathbb{R}^+) \simeq \mathbb{R} \oplus (T \otimes T^*) \oplus T \oplus T^*
$$

(B.2)

This corresponds to $(d+1)$-dimensional gravity restricted to $d$ dimensions. The geometry includes the $d$-dimensional gravity, 1-form gauge field and a scalar. It is clearly very reminiscent of ordinary Kaluza-Klein reduction. When written in $SL(d+1, \mathbb{R})$ indices, the form of the Dorfman derivative coincides with the ordinary Lie derivative.

The diagram above represents that of ordinary gravity, but with the right-most node “folded-up” off the gravity line. The pattern can be used fairly generally to examine the $S^1$ reduction of the parent higher dimensional theory. We will see it again below.

A further comment is that the $SL(d+1, \mathbb{R}) \times \mathbb{R}^+$ geometry described in section 3 is essentially the “gravity-line-reversal” of this one.
We examine pure $D$ dimensional gravity restricted to $d = D - 3$ dimensions (with a warp factor in the metric ansatz). This structure will appear as a subsector in almost all of the rest of the algebras considered in this appendix, so it is natural to study this first.

The relevant algebra is the algebra of the Ehlers group $SL(d + 1, \mathbb{R}) \times \mathbb{R}^+$. We draw the Dynkin diagram as

```
   \( d \)  
E \bigcirc \bigcirc \bigcirc \bigcirc \bigcirc (d - 1)
1 2 3 (d - 2)
```

the numbers indicating the order of the Dynkin labels, which we write as \([n_1, \ldots, n_{d-1}; n_d]\).

Now we look at the $GL(d, \mathbb{R})$ decompositions. Similarly to section 2.1, we use a different embedding to the one that immediately comes to mind. This leads to

$$
\text{ad}(SL(d + 1, \mathbb{R}) \times \mathbb{R}^+) \simeq \mathbb{R} \oplus (T \otimes T^*) \oplus (T \otimes \Lambda^d T) \oplus (T^* \otimes \Lambda^d T^*) \quad (B.3)
$$

We can identify here that the gauge field for the dual graviton living in $T^* \otimes \Lambda^d T^*$, which is not a pure differential form. Now let $(1_{+1} \simeq \Lambda^d T^*)$ and we have

$$
E \simeq ([1, 0, \ldots, 0; 1]_{+1} \simeq T \oplus (T^* \otimes \Lambda^{d-1} T^*) \oplus ((\Lambda^d T^*)^2 \otimes T^*) \quad (B.4)
$$

The dual graviton charge is thus $T^* \otimes \Lambda^{d-1} T^*$, and we also see here a higher dual charge $(\Lambda^d T^*)^2 \otimes T^*$, which must also result from pure gravity as that is all we have in this construction.

Now we examine

$$
S^2 E \simeq 1_{+2} \oplus [1, 0, \ldots, 0; 1]_{+2} \oplus [0, 1, 0, \ldots, 0, 1; 0]_{+2} \oplus [2, 0, \ldots, 0; 2]_{+2} \quad (B.5)
$$

and

$$
\Lambda^2 E \simeq [1, 0, \ldots, 0; 1]_{+2} \oplus [2, 0, \ldots, 0, 1; 0]_{+2} \oplus [0, 1, 0, \ldots, 0; 2]_{+2} \quad (B.6)
$$

We see that $S^2 E$ has one term of the form $[2, 0, \ldots, 0; *]$ while $\Lambda^2 E$ has a term like $[0, 1, 0, \ldots, 0; *]$. Applying the reasoning of A.2 we have

$$
N \simeq 1_{+2} \oplus [1, 0, \ldots, 0; 1]_{+2} \oplus [0, 1, 0, \ldots, 0, 1; 0]_{+2} \subset S^2 E \quad (B.7)
$$

