Breaking Diversity Restriction: Distributed Optimal Control of Stand-alone DC Microgrids

Zhaojian Wang, Feng Liu, Ying Chen, Steven Low, Fellow, IEEE, and Shengwei Mei, Fellow, IEEE

Abstract—Stand-alone direct current (DC) microgrids may belong to different owners and adopt various control strategies. This brings great challenge to its optimal operation due to the difficulty of implementing a unified control. This paper addresses the distributed optimal control of DC microgrids, which intends to break the restriction of diversity to some extent. Firstly, we formulate the optimal power flow (OPF) problem of stand-alone DC microgrids as an exact second order cone program (SOCP) and prove the uniqueness of the optimal solution. Then a dynamic solving algorithm based on primal-dual decomposition method is proposed, the convergence of which is proved theoretically as well as the optimality of its equilibrium point. It should be stressed that the algorithm can provide control commands for the three types of microgrids: (i) power control, (ii) voltage control and (iii) droop control. This implies that each microgrid does not suffer from voltage deviation in the steady state. Moreover, the control commands for power controlled and voltage controlled microgrids satisfy generation limits and voltage limits in both transient process and steady state. Finally, a six-microgrid DC system based on the microgrid benchmark is adopted to validate the effectiveness and plug-n-play property of our designs.

Index Terms—Distributed control, DC microgrid, optimal power flow, diversity restriction, transient constraint.

I. INTRODUCTION

MICROGRIDS are clusters of distributed generators (DGs), energy storage systems (ESSs) and loads, which are generally categorized into two types: alternating current (AC) and direct current (DC) microgrids [1], [2]. In the past decade, research has been concentrated on enhancing the performance of AC microgrids. However, some generations and loads are inherently DC, such as photo-voltaic (PV), battery, computer and electrical vehicle (EV) [3]–[5]. DC microgrids more naturally integrate them and can eliminate unnecessary conversion processes, which improves system efficiency and reliability. In addition, DC systems do not face problems such as reactive power compensation, frequency stability and synchronization [6], which makes it more and more popular in power system. In DC microgrids, hierarchical control is often utilized [6], [7], i.e., primary control, secondary control and tertiary control, which can be implemented in either a centralized manner or a distributed manner. In the centralized manner, a control center is needed to accumulate information from microgrids, compute command and send it back to them. With the increasing number of microgrids as well as uncertainties of renewable generations and load demands, centralized control faces a great challenge, i.e., it is less and less applicable due to problems, e.g., single point failures, heavy communication burden of control center and lack of ability to respond rapidly enough [8]. These problems highlight the need for a distributed control strategy that will require no control center and less communication. This paper addresses this need.

In the hierarchical control architecture, the primary control is almost decentralized. The most popular control manner is the droop control [6], [9], where load sharing is mainly determined by the droop coefficient. As pointed out in [10], [11], droop control cannot achieve proper load sharing sometimes, especially in systems with unequal resistances and different modes. Many improvements are investigated [10]–[14]. Taking into consideration the effect of different line impedances, [10] proposes a decentralized control strategy to achieve perfect power sharing. In [11], a mode-adaptive decentralized control strategy is proposed for the power management in DC microgrid, which enlarges the control freedom compared with the conventional droop control. In [14], a decentralized method is proposed to adjust the droop coefficient by the state-of-charge of storage, which can achieve equal load sharing. However, similar to the AC power system, primary control in DC system suffers from voltage deviation in the steady state.

To eliminate the voltage deviation, distributed secondary control is developed. The most widely used method is consensus based control [15], where there is usually a global control variable, e.g., global voltage deviation, while each agent only has its local estimation. In the DC system, each agent may represent a DG or a microgrid. By exchanging information with neighbors, the value of the variable will be identical for all agents finally [7], [16]–[18]. In [7], each microgrid uses dynamic consensus protocol to estimate the global averaged voltage with the local and neighboring estimation. Then, the estimated voltage is compared with the reference value and fed to a PI controller to eliminate the voltage deviation. This method is further improved in [17] by adding a current consensus regulator, where the control goal is to achieve globally identical current ratio compared with the rated current of each microgrid. By doing so, the equal load sharing can be obtained. The discrete consensus method is used in [18] to restore average voltage with accurate load sharing. The consensus based secondary control can realize equality among
agents, however, the results may not be optimal.

Tertiary control is to achieve the optimal operation by controlling the power flow among microgrids or among DGs within a microgrid [19–21]. Conventionally, tertiary control provides reference operation point for the system. Its time scale is much slower than real time control. However, values of renewable generations and loads may change rapidly due to uncertainties, which makes reference point obtained by tertiary control sub-optimal in the new situation. This requires us to combine real-time coordination and steady-state optimization together, i.e., the optimization solution should be sent to the system in real time. Similar works are given in both AC system [22–24] and DC system [25–27].

The critical thought in [25] is that the incremental generation cost of each microgrid is identical in the steady state. In [25], economic dispatch problem is formulated and the incremental generation cost is regarded as consensus variable. Using the consensus method, the incremental generation cost will be identical in the steady state, and optimality is achieved. Similar method is also used in [27], where the sub-gradient is added to the consensus approach in order to accelerate the convergence. These works are very inspiring in combination of optimal operation and real time control, but they still have some restrictions. For example, the original control strategy of a microgrid has to be revised to the proposed method, which is hard to apply as microgrids may belong to different owners and adopt various control strategies. These problems highlight the need for a distributed control strategy that is less influenced by the diversity.

In this paper, we investigate the distributed optimal power flow control among stand-alone DC microgrids, which is less influenced by their original control strategies. We construct an optimal power flow (OPF) model for stand-alone microgrids with an exact SOCP relaxation and further prove the uniqueness of its optimal solution. By using the primal-dual decomposition method, a distributed dynamic algorithm is proposed, which provides control commands for different control strategies such as power control, voltage control and droop control. This implies that we do not change the original control schemes of microgrids, which breaks the restriction of microgrid diversity. In addition, constraints of generation capacity limits and voltage limits are enforced even in the transient process of control commands, which implies power commands are always feasible and voltage commands are safe for converters. In this regards, it increases the security of DC system. Furthermore, we also prove the convergence of the optimization solution.

