Abstract

This study involves automatically identifying the sociolinguistic characteristics of fictional characters in plays by analyzing their written “speech”. We discuss three binary classification problems: predicting the characters’ gender (male vs. female), age (young vs. old), and socioeconomic standing (upper-middle class vs. lower class). The text corpus used is an annotated collection of August Strindberg and Henrik Ibsen plays, translated into English, which are in the public domain. These playwrights were chosen for their known attention to relevant socioeconomic issues in their work. Linguistic and textual cues are extracted from the characters’ lines (turns) for modeling purposes. We report on the dataset as well as the performance and important features when predicting each of the sociolinguistic characteristics, comparing intra- and inter-author testing.

1 Introduction

A speech community has sociolinguistic properties. Social variables influencing verbal interaction include, for example, geographical background, gender, age, ethnicity, and class. Writers and playwrights, in turn, use their knowledge of social verbal markers to generate credible and compelling characters. The focus of this study is the creation of an annotated dataset and computational model for predicting the social-biographical aspects of fictional characters based on features of their written “speech” in dramatic plays. The plays used here are authored by August Strindberg and Henrik Ibsen, two Scandinavian playwrights known for creating characters and stories that acted as social commentary and were controversial when they were first written. These authors are also recognized for their contributions in shaping modern drama. Their attention to social issues makes these plays and characters highly relevant in constructing such a model to shed light on how these authors’ translated texts portray social variables. Interlocutors’ social attributes (such as their gender, age, social class, and ethnicity) are known to correlate with language behavior, and they tap into dimensions of language behavior that are of central interest to the humanities. For instance, anecdotal evidence suggests that large-scale corpus analysis can show how society collectively assigns certain roles to male versus female referents in text (cf. Lindquist, 2009).

Studying these authors and texts from the point of view of corpus-oriented computational sociolinguistics can also help us examine the authors’ differences in production, descriptively. This is useful as a complementary approach to the more traditional close reading methodology common in literary research, through which their texts are usually approached. On a broader scale, the study can contribute valuable insights to a theory of linguistic text criticism. These authors are part of a global literary canon, and their plays are arguably more often performed in translation than in their Scandinavian originals. Accordingly, we focus on analyzing texts translated into English.

We focus on sociolinguistic characteristics that are assigned to each character and that can be described as translating into three binary classification problems: predicting the characters’ gender (male vs. female), age (young vs. old), and socioeconomic standing or class (upper-middle class vs. lower class). The text corpus is annotated by assigning each of the characters that match specified criteria a value in each of the characteristics. We do this at the character level, joining all dialogic lines of a character into one instance. The work was accomplished through the use of computational tools...
for natural language processing, including Python (http://www.python.org/), the Natural Language Toolkit (http://www.nltk.org/) for part of the pre-processing, and the scikit-learn machine learning library for the computational modeling. Translated texts that reside in the public domain were collected from the Gutenberg Archive (http://www.gutenberg.org/wiki/Main_Page/).

2 Previous Work

A pilot study by Hota et al. (2006) on automatic gender identification in Shakespeare’s texts, as well as a few primarily gender-oriented studies surveyed in Garera and Yarowsky (2009), have set the stage for further inquiry. The latter study expanded on previous work by exploring three attributes: gender, age, and native/non-native speakers. There have been previous avenues of research into categorizing speakers based on different individual sociolinguistic factors. However, not many studies have attempted this categorization with fictional characters. Literary texts are complex, reflecting authors’ decision-making and creative processes. From the perspective of digital humanities, such a focus complements computational sociolinguistic modeling of contemporary user-generated text types (such as emails, or blogs (Rosenthal and McKeown, 2011)). As Lindquist (2009) points out, social data for interlocutors is less often attached to openly available linguistic corpora, and interest is strong in developing corpus methods to help explore social language behavior (see Lindquist (2009) and Baker (2010)).

Previous investigation into social dimensions of language has established strong links between language and social attributes of speech communities (for an overview, see Mesthrie et al. (2009)). However, such inquiry has generally had a firm foundation in field-based research and has usually focused on one or just a few linguistic variables (such as how the pronunciation of certain sounds aligns with social stratification (Labov, 1972)). Moreover, previous scholarship has chiefly focused on the spoken rather than the written mode. Garera and Yarowsky (2009) and Boulis and Ostendorf (2005) take into account the interlocutors’ speech for analysis. In contrast, we experiment with the challenge of using only sociolinguistically relevant knowledge coded in the text of characters’ lines. Thus, our approach is more similar to Hota et al.’s (2006) work on Shakespeare.