Looking at leading terms

$$
[1, 0, \ldots, 0; 1]_{+2} \sim \Lambda^{d-1} T^* \oplus \ldots
$$

$$
[0, 1, 0, \ldots, 0, 1; 0]_{+2} \sim (T^* \otimes \Lambda^{d-2} T^*)^0 \oplus \ldots \quad (B.8)
$$
we see that $N \simeq (T^* \otimes \Lambda^{d-2}T^*) \oplus (\Lambda^dT^*)^2 \oplus \ldots$ looks to have the correct form under $GL(d, \mathbb{R})$ for there to be a gauge transformation of $E$ of the form

$$\partial : N \to E$$

(B.9)

as one would hope. However, this fails to be covariant as for the $d = 7$ case of $[4]$. The natural guess for the “torsion” representation is $E^* \oplus K \subset E^* \otimes \text{ad}[SL(d + 1, \mathbb{R}) \times \mathbb{R}]$ where $K \sim 1 \oplus [1, 0, \ldots, 0, 1] \oplus [0, 1, 0, \ldots, 0, 1, 0]$. The decompositions are

$$[1, 0, \ldots, 0, 1] \simeq T^* \oplus (T \otimes \Lambda^{d-1}T) \oplus ((\Lambda^dT)^2 \otimes T)$$

$$[0, 1, 0, \ldots, 0, 1, 0] \simeq (T \otimes \Lambda^2T^*)^0 \oplus (T \otimes \Lambda^{d-1}T)$$

$$\oplus (\Lambda^dT \otimes \Lambda^2T^*)^0 \oplus (\Lambda^dT)^2 \otimes \Lambda^2T \otimes T^*)^0$$

so that the overall “torsion” would be

$$E^* \oplus K \simeq T^* \oplus (T \otimes \Lambda^2T^*) \oplus 2 \times (T \otimes \Lambda^{d-1}T) \oplus \Lambda^dT \oplus (\Lambda^dT \otimes \Lambda^2T \otimes \Lambda^2T^*)$$

$$\oplus ((\Lambda^dT)^2 \otimes T) \oplus ((\Lambda^dT)^2 \otimes \Lambda^2T \otimes T^*)$$

(B.10)

However, even ignoring issues of covariance, the usual form (2.11) of the Dorfman derivative and torsion (2.17) fails to project out some parts of the connection. Therefore, it would seem that the prescription of $[3–5]$ would need some algebraic modification to include dual gravity. An interesting approach to this modification can be found in $[38]$.

A final comment here is that the restriction to $d = D - 2$ dimensions would involve the (centrally extended) affine algebra of $[59]$ with diagram

```
\begin{tikzpicture}
  \node (E) at (0,0) {$E$};
  \node (1) at (-1.5,-1) {$1$};
  \node (d) at (1.5,-1) {$(d-1)$};
  \draw (E) -- (1); \draw (E) -- (d);
  \draw (1) -- (d);
\end{tikzpicture}
```

This fits the pattern of the non-gravity line node connecting to those nodes of the gravity line corresponding to the potential term $(T^* \otimes \Lambda^{d-1}T^*$ in this case).

### B.3 Kaluza-Klein reduction of dual gravity

Consider the setup of B.2 with $D = 11$ and $d = 8$, which is a subsector of eleven-dimensional supergravity restricted to eight-dimensions we will see below. We wish to look at the reduction to type IIA, which corresponds to folding up the right-most node
of the Dynkin diagram as in B.1. This leads to the following $GL(7, \mathbb{R})$ decomposition for the remaining nodes of the gravity line

$$E \simeq T \oplus \mathbb{R} \oplus \Lambda^6 T^* \oplus \Lambda^7 T^*$$

$$\oplus (\Lambda^7 T^* \otimes (\Lambda^7 T^* \oplus T^*))$$

$$\oplus (T^* \otimes \Lambda^6 T^*) \oplus ((\Lambda^7 T^*)^2 \otimes T^*)$$

(B.12)

In the usual type IIA language, we see terms for the D0 and D6-branes on the first line and the dual gravity setup of B.2. The $\Lambda^7 T^*$ fits as the magnetic dual of the dilaton while the two terms on the middle line are higher duals of the D0 and D6-branes [50].