The contributions of this paper have following aspects:

- The OPF model of stand-alone DC power system is formulated, and the uniqueness of its optimal solution is proved.
- A fully distributed algorithm is proposed to achieve the optimal solution of the OPF problem, where only communications with neighbors are needed with minimal communication burden.
- The proposed method does not change the original control strategy of each DG, which adapts to three most common control modes: power control, voltage control and droop control, breaking restriction of microgrid diversity.
- The control commands for power controlled and voltage controlled microgrids satisfy generation limits and voltage limits in both transient process and steady state.

The rest of the paper is organized as follows. In Section II, network model of DC microgrids is introduced. In Section III, OPF model for stand-alone DC microgrids is formulated. In Section IV, the dynamic algorithm is proposed, the optimality and convergence of the algorithm are proved theoretically. The implementation approach is designed in Section V. Case studies are given in Section VI. Finally, Section VII concludes the paper.

II. NETWORK MODEL

A stand-alone DC system is composed of a cluster of microgrids connected by lines. Each microgrid is treated as a bus with generation and load. Then the whole system is modeled as a connected graph $G := (\mathcal{N}, \mathcal{E})$, where $\mathcal{N} = \{1, 2, ... n\}$ is the set of microgrids and $\mathcal{E} \subseteq \mathcal{N} \times \mathcal{N}$ is the set of lines. If two microgrids $i$ and $k$ are connected by a tie line directly, we denote $(i, k) \in \mathcal{E}$, and abbreviated by $i \sim k$. The resistance of line $(i, k)$ is $r_{ik}$. The power flow from microgrid $i$ to microgrid $k$ is $P_{ik}$, and the current from microgrid $i$ to $k$ is $I_{ik}$. Let $m := |\mathcal{E}|$ be the number of lines.

For each microgrid $i \in \mathcal{N}$, let $p^g_i(t)$ denote the generation at time $t$ and $p^d_i(t)$ denotes its constant load demand. Denote the voltage at bus $i$ as $V_i$. DGs in the DC microgrids may have different control strategies, such as power control, voltage control and droop control. Power control and voltage control only require their reference values, which are not introduced here in detail. Droop control takes the form:

$$v_i - v_i^* = -k_i(p^g_i - \hat{p}_i).$$

where $v_i = V_i^2$, $k_i > 0$ is the droop coefficient, $v_i^*$ is the voltage square reference, and $k_i, v_i^*$ are constants. $\hat{p}_i$ is the power when $v_i = v_i^*$, which is a variable in the rest of the paper.

Denote the current in line $(i, k)$ from $i$ to $k$ as $I_{ik}$, which is defined

$$I_{ik} = (V_i - V_k)/r_{ik}.$$  

Then the power $P_{ik}$ from $i$ to $k$ is

$$P_{ik} = V_iI_{ik} = V_i(V_i - V_k)/r_{ik}$$

Consequently, the power balance in one node is

$$p_i^g - p_i^d = V_i \sum_{k: k \in N_i}(V_i - V_k)/r_{ik}$$

where $N_i$ is the set of microgrids connected with microgrid $i$ directly. Our goal is to provide control commands for microgrids adopting different control strategies, which must satisfy the operational constraints:

$$0 \leq p_i^g \leq p_i^d$$

$$V_i \leq V_i \leq \overline{V}_i$$

where $p_i^d$ is the upper limit of generation in DG $i$, $V_i$, $\overline{V}_i$ are lower and upper limits of voltage. For power controlled DG,
is a hard limit, which must be satisfied even during the transient process. Otherwise it is non-executable. For voltage controlled DG, (5b) is not a hard limit, but it also should be satisfied during the transient. This is because overlimit voltage is not secure for the converter nor the operator.

III. OPTIMAL POWER FLOW PROBLEM

A. OPF Model

Existing OPF models are mainly for grid-connected DC system [23]. However, DC microgrids also operate in isolated mode in many situations such as in remote areas or islands. In terms of this, we formulate the ordinary OPF in the stand-alone DC power system.

OPT: \[
\begin{align*}
\min_{p^g, v, W} & \quad f = \sum_{i \in \mathcal{N}} f_i(p^q_i) \\
\text{s.t.} & \quad (5a) \\
& \quad V_i^2 - v_i^2 \leq V_i^2, \quad i \in \mathcal{N} \quad (6b) \\
& \quad p^q_i - p^q_i = \sum_{k \sim i} (v_i - W_{ik})/r_{ik}, \quad i \in \mathcal{N} \quad (6c) \\
& \quad W_{ik} = 0, \quad i \sim k \quad (6d) \\
& \quad W_{ik} = W_{ki}, \quad i \sim k \quad (6e) \\
& \quad R_{ik} \geq 0, \quad i \sim k \quad (6f) \\
& \quad \text{rank}(R_{ik}) = 1, \quad i \sim k \quad (6g)
\end{align*}
\]

where \( R_{ik} = \begin{bmatrix} v_i & W_{ik} \\ W_{ki} & v_i \end{bmatrix} \). If rank\( (R_{ik}) = 1 \) always holds, \( W_{ik} \) can be divided into \( W_{ik} = V_{ik}v_k \). The cost \((6a)\) is a function of generation in each node, which should satisfy

A1: \( f_i(p^q_i) \) is strictly increasing when \( p^q_i \geq -p^d_i \) for \( i \in \mathcal{N} \), second order continuous differentiable and strongly convex \( f_i'(p^q_i) \) is strictly increasing.

Constraint \((6b)\) is derived from \((5b)\), and \((6c)\) is from \((4a)\). Constraint \((6d)\) implies matrix \( R_{ik} \) is positive semi-definite, and \((6g)\) guarantees the rank of \( R_{ik} \) be 1. The difference between \((6)\) and OPF in \([23]\) is that there is no substation node with fixed voltage in \((6)\). \((6g)\) is not convex due to constraint \((6g)\). Remove \((6g)\), and we get the SOC relaxation of \((6)\).

SOCP: \[
\begin{align*}
\min_{p^g, v, W} & \quad \sum_{i \in \mathcal{N}} f_i(p^q_i) \\
\text{s.t.} & \quad (5a), (6b) - (6f)
\end{align*}
\]

It has been proved in \([29]\) that the relaxation is exact provided that: 1) \( V_1 = V_2 = \cdots = V_n = V_k \); 2) \( p^q_i > 0 \); 3) \( \sum_{i \in \mathcal{N}} (p^q_i - p^d_i) > 0 \); 4) \( f_i'(p^q_i) \) is strictly increasing when \( p^q_i \geq p^d_i \) for \( i \in \mathcal{N} \). In this paper, conditions 1), 2), 3) are satisfied. With assumption A1, 4) is also satisfied.