The characters’ lines do not include the metadata needed for considering spoken features, since usually these are added at the discretion of the performer. This may make our problem more challenging, since some of these indicators may be reliable for identifying gender, such as backchannel responses and affirmations from females, and assertively “holding the floor” with filled pauses from males (Boulis and Ostendorf, 2005). Moreover, there are prosodic features that clearly differ between males and females due to physical characteristics (e.g. F0, predominant for pitch perception). We do not take advantage of acoustic/prosodic cues in this work. Our text is also artificial discourse, as opposed to natural speech; therefore these characters’ lines may rather express how writers choose to convey sociolinguistic attributes of their characters.

In terms of features, we have explored observations from previous studies. For instance, common lexical items have been shown successful, with males tending to use more obscenities, especially when talking to other males (Boulis and Ostendorf, 2005), and females tending to use more third-person pronouns. Phrases also tended to be more useful than unigrams, though whether the commonly-used words tend to be content-bearing remains a question according to Boulis and Ostendorf (2005). Tackling another form of text, Kao and Jurafsky (2012) examined the statistical properties of 20th century acknowledged versus amateur poets in terms of style and content substance, finding, for example, that lexical affluence and properties coherent with imagism, as an aesthetic theorized ideal, distinguished contemporary professionals’ poetics, while sound phenomena played a lesser role, and amateurs preferred the use of more explicit negative vocabulary than professionals. In our study, we focus on data collection, corpus analysis, and exploratory experimentation with classification algorithms.

3 Data

The texts used were freely available transcriptions from the Gutenberg Archive. English translations of public-domain plays by August Strindberg and Henrik Ibsen were collected from the archive, from various translators and years of release. As noted above, these plays are often performed in English, and we assume that the translations will convey relevant linguistic cues, as influenced by
Table 1: Distribution of plays, characters, and lines between Strindberg and Ibsen in the dataset.

| Attribute     | Annotation | Strindberg | Ibsen | Total |
|---------------|------------|------------|-------|-------|
| Gender        | Male / Female | 42 / 23   | 61 / 32 | 103 / 55 |
| Age           | Old / Young  | 46 / 19   | 61 / 32 | 107 / 51 |
| Class         | Upper / Lower | 57 / 8    | 83 / 10 | 140 / 19 |

Table 2: Example annotations from Miss Julia.

| Character   | Gender | Age | Class |
|-------------|--------|-----|-------|
| Christine   | Female | Young | Upper |
| Jean        | Male   | Young | Lower |
| Miss Julia  | Female | Young | Lower |

Table 3: Character attribute distributions for gender, age, and class for each author.

In Scandinavia (Swedish native speaker) based on her knowledge of Scandinavian naming conventions. Example character annotations for Strindberg’s well-known naturalistic play Miss Julia (or Miss Julie) are shown in Table 2. As seen in Table 3, the imbalance of class labels presents the greatest problem for our model. Baselines of 88% and 89% upper class for Strindberg and Ibsen, respectively, indicate that there may be less information to be extracted for class.

4 Models

Here we describe the design and performance of computational models for predicting a character’s gender, age, and class for Strindberg and Ibsen, yielding six models in total. Logistic regression, implemented in Python with the scikit-learn machine learning library (Pedregosa et al., 2011), is used for all classification models.

4.1 Feature Extraction

Many features were examined, some inspired by previous analyses in the literature, such as type-token ratio, subordinate clauses, and wh-questions, as well as some exploratory features, such as honorific terms of address. A full list of the features examined is shown in Table 4. All features were automatically extracted using Python. We use honorifics here to mean common formal terms of address during the time period (sir, madam, lord, Mr., Mrs., etc.). It seems intuitive that such terms may be used differently based on class or possibly age (e.g. lower class using more higher terms of address when speaking to their superiors). We use family words to mean anything that indicates a familial relationship (father, daughter, nephew; etc.). The use of such words may be affected by gender roles (Hota et al., 2006). Part-of-speech tagging was accomplished using the Natural Language Toolkit (NLTK) (Bird et al., 2009).
4.2 Cross-Author Validation

We compared translations of Strindberg and Ibsen’s use of language to convey sociolinguistic attributes. This was done for each of the three attributes of interest (gender, age, and class) by training one model for each author, then using it to classify the other author’s characters. We accomplish this by defining a cross-author validation procedure, a variation of the standard $k$-fold cross-validation procedure in which the trained model in each fold is used to predict both its own test set and the test set of the other author. This procedure is explained visually in Figure 1. The procedure is especially interesting as these two authors were contemporaries and dealt with topics of social commentary in their works, although from their own perspectives.