In the usual gravity language, the D0-brane sources the Kaluza-Klein vector, while the D6-brane is its magnetic charge. The fact that the magnetic charge comes directly from this reduction makes sense of the idea that the starting setup includes a kind of magnetic dual of gravity.

B.4 Some decompositions of $E_8(8) \times \mathbb{R}^+$

Here we will briefly look at some of the other decompositions of $E_8(8) \times \mathbb{R}^+$, and their relevance to supergravity. We gave the $GL(8, \mathbb{R})$ decomposition and one of the $Spin(8, 8)$ decompositions in section 3. This subgroup resulted in a generalised geometry. The decompositions listed here do not lead to geometries (with the exception of B.4.5), but are helpful examples for understanding how the Dynkin diagrams relate to the fields and charges. One sequence of embeddings we examine is

$$E_8(8) \times \mathbb{R}^+ \rightarrow O(8, 8) \times \mathbb{R}^+ \rightarrow O(7, 7) \times O(1, 1) \times \mathbb{R}^+$$

(B.13)

where the $O(7, 7)$ subgroup corresponds to the T-duality group of the type II theories. We emphasise that the middle group here is a different $O(8, 8)$ subgroup to the one considered in section 3.

Another decomposition one can consider is that of $E_8(8) \times \mathbb{R}^+ \rightarrow E_{7(7)} \times SL(2, \mathbb{R}) \times \mathbb{R}^+$. The two orientations of the gravity line in this subalgebra will be seen to correspond to a subsector of the type IIB theory including the dual graviton and a new generalised geometry for a subsector of type IIA.

B.4.1 $O(8, 8) \times \mathbb{R}^+$ extension of T duality in 7 dimensions

The (continuous) T-duality group in seven-dimensions is $O(7, 7)$. This group is contained in an $O(8, 8)$ subgroup of $E_8(8)$, so to begin with, we examine the decomposition $O(8, 8) \times \mathbb{R}^+ \rightarrow O(7, 7) \times O(1, 1) \times \mathbb{R}^+$

$$ad(O(8, 8) \times \mathbb{R}^+)_0 \rightarrow ad(O(7, 7))_{(0,0)} \oplus \mathbf{7}_{(+1,0)} \oplus \mathbf{7}_{(-1,0)} \oplus \mathbf{1}_{(0,0)}$$

(B.14)
where in the pairs of weights on the right hand side, the first refers to the $O(1, 1)$ factor, while the second refers to the original $\mathbb{R}^+$ factor in $O(8, 8) \times \mathbb{R}^+$.

We now embed $GL(7, \mathbb{R})$ into $O(7, 7) \times O(1, 1) \times \mathbb{R}^+$ so that $1_{(+1,0)} \simeq \Lambda^7 T$ and $1_{(0,+1)} \simeq \Lambda^7 T^*$, and the embedding into the $O(7, 7)$ factor is such that the vector decomposes as $T \oplus T^*$ as in [2]. We then have the $GL(7, \mathbb{R})$ decompositions:

\[
7_{(+1,+1)} \simeq (T \oplus T^*) \otimes \Lambda^7 T \otimes \Lambda^7 T^* \\
\simeq T \oplus T^* \\
7_{(-1,+1)} \simeq (T \oplus T^*) \otimes (\Lambda^7 T^*)^2 \\
\simeq ((\Lambda^7 T^*)^2 \otimes T^*) \oplus (\Lambda^7 T^* \otimes \Lambda^6 T^*) \\
91_{(0,+1)} \simeq ((T \otimes T^*) \oplus \Lambda^2 T \oplus \Lambda^2 T^*) \otimes \Lambda^7 T^* \\
\simeq \Lambda^5 T^* \oplus (T^* \otimes \Lambda^6 T^*) \oplus (\Lambda^7 T^* \otimes \Lambda^2 T^*) \\
1_{(0,+1)} \simeq \Lambda^7 T^*
\]

The generalised tangent space for this group would be the adjoint of $O(8, 8)$ with unit $\mathbb{R}^+$ weight.