To improve the numerical stability of the SOC, we have the following stable SOC problem.

SSOCP: \[
\begin{align*}
\min_{p^g, P, I, v} & \quad \sum_{i \in \mathcal{N}} f_i(p^q_i) \\
\text{s.t.} & \quad (4b), (5a) \\
& \quad P_{ik} + P_{ki} = r_{ik}l_{ik}, \quad i \sim k \\
& \quad v_i - v_k = r_{ik}(P_{ik} - P_{ki}), \quad i \sim k \quad (7c) \\
& \quad l_{ik} \geq P^2_{ik}/v_i, \quad i \sim k \quad (7d) \\
& \quad V_i^2 \leq v_i^2 \leq V_i^2, \quad i \in \mathcal{N} \quad (7e)
\end{align*}
\]

where \( l_{ik} = |f_i|^2 \) are squared line currents, and \( l_{ik} = l_{ki} \).

Constraint \((7d)\) is the SOC relaxed form. The detailed explanation of \((7d)\) is found in \([28]\), which is omitted here.

According to Theorem 5 in \([28]\), SOC and SSOCP are equivalent, i.e., there exists a one-to-one map between the feasible set of SOC and the feasible set of SSOCP, which is

\[
\begin{align*}
P_{ik} &= (v_i - W_{ik})/R_{ik}, \quad i \sim k \\
l_{ik} &= (v_i - W_{ik} - W_{ki} + v_k)/R_{ik}, \quad i \sim k.
\end{align*}
\]

In some microgrids, droop control is utilized. However, the solution of \((7)\) cannot guarantee \( v_i \) and \( P^2_i \) satisfy \((1)\), which implies that the optimal solution may not be achieved in reality. In this regard, we add droop control to the constraints, then the problem becomes

DSOCP: \[
\begin{align*}
\min_{p^g, P, I, v, \hat{p}} & \quad \sum_{i \in \mathcal{N}} f_i(p^q_i) \\
\text{s.t.} & \quad (1), (4b), (5a), (7c) - (7e)
\end{align*}
\]

In DSOCP, the droop coefficient is a constant, while \( \hat{p} \) is an optimization variable, making DSOCP a convex problem.

To help design the algorithm, an equivalent optimization problem is formulated.

ESOCP: \[
\begin{align*}
\min_{p^g, P, I, v, \hat{p}} & \quad \sum_{i \in \mathcal{N}} f_i(p^q_i) + \sum_{i \in \mathcal{N}} \frac{1}{2} y_i^2 + \sum_{i \in \mathcal{N}} \frac{1}{2} z_i^2 \\
\text{s.t.} & \quad (1), (4b), (5a), (7c) - (7e)
\end{align*}
\]

where \( y_i = v_i + k_2 p^2_i - v_i^* - k_2 \hat{p}_i \), \( z_i = p^q_i - P^2_i - \sum_{k \sim i} P_{ik} \).

Since for any feasible solution of ESOCP we all have \( y_i = z_i = 0 \), ESOCP is equivalent to DSOCP. \( y_i \) and \( z_i \) are only put here to accelerate the convergence of the algorithm \([30]\).

B. Uniqueness of Optimal Solution

Before introducing the results, we give an assumption.

A2: The OPF \((4)\) is feasible.

Then, we have the following theorem.

Theorem 1. Suppose A1 and A2 hold. The optimal solution of SSOCP is unique.

The proof of Theorem 1 is given in Appendix A.

Theorem 2. Denote the optimal solution of SSOCP as \( x^* = (p^{2*}_1, p^{2*}_2, t^{2*}_1, v^{1*}) \) and the optimal solution of DSOCP as \( x^{2*} = (p^{2*}_1, p^{2*}_2, t^{2*}_2, v^{2*}) \). Then,

1) there exists an unique \( \hat{p}^{2*} \) making \( x^* \) the optimal solution of DSOCP;

2) the optimal solution of DSOCP is unique;

3) \( (p^{2*}_1, p^{2*}_2, t^{2*}_2, v^{2*}) = (p^{1*}, P^{1*}, t^{1*}, v^{1*}) \).

The proof of Theorem 2 is given in Appendix A.

Suppose the optimal solution of DSOCP is \( x^{2*} = (p^{2*}_1, p^{2*}_2, t^{2*}_2, v^{2*}, \hat{p}^{2*}_i) \) with the droop coefficient \( k_{i1} \). From the proof of 1) in Theorem 2, if \( k_{i1} \) changes to \( k_{i2} \), there exists an unique \( \hat{p}^{2*} \) making \( (p^{2*}_1, P^{2*}_2, t^{2*}_2, v^{2*}, \hat{p}^{2*}_i) \) be the optimal solution of DSOCP. This implies that droop coefficient does not influence the optimal solution of SSOCP.
**Lemma 3.** Optimization problem ESOCP and DSOC have identical feasible solutions.

It is easy to prove Lemma 3 as $y_i = 0$ and $z_i = 0$ for any feasible solution.

**Remark 1.** From Theorem 2, it is shown that the unique optimal solution still exists even if droop control is considered, and we can obtain the optimal $p^*_d$ in droop control. Moreover, for these microgrids that do not adopt droop control, ESOCP can provide the optimal output power and voltage references. In addition, for different droop coefficient $k_i$, $(p^2_i, P^*_2, I^2_2, v^2_2)$ in the optimal solution does not change. Thus, for microgrids that do not adopt droop control, we can just assign an imaginary droop control to them when formulating ESOCP, i.e., assuming all the microgrids adopts droop control when building ESOCP. This does not influence the optimal solution of these microgrids adopting power control and voltage control. In this regard, our method adapts to three different control strategies.

