ABSTRACT

Solvent evaporation technique is employed to cast films of cured Epoxy resin in Diethylenetriamine. Diethylenetriamine is an organic solvent. Polymer and curing agent concentration is varied in wt/wt ratio. The FTIR studies are employed as a tool to identify the functional groups and the importance of curing agent. Samples are subjected to mechanical studies and mechanical parameters -toughness, flexural and tensile strengths are established. Dielectric studies are performed at different concentrations of curing agent.

Keywords: FTIR, Tensile Strength, Flexural Strength, Toughness, Curing Agent, Epoxy Resin, Diethylenetriamine

INTRODUCTION

The synthesis of materials as films is an indispensable step in many applications. Films play a crucial role in the enhancement and study of materials with new and peculiar properties. The titled compound (EP) is the significant material with exemplary properties, which is extensively utilized in semiconductor accessories manufacturing unit, adhesives, aerospace and other fields. Epoxy resins, are referred to as polyepoxides- comes under the category of reactive prepolymers. Epoxy monomer’s vital feature is the oxirane ring functional group, it is a three-member ring made of oxygen and two carbon atoms. The doping of other materials to enhance the strength of the epoxy resin has been a vital research field.

EXPERIMENTAL

Epoxy Resin

The titled compound is semi-polymeric or polymeric materials or an oligomer and seldom exists in pure form. Unprocessed epoxy resins have less chemical, mechanical, heat and moisture resistance properties. These properties are enhanced by promoting the reaction of epoxy resin with proper curing agents to create a network of three-dimensional cross-linked thermoset structures. This process is referred to as curing or gelation process. Curing process of epoxy resins is an exothermic reaction and releases thermal radiation to cause thermal degradation if not controlled. To enhance the performance of epoxy resins, even diffusion after mixing is vital. The polymer was purchased from M/s ROTO POLYMERS Chennai.

Diethylenetriamine

Resins linked with amine hardeners have better mechanical and thermal properties. Amine compounds are categorized as primary, secondary, and tertiary amines, in which one, two, and three hydrogen molecules of ammonia (NH₃) have been replaced by hydrocarbon, respectively. Amines are once again categorized into monoamine, diamine, tri-amine, or polyamine based on the number of amines present in one
molecule and according to the types of hydrocarbons substituted, as aliphatic, alicyclic and aromatic amines. Curing of resins with the help of the aliphatic amines is strong, and is exemplary in bonding nature.\textsuperscript{12} Diethylentetramine (abbreviated DETA) falls under the category of an organic compound with the formula HN(CH\textsubscript{2}CH\textsubscript{2}NH\textsubscript{2})\textsubscript{2}. DETA is a hygroscopic liquid. This colorless liquid is soluble in water, polar organic solvents, but insoluble in hydrocarbons, with an ammonia-like odor. DETA is utilized in the chemical, pharmaceutical industry and employed as a solvent for plastics, dyes and in the chemical manufacturing unit, fabric softeners and fuel additives. DETA is used as a solvent for resins, colors, acid gases, and sulfur and as a hardener in epoxy resins.\textsuperscript{13} Boiling point is 206°C and its refractive index is 1.484. Diethylentetramine was purchased from M/s SISCO RESEARCH LABORATORIES Pvt. Ltd. Navi Mumbai, India. The curing process of Epoxy resin in Diethylentetramine is carried out. Films are cast by the solvent evaporation method. A homogeneous mixture of epoxy resin with different concentration of curing agent is produced, utilizing magnetic stirrer Remi model. The films are produced by employing the simple technique of concentration variation of both the resin and curing agent. The concentrations of films are 2\%, 6\%, 16\% (weight by weight) of DETA are prepared.