\[
E \simeq 120_{+1} \simeq T \oplus T^* \oplus \Lambda^5 T^* \oplus (T^* \otimes \Lambda^6 T^*) \oplus \Lambda^7 T^* \\
\oplus (\Lambda^7 T^* \otimes \Lambda^6 T^*) \oplus (\Lambda^7 T^* \otimes \Lambda^2 T^*) \oplus ((\Lambda^7 T^*)^2 \otimes T^*) \\
\]

It is clear that the first line of this corresponds to the NS-NS sector complete with magnetic duals. The terms added to the usual tangent space correspond to the string, the NS5-brane, the dual graviton and the magnetic dual of the dilaton. The three terms on the second line are higher duals for the string, NS5-brane and graviton respectively.

Looking at the decomposition

\[
E \otimes E \simeq [1, 0, \ldots, 0; 0, 0]_{+1} \otimes [1, 0, \ldots, 0; 0, 0]_{+1} \\
= 1_{+2} \oplus [0, 0, 1, 0, 0, 0; 0, 0]_{+2} \oplus [1, 0, \ldots, 0; 0, 0]_{+2} \oplus [0, \ldots, 0; 0, 2]_{+2} \oplus [0, 1, 0, \ldots, 0; 0, 1]_{+2} \oplus [2, 0, \ldots, 0; 0, 0]_{+2} \\
\]

one can read off that

\[
N \simeq 1_{+2} \oplus [0, \ldots, 0; 0, 2]_{+2} \oplus [0, 0, 1, 0, 0, 0; 0, 0]_{+2} \\
\]

The algebras for this magnetic completion of the NS-NS sector also form a series, whose diagrams we draw as

\[
\begin{array}{c}
\begin{array}{cccc}
& (d + 1) & & d \\
E & \circlearrowright & \circlearrowright & \circlearrowright \\
1 & & & (d - 1)
\end{array}
\end{array}
\]
Due to the appearance of the potential for the dual graviton, these do not straightforwardly define generalised geometries in dimensions $d \geq 7$. The case $d = 6$ has group $SO(6,6) \times SL(2,\mathbb{R}) \times \mathbb{R}^+ \subset E_{7(7)} \times \mathbb{R}^+$ corresponding to a slight enhancement of ordinary generalised geometry by an $SL(2,\mathbb{R})$ factor. These algebras have been identified before [52] in the very similar context of type I supergravity, and a similar algebra was considered in [36] in the context of the bosonic string.

B.4.2 $O(8,8) \times \mathbb{R}^+$ decomposition of $E_{8(8)} \times \mathbb{R}^+$

Embedding the above in $E_{8(8)} \times \mathbb{R}^+$, gives us the $GL(7,\mathbb{R})$ decomposition of $E_{8(8)} \times \mathbb{R}^+$ relevant to the type II theories

$$E \simeq \text{ad}(O(8,8))_{+1} \oplus \mathbf{128}^\pm_{+1}$$

where we take $+$ for type IIB and $-$ for type IIA. The decomposition of the first term is the common NS-NS sector as above. The decomposition of the second term is

$$\mathbf{128}^+_1 \simeq \mathbb{R} \oplus \Lambda^2 T^* \oplus \Lambda^4 T^* \oplus \Lambda^6 T^*$$

$$\oplus \left[ \Lambda^7 T^* \otimes \left( \Lambda^7 T^* \oplus \Lambda^5 T^* \oplus \Lambda^3 T^* \oplus T^* \right) \right]$$

for the type IIA case and

$$\mathbf{128}^-_{+1} \simeq T^* \oplus \Lambda^3 T^* \oplus \Lambda^5 T^* \oplus \Lambda^7 T^*$$

$$\oplus \left[ \Lambda^7 T^* \otimes \left( \Lambda^6 T^* \oplus \Lambda^4 T^* \oplus \Lambda^2 T^* \oplus \mathbb{R} \right) \right]$$

for type IIB. These clearly correspond to the D-branes of these theories, and some kind of higher duals [50].