**IV. CONTROL SCHEME DESIGN**

**A. Distributed Algorithm**

Based on the primal-dual algorithm, we propose the following distributed algorithm to solve the ESOCP, which is

$$
\dot{p}_i^0 = [p_i^0 - (G_i(p_i^0) - \mu_i + k_i \epsilon_i + z_i + k_i y_i)]p_i^0 - p_i^0 \quad (9a)
$$

$$
\dot{v}_i = \left[ v_i - \left( y_i + \sum_{k \in N_i} \gamma_{ik} + \epsilon_i - \sum_{k \in N_i} \rho_{ik} \frac{p_i^2}{v_i^2} \right) \right] \frac{\nabla v^2}{v^2} - v_i \quad (9b)
$$

$$
\dot{\hat{p}}_{ik} = -(\mu_i + \lambda_{ik} - \gamma_{ik} r_{ik} + 2 \rho_{ik} P_{ik}/v_i - z_i) \quad (9c)
$$

$$
\dot{l}_{ik} = -(-\lambda_{ik} r_{ik} - \rho_{ik} - \rho_{ik}) \quad (9d)
$$

$$
\dot{\hat{y}}_i = k_i \epsilon_i + k_i y_i \quad (9e)
$$

$$
\dot{\hat{p}}_i = -(\hat{p}_i^2 - \hat{p}_i^d - \sum_{k \in N_i} P_{ik}) \quad (9f)
$$

$$
\dot{\epsilon}_i = v_i - k_i \hat{p}_i^2 - v_i^* - k_i \hat{p}_i \quad (9g)
$$

$$
\dot{\lambda}_{ik} = P_{ik} + P_{ki} - r_{ik} l_{ik} \quad (9h)
$$

$$
\dot{\gamma}_{ik} = v_i - v_k - r_{ik} (P_{ik} - P_{ki}) \quad (9i)
$$

$$
\dot{\hat{p}}_i = [P_i^2/v_i - l_{ik}]^+ \quad (9j)
$$

where $G_i(p_i^0) := \frac{\partial}{\partial p_i} f_i(p_i^0)$. For any $x_i, a_i, b_i$ with $a_i \leq b_i$, $[x_i]_{a_i}^b := \min \{ b_i, \max \{ a_i, x_i \} \}$. Operator $\lceil a \rceil$ is

$$
[x_i]_{a_i}^b = \begin{cases} x_i, & \text{if } a_i > 0 \text{ or } x_i > 0; \\ 0, & \text{otherwise.} \end{cases}
$$

The algorithm (9) is fully distributed where each MG updates its internal states $p_i^0, P_{ik}, l_{ik}, \hat{v}_i, \hat{p}_i, \mu_i, \epsilon_i, \lambda_{ik}, \gamma_{ik}, \rho_{ik}$ relying only on local information and neighboring information. The neighboring information only appear in variables $P_{ki}, v_k, \rho_{ki}, k \in N_i$.

Next, we will investigate the boundedness of $(p_i^0(t), v_i(t))$. Firstly we introduce the assumption

**A3:** The initial states of the dynamic system (9) are finite, and $(p_i^0(0), v_i(0))$ satisfy constraint (5).

Define the set

$$
X := \{(p_i^0, v_i)|0 \leq p_i^0 \leq \overline{p_i^0}, v_i \leq \overline{v_i}\},
$$

then we will prove the boundedness property of $(p_i^0(t), v_i(t))$.

**Lemma 4.** Suppose assumption A3 holds. Then constraint (5) is satisfied for all $t \geq 0$, i.e., $(p_i^0(t), v_i(t)) \in X$ for all $t \geq 0$ where $X$ is defined in (10).

**Proof of Lemma 4** Note that (9a) is an inertia link with input

$$
u_i^0 = [p_i^0 - (G_i(p_i^0) - \mu_i + k_i \epsilon_i + z_i + k_i y_i)]p_i^0
$$

According to the feature of inertia link, $p_i^0(t) \in X$ for all $t \geq 0$ holds as long as $u_i^0(t) \in X$ for all $t \geq 0$. Thus, we know $p_i^0(t) \in X$ for all $t \geq 0$ always holds. Similarly, $v_i(t) \in X$ for all $t \geq 0$ always holds. This completes the proof. \qed

Lemma 4 implies that inequality constraints are enforced even in the transient for $p_i^0$ and $v_i$.

**B. Optimality of Equilibrium Point**

In this subsection, we will prove that the equilibrium points of (9) are primal-dual optimal for ESOCP and its dual, and vice versa. Firstly, the definition of equilibrium points of (9) and the optimal solution of ESOCP are given in Definition 1 and Definition 2 respectively.

Given $x_p := (p^*, P^*, l^*, v^*, \hat{p}^*, \mu^*, \epsilon^*, \lambda^*, \gamma^*, \rho^*)$ is an equilibrium point of (9) if the right-hand side of (9) vanishes at $(x_p^*, x_d^*)$.

**Definition 1.** A point $(x_p^*, x_d^*) := (p^*, P^*, l^*, v^*, \hat{p}^*, \mu^*, \epsilon^*, \lambda^*, \gamma^*, \rho^*)$ is an equilibrium point of (9) if the right-hand side of (9) vanishes at $(x_p^*, x_d^*)$.

**Definition 2.** A point $(x_p^*, x_d^*)$ is primal-dual optimal if $x_p^*$ is optimal for its dual problem and $x_d^*$ is optimal for its dual problem.

To prove the optimality of $(x_p^*, x_d^*)$, we make the following assumption:

**A4:** Slater’s condition for ESOCP holds.

We first illustrate that the saturation of controller does not influence the optimal solution of ESOCP, which is introduced in Lemma 5.

**Lemma 5.** Suppose A1, A2 and A4 hold. If $(x_p^*, x_d^*)$ is primal-dual optimal, we have

$$
p_i^0 = [p_i^0 - (G_i(p_i^0) - \mu_i + k_i \epsilon_i + z_i + k_i y_i)]p_i^0
$$

$$
\dot{v}_i = \left[ v_i - \left( y_i + \sum_{k \in N_i} \gamma_{ik} + \epsilon_i - \sum_{k \in N_i} \rho_{ik} \frac{P_i^2}{(v_i^2)} \right) \right] \frac{\nabla v^2}{v^2} - v_i
$$

The proof of Lemma 5 is given in Appendix B. Based on Lemma 5, we have the following Theorem.

**Theorem 6.** Suppose A1, A2, A3 and A4 hold. A point $(x_p^*, x_d^*)$ is primal-dual optimal if and only if it is an equilibrium of the dynamic system (9).

The proof of Theorem 6 is given in Appendix B.
C. Convergence Analysis

In this subsection, we will justify the convergence of the algorithm (9) by projection gradient theory combined with invariance principle for switched system.

Define the sets \( \sigma_\rho \):
\[
\sigma_\rho := \{(i,k) \in \mathcal{E} \mid \rho_{ik} = 0, \ P_{ik}^2/v_i - l_{ik} < 0\}
\]
Then (9) is equivalent to
\[
\dot{\rho}_{ik} = \begin{cases} 
\rho_{ik}(P_{ik}^2/v_i - l_{ik}), & \text{if } (i,k) \notin \sigma_\rho; \\
0, & \text{if } (i,k) \in \sigma_\rho.
\end{cases}
\]
(11)

From (11), it is easy to know \( \dot{\rho}_{ik}(t) \geq 0, \forall t \).