The results of cross-author validation are shown in Table 5 as a matrix where the row is the author used for training, the column is the author used for testing, and the value inside a cell is the average accuracy over all iterations of cross-author validation. Majority class baselines are also shown. As expected, the models for each author’s texts were better at predicting themselves than the other author, with a couple of exceptions. For age, the Strindberg-trained model was still able to improve on Ibsen’s baseline, but not vice versa. One possible explanation could be that common features between their depictions of age might be more useful for one author than the other. Another interesting exception is in the class models for both authors, which performed slightly above high baselines for the opposite authors as well as their own. While class improvements are recognizably marginal (and not claimed to be significant), these results might indicate that the two authors’ translated texts are using similar characteristics to convey social class of their characters. It is important to note that the baselines for class were extremely high, making prediction of this attribute more difficult. At least in the intra-author testing, the gender and age models were generally able to improve accuracy over their respective baselines more so than the class models, with age being the best overall.

4.3 Comparison of Useful Features

Since the experimentation used a linear model (logistic regression), we can inspect the coefficients/weights of a trained classifier to determine which features contributed particularly to the classification. The absolute value of a coefficient indicates how influential its feature is, and the sign $(+/-)$ of the coefficient indicates which class the feature is associated with. During cross-author
validation, if the trained classifier for a given fold performed above the baseline of its own test set, then we record its three most heavily weighted features. At the end, we have a tally of which features most often appeared in the top three features for such better-performing classifiers. We can use this to compare which features were more consistently involved for each author and attribute pair, as shown in Table 6.

Some of the useful features are more intuitive than others. For example, as mentioned in an earlier section, it seems reasonable that family words may relate to depictions of gender roles of the time period in which the plays were written, with women being expected to take on social roles more confined to the home. This appears to be true for Ibsen, but not for Strindberg. We also see family words suggesting young characters for both authors’ texts. It seems intuitive that authors may have chosen to depict children as spending more time around family members, including using family terminology as terms of address. The use of honorifics is also as predicted earlier in the paper: lower class characters use more higher terms of address, presumably when interacting with their superiors. Another interesting result is the frequency of third-person pronouns being the most useful predictor of gender, indicating female characters for both authors. Possibly, women may have spoken more about other people than men did in these texts.

Some other results are not as easy to explain. For example, the use of the prepositions for and with was consistently the most useful predictor of lower class characters (which could explain why the models performed comparably on opposite authors in Table 5). An interesting result was the more frequent use of singular, present tense, non-third person verbs among young characters in the Ibsen texts. This suggests that young characters used more verbs centered around I and you in the present tense. One possible explanation is that children were depicted as being more involved in their own personal world, speaking less about people they were not directly interacting with in a given moment.

5 Conclusion

We have presented a dataset of translated plays by August Strindberg and Henrik Ibsen, along with computational models for predicting the sociolinguistic attributes of gender, age, and social class of characters using the aggregation of their textual lines-to-be-spoken. We compared the performance and important features of the models in both intra- and inter-author testing using a cross-author validation procedure, finding that models generally performed above challenging baselines for their own authors, but less so for the other, as one would expect. The exception was the social class variable, which was consistently slightly above baseline regardless of the author used for testing. While this could indicate that the translated Strindberg and Ibsen texts conveyed social class using similar linguistic cues, this remains a topic for future exploration, given the class imbalance for that attribute. We also examine some indicative features for each attribute and author pair, identifying similarities and differences be-

| Strindberg | Ibsen |
|------------|-------|
| Gender     | Pronouns 3rd | Female | Pronouns 3rd | Female |
|            | Honorifics   | Female | Family words | Female |
|            | Determiners  | Male   | Modals        | Male   |
| Age        | Nouns singular | Old   | Family words | Young  |
|            | Family words | Young  | Verbs sing. pres. non-3rd | Young  |
|            | Modals       | Young  | Prepositions  | Old    |
| Class      | For/with     | Lower  | For/with      | Lower  |
|            | Verbs past part. | Upper | Honorifics    | Lower  |
|            | Honorifics   | Lower  | Nouns singular | Lower  |

Table 6: Most useful features for gender, age, and class for each author, determined by examining the coefficients of classifiers that performed above baseline during cross-author testing. The pairs in the table consist of a linguistic feature and the label indicated by more frequent use of that feature (e.g. for Strindberg, third-person pronoun usage contributed to predicting gender, with greater usage indicating a female character). Features marked in bold are shared between authors for a given attribute.
tween the depictions in each set of texts. This analysis supported the trends seen in the cross-author testing.

Future work would include exploring other authors and literary genres, or extending the scope to non-literary domains. When expanding this initial work to larger datasets, there is an opportunity to better understand the intricacies of performance through other metrics (e.g., precision, recall). There is certainly much opportunity to expand sociolinguistic features on fictional texts and to explore other potentially simpler or more advanced modeling frameworks. Alternatives for assigning annotation of sociolinguistic variables, such as socioeconomic standing, also deserve further attention. Additionally, it would be interesting to verify the preservation of linguistic/sociolinguistic cues in translation by repeating this work using different translations of the same texts.