As noted in [51], the diagrams corresponding to the type IIA and IIB decompositions should be drawn as

for type IIA, the “folding up” of the right-most node corresponding to KK reduction (as in B.1), and

for type IIB.
B.4.3 $E_{7(7)} \times SL(2, \mathbb{R})$ in type IIB

Here we briefly look at the subsector corresponding to the $E_{7(7)} \times SL(2, \mathbb{R}) \times \mathbb{R}^+$ subgroup in the type IIB decomposition. One has

$$E \simeq (133,1)_{+1} \oplus (56,2)_{+1} + (1,3)_{+1}$$  \hspace{1cm} (B.22)

where

$$(133,1)_{+1} \simeq T \oplus \Lambda^3 T^* \oplus (T^* \otimes \Lambda^6 T^*) \oplus (\Lambda^7 T^* \otimes \Lambda^4 T^*) \oplus ((\Lambda^7 T^*)^2 \otimes T^*)$$

$$(56,2)_{+1} \simeq 2 \times \left[ T^* \oplus \Lambda^5 T^* \oplus (\Lambda^7 T^* \otimes \Lambda^2 T^*) \oplus (\Lambda^7 T^* \otimes \Lambda^6 T^*) \right]$$  \hspace{1cm} (B.23)

$$(1,3)_{+1} \simeq 3 \times (\Lambda^7 T^*)$$

This corresponds to a different embedding of $GL(7, \mathbb{R})$ in $E_{7(7)}$ to the one considered in [4]. Clearly, this is a different reorganisation of the type IIB decomposition of the previous section, the $SL(2, \mathbb{R})$ factor corresponding to the S-duality symmetry. For this construction, we would draw the diagram

```
       o
  o---o---o---o---o
    E
```

the nodes added above the fourth node and zeroth node from the right indicating that the algebra is generated by $\Lambda^4 T \oplus \Lambda^4 T^*$ and $\Lambda^0 T \oplus \Lambda^0 T^*$. The interpretation of the very extended $E_7$ algebra as a subsector of type IIB has appeared before in [34].

In this case one has

$$E \otimes E \simeq 1_{+2} \oplus [1,0,\ldots,0,0;0]_{+2} \oplus [0,0,0,0,1,0;0]_{+2}$$

$$\oplus [0,1,0,\ldots,0;0]_{+2} \oplus [2,0,\ldots,0;0]_{+2}$$  \hspace{1cm} (B.24)

so that

$$N \simeq 1_{+2} \oplus [0,0,0,0,1,0;0]_{+2}$$  \hspace{1cm} (B.25)

Removing one node from the left of the diagram here, we recover the $d = 6$ case of section 2, enhanced by an additional $SL(2, \mathbb{R})$ factor, which also includes the axion-dilaton system in the geometry.

B.4.4 $E_{8(8)}$ adjoint in type IIB

The adjoint is the $248_0$ representation. We can get the $GL(7, \mathbb{R})$ decomposition of this from the above simply by multiplying all terms by $\Lambda^7 T$ to remove the $\mathbb{R}^+$ weight. This is typical of restrictions to $d = D - 3$ dimensions, where the presence of the dual
graviton typically makes the representation for $E$ a weighted version of the adjoint, and one can notice that the operation exchanges fields with their duals. This observation aids us in identifying the field relevant to each term. For brevity, we give only the type IIB decomposition

\[
\begin{pmatrix}
\text{Graviton: } T \\
\text{Dual Gravtion: } T^* \otimes \Lambda^6 T^* \\
\text{2nd Dual: } \left( (\Lambda^7 T^*)^2 \otimes T^* \right)
\end{pmatrix}
\xrightarrow{\otimes \Lambda^7 T} \left( (T \otimes T^*) \oplus (T \otimes \Lambda^7 T) \oplus (T^* \otimes \Lambda^7 T^*) \right)
\]