Denote \( x := (p_{ik}^2, v_i, P_{ik}, l_{ik}, \bar{p}_i, \epsilon_i, \lambda_i, \gamma_i, \rho_{ik}) \) and define \( F(w) \) in a fixed \( \sigma_\rho \).

\[
F(x) = \begin{bmatrix}
G_i(p_{ik}^2) + k_i\epsilon_i - \mu_i + z_i + k_i y_i \\
y_i + \sum_{k:ik \in \mathcal{N}_i} \gamma_{ik} + \epsilon_i - \varphi_i^+ + \varphi_i^- - \sum_{k:ik \in \mathcal{N}_i} \rho_{ik} p_{ik}^2/v_i^2 \\
\mu_i + \lambda_i - \gamma_{ik} r_{ik} + 2 \rho_{ik} p_{ik}^2/v_i - z_i \\
\lambda_{ik} r_{ik} - \rho_{ik} - \rho_{ki} \\
-k_i \epsilon_i - k_i y_i \\
p_{ik}^2 - p_i^2 - \sum_{k:ik \in \mathcal{N}_i} P_{ik} \\
-v_i + k_i p_{ik}^2 - v_i - k_i \bar{p}_i \\
(P_{ik} + P_{ki} - r_{ik} l_{ik}) \\
-v_i - v_k + r_{ik} (P_{ik} - P_{ki}) \\
- [P_{ik}/v_i - l_{ik}]_{\rho_{ik}}
\end{bmatrix}
\]
(12)

\( F(x) \) is continuously differentiable in a fixed \( \sigma_\rho \).

We further define the set
\[
S := X \times \mathbb{R}^{7m+3n}
\]
where \( X \) is given in (10). For any \( x \), the projection \( x - F(x) \) onto \( S \) is
\[
H(x) := \text{Proj}_S (x - F(x)) := \arg \min_{y \in S} \|y - (x - F(x))\|_2
\]
where \( \| \cdot \|_2 \) is the Euclidean norm. Then, the algorithm (9) can be rewritten as
\[
\dot{x}(t) = H(x(t)) - x(t)
\]
(13)

A point \( x^* \in S \) is an equilibrium of (13) if and only if it is a fixed point of the projection:
\[
H(x^*) = x^*
\]

Let \( E := \{x \in S \mid H(x(t)) - x(t) = 0\} \) be the set of equilibrium points.

**Theorem 7.** Suppose A1, A2, A3 and A4 hold. Then every trajectory \( x(t) \) of (13) starting from a finite initial state asymptotically converges to some equilibrium \( x^* \in E \) as \( t \to +\infty \) that is optimal for problem ESOCP.

The proof of Theorem 7 is provided in Appendix C.

V. IMPLEMENTATION

Each microgrid may adopt different control strategies: voltage control, power control or droop control. Different strategies require different control commands, which are \( p_{ik}^0, v_i, \bar{p}_i \), respectively. Since we combine optimization with real time control, values of \( p_{ik}^0, v_i, \bar{p}_i \) in the transient process are also sent to the corresponding DGs as the control commands. To distinguish with state variables \( p_{ik}^0, v_i, \bar{p}_i \), control commands sent to DGs are denoted as \( p_{ik}^{ref}, v_i^{ref} \) and \( \bar{p}_i^{ref} \) respectively. For voltage and power control, the algorithm (9) can provide \( p_{ik}^{ref} \) and \( v_i^{ref} \) that are all feasible even in the transient process. For the droop control microgrids, we can supply \( \bar{p}_i^{ref} \), which ensures the system operate in the optimal status. The control diagrams for three types of microgrid are shown in Fig[1].

In Fig[1] the left part is the proposed algorithm, the inputs of which are local information \( p_{ik}^0, P_{ik}, l_{ik}, v_i, \bar{p}_i, \mu_i, \epsilon_i, \lambda_i, \gamma_{ik}, \rho_{ik} \) and neighbor information \( P_{ki}, v_k, \rho_{ki}, k \in \mathcal{N}_i \). The outputs are \( p_{ik}^{ref}, v_i^{ref} \) and \( \bar{p}_i^{ref} \). The right part is the diagrams of three control strategies: power control, voltage control and droop control. For power controlled DG, it has two control
loops, power loop and current loop, where \(I_{ref}\) is the current reference for the current control loop and \(I_i\) is the measured current. For voltage controlled DG, it also has two control loops, power loop and current loop, where \(v_i\) is the measured voltage. For droop controlled DG, it has three control loops, droop control loop, power loop and current loop, where both voltage and current need to be measured.

From Fig 1, we can see that our method adapts to three commonly used control strategies, which in some sense implies it breaks restriction of various control strategies in microgrids in achieving optimal operation point.

**Remark 2.** In fact, for microgrid \(i\), neighbor information \(P_{ki}\) and \(v_k\) can be estimated locally by the following equations

\[
P_{ki} = P_{ik} - r_{ik}I_{ik}^2
\]

\[
v_k = (\sqrt{v_i} - r_{ik}I_{ik})^2
\]

where line current \(I_{ik}\) from microgrid \(i\) to \(k\) can be measured locally. Then, only \(r_{ki}, k \in N_i\) need to be exchanged between neighbors, which implies that the communication burden is minimized.

In the real system, some microgrid may switch off or switch on unexpectedly. The system should also operate optimally in this situation. This requires the controller has the capability of plug-n-play, which will be shown in the simulation.

**VI. CASE STUDIES**

**A. Test System**

To verify the effectiveness of the proposed approach, a multi-microgrid DC system is utilized, the topology of which is based on the low voltage microgrid benchmark in [31]. The system includes two feeders with six dispatchable DGs, which are divided into six microgrids based on corresponding DGs. The Breaker 1 is open, and the system operates in an isolated way. The simulation is performed in PSCAD joint with Matlab. More specifically, the DC microgrids are modeled in PSCAD, whereas algorithm (9) is computed in Matlab. They are combined by a user-defined interface. The control commands obtained in Matlab are sent to corresponding microgrids in PSCAD through the interface. Conversely, MATLAB can also collect data from PSCAD. In this regards, the PSCAD represents the physical system, while MATLAB represents the cyber system. Communication exists in cyber system to obtain the neighborhood information. The joint simulation flowchart is illustrated in Fig 3.