**Characteristic Studies**

The IR spectrum of a substance is the emplacement of the absorption bands of peculiar functional groups.\textsuperscript{14} The vibrational frequencies are a kind of fingerprint of the compounds. This property is used for study of organic, inorganic, polymer, smart and biological compounds. The band intensities are directly related to the concentration of the compound and hence quantitative and qualitative evaluations are possible. Spectral studies are carried out using The Perkin Elmer Spectrum Two FT-IR instrument. The utility of IR spectroscopy is possible using a Fourier transform technique. The entire region of 4000 – 450 cm\textsuperscript{-1} is focused by this instrument. Mid-infrared spectroscopy has been collectively utilized for the study of organic compounds, a lot of sustainable information and spectra libraries can be easily traced out. FTIR spectroscopy provides both the qualitative and quantitative data about the material, but its usage to epoxy systems is quite restrained due to the position and concentration of the oxirane ring absorptions.\textsuperscript{9} The mechanical tests are conducted by using ASTM D-638-00 using an Instron testing machine Model5567. Mechanical tests are carried out in the laboratory at Central Leather Research Institute, Chennai. The load is increased at a uniform rate and the specimen elongates and finally ruptures. Dielectric studies are carried out at Loyola college, Chennai. Dielectric studies are carried out at a temperature of 80° C.

**RESULTS AND DISCUSSION**

**Spectral Analysis**

FTIR studies are carried on pure epoxy resin without curing agent, DETA and epoxy resin with varying concentration of DETA. FTIR spectrum of pure epoxy resin without curing agent is projected in Fig.-1. FTIR spectrum of DETA is shown in Fig.-2. FTIR spectra of Epoxy resin with varying concentration of DETA are shown Fig.-3. Vibrational band assignments are made. Films undergo CO\textsubscript{2} deformation at 555 cm\textsuperscript{-1}. Similarly, epoxy resin films with varying concentration of curing agent 2\%, 6\%, 16\% undergo stretching vibration of C-O-C oxirane ring at 825 cm\textsuperscript{-1} - 826 cm\textsuperscript{-1}. Similarly, an epoxy resin film undergoes stretching of C-O at 1181 cm\textsuperscript{-1}. Similarly, films of epoxy resin with varying concentration of curing agent 2\%, 6\%, 16\% undergoes O-H deformation at 1232 cm\textsuperscript{-1} – 1243 cm\textsuperscript{-1}. Similarly, films of epoxy resin with varying concentration of curing agent 2\%, 6\%, 16\% undergoes stretching of N-H at 3287 - 3289 cm\textsuperscript{-1}. The study of relative relation of area of functional group with a concentration of curing agent is carried out. From the study, it is confirmed as an area of the functional group of FTIR spectra increases, the percentage of concentration of curing agent decreases, shown in Table-1 and Fig.-4.
Mechanical studies are carried out on epoxy resin films with the changing concentrations of curing agent 2%, 6%, 16%. The variation of stroke with stress is studied. It is concluded that as % of the concentration of curing agent increases the tensile strength, flexural strength, toughness also gets enhanced. Table 2 and
figure 5 highlights the fact - % of the concentration of curing agent increases, all the mechanical parameters such as tensile strength, flexural strength and toughness also increases. Mechanical studies are used as the tool to establish the role of curing agent is to increase the hardness of films.

**Dielectric Studies**

Dielectric studies are carried out on epoxy resin films with varying concentration of 6%, 16% of curing agent at temperatures 80°C, from Fig.-6 and Fig.-7 it is confirmed as dielectric constant increases frequency decreases for all concentrations.

**CONCLUSION**

Both spectral analysis and mechanical studies confirm the role of curing agent. Epoxy resin film with 16% of curing agent responded well for spectroscopic and mechanical studies. A dielectric study confirms as frequency increases dielectric constant decreases.
Table-2: Variation of Tensile Strength, Flexural Strength and Toughness with Varying Concentration of Curing Agent

| S. No. | The concentration of Curing agent in % | Tensile strength N | Flexural Strength N | Toughness N |
|--------|--------------------------------------|--------------------|-------------------|-------------|
| 1      | 2                                    | 4.19               | 0.34              | 0.35        |
| 2      | 6                                    | 5.00               | 2.22              | 2.33        |
| 3      | 16                                   | 8.00               | 4.02              | 4.22        |