\[
\begin{pmatrix}
\text{F1: } T^* \\
\text{Dual F1: } \Lambda^7 T^* \otimes \Lambda^6 T^*
\end{pmatrix}
\longrightarrow (\Lambda^6 T \oplus \Lambda^6 T^*)
\]

\[
\begin{pmatrix}
\text{NS5: } \Lambda^5 T^* \\
\text{Dual NS5: } \Lambda^7 T^* \otimes \Lambda^2 T^*
\end{pmatrix}
\longrightarrow (\Lambda^2 T \oplus \Lambda^2 T^*)
\]

\[
\begin{pmatrix}
\text{D1: } T^* \\
\text{Dual D1: } \Lambda^7 T^* \otimes \Lambda^6 T^*
\end{pmatrix}
\longrightarrow (\Lambda^6 T \oplus \Lambda^6 T^*)
\]

\[
\begin{pmatrix}
\text{D3: } \Lambda^3 T^* \\
\text{Dual D3: } \Lambda^7 T^* \otimes \Lambda^4 T^*
\end{pmatrix}
\longrightarrow (\Lambda^4 T \oplus \Lambda^4 T^*)
\]

\[
\begin{pmatrix}
\text{D5: } \Lambda^5 T^* \\
\text{Dual D5: } \Lambda^7 T^* \otimes \Lambda^2 T^*
\end{pmatrix}
\longrightarrow (\Lambda^2 T \oplus \Lambda^2 T^*)
\]

\[
\begin{pmatrix}
\text{D7: } \Lambda^7 T^* \\
\text{Dual dilaton: } \Lambda^7 T^*
\end{pmatrix}
\longrightarrow (\mathbb{R} \oplus \mathbb{R})
\]

The first part of the adjoint is the subsector of B.2. The remaining parts exchange the fields and their duals, for example the parts of $E$ relevant to the NS5-brane becoming the parts of the adjoint relevant to the string and vice-versa. The remaining NS-NS seven-form in $E$ is mapped to the algebra generator $\mathbb{R}$ which corresponds to the dilaton, hence we identify this seven-form as the dual dilaton (as in B.3).

**B.4.5 $E_{7(7)} \times SL(2, \mathbb{R})$ in type IIA**

Here we present a sketch of the subsector corresponding to the $E_{7(7)} \times SL(2, \mathbb{R}) \times \mathbb{R}^+$ subgroup in the type IIA decomposition. This subgroup actually leads to a generalised geometry with diagram

```
    O
   / \   /
  /   \ /   /
 O---O---O---O
```

B.26
This is the “gravity-line-reversal” of the type IIB geometry of B.4.3.

We choose the embedding of \( GL(7, \mathbb{R}) \) in \( E_{7(7)} \times SL(2, \mathbb{R}) \times \mathbb{R}^+ \) such that

\[
\begin{align*}
\text{ad}(E_{7(7)}) &\simeq (T \otimes T^*) \oplus (\Lambda^2 T \oplus \Lambda^3 T^*) \oplus (\Lambda^6 T \oplus \Lambda^6 T^*) \\
\text{ad}(SL(2, \mathbb{R})) &\simeq \mathbb{R} \oplus \Lambda^7 T \oplus \Lambda^7 T^* \\
1_{+1} &\simeq (\Lambda^7 T^*)
\end{align*}
\]

(B.27)

The generalised tangent space corresponds to the \((56, 2)_{+1}\) representation which then decomposes as

\[
E \simeq T \oplus \Lambda^2 T^* \oplus \Lambda^5 T^* \oplus \Lambda^6 T^* \\
\oplus \left[ \Lambda^7 T^* \otimes (\Lambda^5 T^* \oplus \Lambda^2 T^* \oplus T^*) \right] \\
\oplus \left( (\Lambda^7 T^*)^2 \otimes T^* \right)
\]

(B.28)

The first line includes the charges for the D2, NS5 and D6-branes, while the second line contains their dual charges. The last line is the higher dual of the graviton. The adjoint includes potentials only for the pure-form charges, so that there are no problems with the generalised geometric construction. It is an extension of the \( E_{7(7)} \times \mathbb{R}^+ \) geometry of \([4, 5]\) by the \( SL(2, \mathbb{R}) \) factor.