The objective function is set as \(f_i(p_i^g) = \frac{a_i}{2}(p_i^g)^2 + b_i p_i^d\), which represents the generation cost of the whole system as the generation cost also takes the quadratic form [27], [32]. If \(b_i > 0\), it satisfies A1. Some parameters for these microgrids are provided in Table I. The simulation case is that load demands in each microgrid is (41, 40, 42, 39, 42, 40)kW at first, then they will increase to (51, 50, 52, 49, 52, 50)kW at time 1s. All the three regular control strategies are utilized, i.e, DG1 and DG6 adopt droop control, DG2 and DG5 use power control while DG3 and DG4 adopt voltage control.

**B. Accuracy Analysis**

In this subsection, we also use CVX tool in Matlab to solve ESOPC, results of which after load increases are utilized as basic values to validate the accuracy of the proposed approach. Results of these two methods are compared in Table II.

In Table II \(p_i^d\) and \(\hat{p}_i^d\) are \(d\) and \(\hat{d}\) of all DGs obtained by the proposed approach, while \(p_i^e\) and \(\hat{p}_i^e\) are values obtained using the CVX tool. \(e\) is the errors of \(p_i^d\) and \(\hat{p}_i^d\) with regards to \(p^e\) and \(\hat{p}_e\). From results in Table II it can be seen that the absolute errors between \(p_i^d\) and \(\hat{p}_i^d\) in each MGs are smaller than 0.07%. In addition, the absolute errors between \(\hat{p}_i^d\) and

| 5    | 49.9761             | 50.0053             | -0.0584    | 48.8660        | 48.3499        | 0.4470     |
| 6    | 42.1217             | 42.1495             | -0.0660    | 39.2465        | 39.2176        | 0.0737     |

\( \tilde{p}_{d}^{c} \) are smaller than 0.6%. Both validate the accuracy of the proposed approach.

C. Dynamic Process

In this subsection, we analyze the impacts of generation limits on the dynamic property. To do this, we compare dynamic responses of the inverter outputs in microgrids 2 and 5 by two scenarios: with and without saturation. The trajectories in two cases are given in Fig.4. In both cases, the steady state generations are achieved. However, with the saturated controller, the generations of DG2 and DG5 remain within the limits in both transient and steady state. On the contrary, generator of DG2 and DG5 violate their upper limits in the transient, which is practically infeasible.

Similarly, we also compare the voltage dynamics of DG3 and DG4 in two scenarios: with and without saturation. The trajectories in two cases are given in Fig.5. In both cases, the same steady state voltages are achieved. However, with the saturated controller, the voltages of DG3 and DG4 remain within the limits in both transient and steady state. On the contrary, voltages of DG3 and DG4 violate their upper limits in the transient process if saturation is not considered. As we know, the high voltage is both harmful to the power electronic equipments and system operators. In this sense, our method can increase system security.

We reset \( p_{d}^{c} = (60, 55, 60, 65, 48, 50) \) kW at \( t = 9s \), where the power limits of DG2 and DG5 are reduced to 55kW and 48kW respectively. This implies that they can be strictly reached in the steady state. This scenario often happens in microgrids since generation limits of renewable resources such as wind turbines and PVs can change rapidly due to uncertainties. The generations of all DGs with different capacity constraints are given in Fig.6.

We have checked that generations in Fig.6 are identical with results obtained by CVX. In Fig.6, it is shown that generations of DG2 and DG5 reduce rapidly to the capacity limits in the new situation. Other DGs will change their generations to balance the power mismatch in the whole system. This implies our methodology can adapt to disturbances of renewable generations.

D. Plug-n-play Analysis

In this case, microgrid 6 is switched off at 1s, then it is switched on at 9s. When microgrid 6 is switched off, it has to supply the load demand itself while microgirds 1 to 5 remain connected. Voltage and generation dynamics in the whole process are illustrated in Fig.7.

It is shown that output of DG6 increases to 50kW to supply the load in microgrid 6 after being switched off. At the same time, the voltage of DG6 reduces to 400V. The result is identical with that obtained by CVX. In addition, after microgrid 6 is switched on once again, the generations and voltages of all DGs recover to the original values. Moreover, by comparing the voltages in the transient process, it is shown that only the two DGs connected directly with the breaking
point are influenced greatly, while other DGs like DG1-DG4 have very moderate transient process. This validates that our controller can realize plug-n-play.

VII. CONCLUSION

This paper addresses the distributed optimal control of stand-alone DC microgrids, where each microgrid may adopt one of the three different control strategies, such as power control, voltage control and droop control. The controller can provide commands for all these strategies, which implies it breaks restriction of various control strategies to achieve optimal operation point. A six-microgrid system based on the microgrid benchmark is utilized to demonstrate the efficacy of our designs. The error of results between proposed method and CVX tool is smaller than 0.6%, which validates the accuracy of the proposed approach. Moreover, the commands for power controlled and voltage controlled microgrids satisfy generation limits and voltage limits in both transient process and steady state. This increases the security of DC system. In addition, our controller can adapt to the uncertainties of renewable generations. Finally, the proposed approach can realize the plug-n-play.

The tie-line limit is not considered in this work since the convex relaxation may be not exact if it is included. In the normal operation, tie line limit in microgrids is often satisfied by planning stage. However, it is also very important when large disturbance happens. In the future research, we will investigate approaches to addressing this problem.

From the proof of Theorem 3 in [28], we know (1). Since two problems have the same objective function and map (8), solution of SSOCP is also unique. This completes the proof.

With assumption A1, A2 and A4, the strong duality holds.

Proof. If A2 holds, problem (7) is also feasible due to the one-to-one map [8]. It suffices to prove the uniqueness of the optimal solution of SOCP. Let \( x^{1*} = (p^{2*1*}, v^{1*}, W^{1*}) \) and \( x^{2*} = (p^{2*2*}, v^{2*}, W^{2*}) \) be two optimal solutions of SOCP, then we have

\[
\sum_{i \in N} f_i(p_i^{1*} - p_i^d) = \sum_{i \in N} f_i(p_i^{2*} - p_i^d) \quad (A.1)
\]

From the proof of Theorem 3 in [28], we know

\[
\begin{align*}
\frac{v_i^{1*}}{v_i^{2*}} &= \frac{v_i^k}{v_i^{k+1}} = \eta_i, \quad i \sim k \\
W_{ik}^{1*} &= \sqrt{v_i^{1*} v_k^{1*}} = \eta_i W_{ik}^{2*}
\end{align*}
\]

From (4a), we have

\[
p_i^{1*} - p_i^d = \sum_{k: k \sim i} (v_i^{1*} - W_{ik}^{1*})/r_{ik} = \sum_{k: k \sim i} (v_i^{2*} - \eta_i W_{ik}^{2*})/r_{ik} = \eta_i (p_i^{2*} - p_i^d)
\]

Since \( f_i(p_i^d - p_i^d) \) is strictly increasing, we must have \( \eta_i = 1 \), otherwise it contradicts (A.1). We have \( x^{1*} = x^{2*} \), implying the uniqueness of SOCP solution. According to the one-to-one map [8], solution of SSOCP is also unique. This completes the proof.

B. Proof of Theorem 2

Proof. \( \Rightarrow 1 \) Suppose \( x^{1*} = (p^{21*}, P^{11*}, l^{1*}, v^{1*}) \) is the optimal solution of (7), there exists an unique \( \hat{p} \) satisfying (1). Since two problems have the same objective function and constraints except constraint (1), \( (x^{1*}, \hat{p}^{2*}) \) is the optimal solution of DSOCP.

\( \Rightarrow 2 \) Based on Theorem 1 and assertion 1) of Theorem 2 this assertion is easy to obtain.

\( \Rightarrow 3 \) Since \( (p^{22*}, P^{2*}, l^{2*}, v^{2*}) \) is the optimal solution of DSOCP, it also satisfies all the constraints of SSOCP. Moreover, DSOCP and SSOCP have identical objective functions, hence \( (p^{22*}, P^{2*}, l^{2*}, v^{2*}) \) is the optimal solution of SSOCP. Due to the uniqueness of optimal solution of SSOCP, we have \( (p^{22*}, P^{2*}, l^{2*}, v^{2*}) = (p^{2*1*}, P^{1*}, l^{1*}, v^{1*}) \). This completes the proof.

A. Proof of Lemma 5

Proof. With assumption A1, A2 and A4, the strong duality holds. \( (x_p^*, x_d^*) \) is the primal-dual optimal if and only if it satisfies the KKT conditions.

The Lagrangian of ESOCP is given in (B.1).
Appendix C
Proof of Theorem

Define the following function.

\[ \tilde{U}(x) = -F(x)^T \cdot (H(x) - x) - \frac{1}{2} ||H(x) - x||_2^2 + \frac{1}{2} ||x - x^*||_2^2 \]  

(C.1)

From [33], we know that \( \tilde{U}(x) \geq 0 \) and \( \tilde{U}(x) = 0 \) holds only at any equilibrium point \( x^* \).

For any fixed \( \sigma_p \), \( \tilde{U} \) is continuously differentiable as \( F(x) \) is continuously differentiable in this situation. Moreover, \( \tilde{U} \) is nonincreasing for fixed \( \sigma_p \), as we will prove in Lemma C.1. It is worthy to note that the index set \( \sigma_p \) may change sometimes, resulting in discontinuity of \( \tilde{U} \) [30]. To circumvent such an issue, we slightly modify the definition of \( \tilde{U} \) at the discontinuous points as:

1) \( \tilde{U}(x) := \tilde{U}(x) \), if \( \tilde{U}(x) \) is continuous at \( x \);
2) \( \tilde{U}(x) := \lim_{w \to x} \tilde{U}(w) \), if \( \tilde{U}(x) \) is discontinuous at \( x \).

Then \( U(x) \) is upper semi-continuous in \( x \), and \( U(x) \geq 0 \) on \( S \) and \( U(x) = 0 \) holds only at any equilibrium \( x^* = H(x^*) \).

Note that \( U \) is continuous everywhere except the switching points. Hence \( U(x) \) is nonpathological [34]. With these definitions and notations above, we can prove Theorem 7.

To prove Theorem 7, we first start with the following lemma.

Lemma C.1. Suppose A1, A2 and A3 hold. Then

1) \( U(x) \) is always decreasing along system [13].
2) the trajectory \( x(t) \) is bounded.
3) every trajectory \( x(t) \) starting from a finite initial state ultimately converges to the largest weakly invariant subset \( Z^* \) of \( Z^+ := \{ x \mid \tilde{U}(x) = 0 \} \).
4) every \( x^* \in Z^* \) is an equilibrium point of [9].

Proof of Lemma C.1. In light of Theorem 3.2 in [33], \( U(x) \) is continuously differentiable if \( F(x) \) is continuously differentiable. Its gradient is

\[ \nabla_x U(x) = F(x) - (\nabla_x F(x) - I)(H(x) - x) + x - x^* \]  

(C.2)

Then the derivative of \( U(x) \) is

\[ \dot{U}(x) = \nabla_x^T U(x) \cdot \dot{x} = \nabla_x^T U(x) \cdot (H(x) - x) \]  

(C.3)

Combining (C.2) and (C.3), we have

\[ \dot{U}(x) = -\langle F(x) + H(x) - x, (H(x) - x) \rangle + \langle x - x^*, (H(x) - x) \rangle \]
\[ = \langle F(x) + H(x) - x, H(x) - x^* + x^* - x \rangle + \langle x - x^*, H(x) - x \rangle \]
\[ = \langle F(x) + H(x) - x, (H(x) - x) \rangle - \nabla^T_x F(x) (H(x) - x) - (H(x) - x)^T \nabla_x F(x) (H(x) - x) \]
\[ = \langle F(x) + H(x) - x, H(x) - x^* \rangle + \langle x - x^*, -F(x) \rangle \]  

(C.4a)

\[ - (H(x) - x)^T \nabla_x F(x) (H(x) - x) \]  

(C.4b)

\[ = \langle F(x) + H(x) - x, H(x) - x^* \rangle + \langle x - x^*, -F(x) \rangle \]  

(C.4c)

Next, we will prove that (C.4a), (C.4b) and (C.4c) are all nonpositive. For \( \xi \) and \( \chi \), the projection has the following property [33]

\[ \langle \xi - \text{Proj}(\xi) S, \chi - \text{Proj}(\xi) S \rangle \leq 0 \quad \forall \chi \in S \]

Set \( \xi = -F(x) \), \( \chi = x^* \), then we have

\[ \langle F(x) + H(x) - x, H(x) - x^* \rangle \leq 0. \]  

(C.5)

This implies that (C.4a) is nonpositive.