By the method of A.2, one finds that

\[
N \simeq 1_{+2} \oplus (133, 2)_{+2} \oplus (1539, 1)_{+2}
\]

(B.29)

while the only non-vanishing part of antisymmetric partial derivatives lives in the \((1539, 3)_{+2}\) representation.

### B.5 Six-dimensional \( N = (1, 0) \) supergravity

Here we briefly mention how one can see similar structures in six-dimensional theories with 8 supercharges. The corresponding infinite dimensional algebras and relation to the supergravity has previously appeared in \([53]\).

For pure six-dimensional minimal supergravity restricted to three dimensions, consider \( SO(4, 3) \times \mathbb{R}^+ \) with the diagram\(^6\)

\[
\begin{array}{c}
\text{3} \\
\text{1} \\
\text{E} \\
\text{2}
\end{array}
\]

\(^6\)Note that this diagram is a collapsed version of the diagrams in section B.4.1.
This leads to the $GL(3, \mathbb{R})$ decompositions

$$
E \simeq T \oplus T^* \oplus (T^* \otimes \Lambda^2 T^*) \oplus (\Lambda^3 T^* \otimes \Lambda^2 T^*) \oplus ((\Lambda^3 T^*)^2 \otimes T^*)
$$

$$
ad \simeq \mathbb{R} \oplus (T \otimes T^*) \oplus \Lambda^2 T \oplus \Lambda^2 T^* \oplus (T \otimes \Lambda^3 T) \oplus (T^* \otimes \Lambda^3 T^*)
$$

(B.30)

decompositions showing that we have a two-form gauge field and the dual graviton. Due to the latter, the usual generalised geometry construction fails. The representation for $N$ comes out to be

$$
N \simeq 1_{+2} \oplus [0, 2; 0]_{+2} \oplus [0, 0; 2]_{+2}
$$

(B.31)

One can see the exact same behaviour if one considers adding vector and tensor multiplets in six dimensions. The relevant group cosets are well-known (see [60] for a review of their geometry). For example, for the $SO(5, 4) \times \mathbb{R}^+$ case we draw the diagram as

![Diagram](image)

and find the $GL(3, \mathbb{R})$ decompositions

$$
E \simeq T \oplus T^* \oplus (T^* \otimes \Lambda^2 T^*) \oplus (\Lambda^3 T^* \otimes \Lambda^2 T^*) \oplus ((\Lambda^3 T^*)^2 \otimes T^*)
$$

$$
\oplus \left[ T^* \oplus \Lambda^3 T^* \oplus (\Lambda^3 T^* \otimes \Lambda^2 T^*) \right]
$$

$$
\oplus \left[ \mathbb{R} \oplus \Lambda^2 T^* \oplus (\Lambda^2 T^* \otimes T^*) \oplus (\Lambda^3 T^*)^2 \right]
$$

$$
ad \simeq \mathbb{R} \oplus (T \otimes T^*) \oplus \Lambda^2 T \oplus \Lambda^2 T^* \oplus (T \otimes \Lambda^3 T) \oplus (T^* \otimes \Lambda^3 T^*)
$$

$$
\oplus \left[ \mathbb{R} \oplus \Lambda^2 T \oplus \Lambda^2 T^* \right]
$$

$$
\oplus \left[ T \oplus T^* \oplus \Lambda^3 T \oplus \Lambda^3 T^* \right]
$$

(B.32)

which one can easily identify as adding a vector multiplet and a tensor multiplet (both with magnetic duals included) to the pure supergravity above. One can find similar decompositions for the theories related to the other very special quaternionic cosets.

The above algebras are relevant to restrictions of six-dimensional theories to $d = 3$ dimensions. One could instead examine the restriction to $d = 2$. In this case, there is no dual graviton and the construction of [3–5] is expected to go through. However, this is of limited interest for studying backgrounds, as there can be no $H(3)$ flux in two dimensions.