Write \( x_1 := (\mu_1, \rho_{1k}, i_{ik}, \hat{p}_i) \) and \( x_2 := (\mu_i, \epsilon_i, \lambda_{ik}, \gamma_{ik}, \rho_{ik}) \), then \( L \) is convex in \( x_1 \) and concave in \( x_2 \). It can be verified that

\[ \langle x - x^*, -F(x) \rangle = -\langle x_1 - x_1^* \rangle^T \nabla^T x_1 L + \langle x_2 - x_2^* \rangle^T \nabla^T x_2 L \]
\[ \leq L(x_1^*, x_2) - L(x_1, x_2) + L(x_1, x_2^*) - L(x_1, x_2^*) \]
\[ \leq 0 \leq 0 \]  

(C.6)

This implies that (C.4b) is nonpositive.

For (C.4c), we have

\[ -(H(x) - x)^T \nabla_x F(x) (H(x) - x) = -\dot{x}^T \nabla_x F(x) \dot{x} \]
\[ \leq 0 \]  

(C.7)

where \( Q \) is given in (C.8) with

\[ M_n = \text{diag} \left( \sum_{k \in N_i} \frac{2 \rho_{ik} F_{ik}^2}{v_i^2} \right) \]

\[ T_n \times 2m(s, t) = \begin{cases} 1, & \text{if } (s, t+1) \in \mathcal{E} \text{ or } (s, t-m+1) \in \mathcal{E} \\ 0, & \text{otherwise} \end{cases} \]

\[ D_n \times 2m(s, t) = \begin{cases} -\frac{2 \rho_{i+1, t+1} P_{i+1, t+1}}{v_i^2}, & \text{if } (s, t+1) \in \mathcal{E} \\ 0, & \text{otherwise} \end{cases} \]

\[ R_n \times 2m(s, t) = \begin{cases} -\frac{P_{s+1, t+1} v_i^2}{2}, & \text{if } (s, t+1) \in \mathcal{E} \\ 0, & \text{otherwise} \end{cases} \]

\[ \tilde{I}^1_n \times 2m(s, t) = \begin{cases} 1, & \text{if } (s, t+1) \in \mathcal{E} \text{ or } (s, t-m+1) \in \mathcal{E} \\ 0, & \text{otherwise} \end{cases} \]

\[ \tilde{I}^2_n \times 2m(s, t) = \begin{cases} -1, & \text{if } (s, t+1) \in \mathcal{E} \text{ and } s \leq t \\ 0, & \text{otherwise} \end{cases} \]

\( Q \) is a semi-definite positive matrix, \( I \) is a identity matrix, the subscript implies its dimension. \( [c][d] \) denotes the diagonal matrix composed of \( c_i \) with proper dimensions. Moreover, \( Q \) can be divided into two matrices, one of which is skew-symmetric and the other is positive symmetric.

Note that the index set \( \sigma_p \) may change during the decreasing of \( U \). We have the following observations:

- The set \( \sigma_p \) is reduced, which only happens when \( P_{ik}^2/v_i - l_{ik} \) goes through zero, from negative to positive.
- Hence an extra term will be added to \( U \). As this term is initially zero, there is no discontinuity of \( U \) in this case.
The second equality holds due to (9f)-(9j). Then, we can conclude that $\dot{x}_2(t) = 0$ due to the boundedness of $x(t)$, which implies that $\mu_i, \varepsilon_i, \lambda_{ik}, \gamma_{ik}, \rho_{ik}$ are constants and $y_l = z_l = 0$ in $Z^+$. We can obtain $\dot{l}_{ik} = \dot{p}_i = 0$ from (9d), (9e) as well as the boundedness of $x(t)$.}

Combining (C.7) and (C.8), we have

$$\dot{U}(x) \leq -\dot{x}^T Q \dot{x}$$

\[=- \sum_{i \in N} (\rho_{ik}^2) \cdot \nabla_{\rho_{ik}}^2 f \cdot \dot{\rho}_{ik}^2 \sum_{i \in N} \left( \dot{P}_{ik} - \sum_{k \in N_{i}} \dot{P}_{ik} \right)^2 - 2 \rho_{ik} \left( \dot{P}_{ik} - \sum_{k \in N_{i}} \frac{|P_{ik}|}{v_i} \dot{v}_i \right)^2 - \sum_{i \in N} (\dot{v}_i + k_i \dot{p}_i - k_i \dot{v}_i)^2 \]  

(C.10)

We can directly get $\dot{\rho}_{ik}^2 = 0$ due to the A1. From $\dot{v}_i + k_i \dot{p}_i = k_i \dot{v}_i = 0$, we have $\dot{v}_i = 0$. If $\rho_{ik} > 0$, then $\dot{P}_{ik}$ is a constant, implying $\dot{P}_{ik} = 0$. If $\rho_{ik} > 0$, then $\dot{\rho}_{ik} = 0$, implying $P_{ik}$ a constant. Thus, $\dot{P}_{ik} = 0$ always holds. Consequently, we have that $\dot{x}(t) = 0$ in $Z^*$, which is the last assertion of Lemma C.1.

**Proof of Theorem 7** Fix any initial state $x(0)$ and consider the trajectory $(x(t), t \geq 0)$ of (13). As mentioned in the proof of Lemma C.1, $x(t)$ stays entirely in a compact set $\Omega_0$. Hence there exists an infinite sequence of time instants $t_k$ such that $x(t_k) \to \hat{x}^*$ as $t_k \to \infty$, for some $\hat{x}^* \in Z^*$. The 4) in Lemma C.1 guarantees that $\hat{x}^*$ is an equilibrium point of the (13), and hence $\dot{x}^* = H(\hat{x}^*)$. Thus, using this specific equilibrium point $\hat{x}^*$ in the definition of $U$, we have

$$U^* = \lim_{t \to \infty} U(x(t)) = \lim_{t_k \to \infty} U(x(t_k)) = \lim_{x(t_k) \to \hat{x}^*} U(x(t_k)) = U(\hat{x}^*) = 0$$

Here, the first equality uses the fact that $U(t)$ is nonincreasing in $t$; the second equality uses the fact that $t_k$ is the infinite sequence of $t$; the third equality uses the fact that $x(t)$ is absolutely continuous in $t$; the fourth equality is due to the upper semi-continuity of $U(x)$, and the last equality holds as $\dot{x}^* = \hat{x}^*$ is an equilibrium point of $U(x)$.

The quadratic term $(x - \hat{x}^*)^T (x - \hat{x}^*)$ in $U(x)$ then implies that $x(t) \to \hat{x}^*$ as $t \to \infty$, which completes the proof.
