Determination of optimal motion modes by energy consumption criteria can improve the efficiency of the cooling system of traction motors [1, 6-12].

The paper considers the solution of this problem for the most common motors in production now – an asynchronous traction motors (ATM) on the base of Hamilton-Jacobi-Bellman method.

The aim of the paper to improve the methodology of an electromotive railway rolling stock simulation in terms of power-optimal modes on a track with a given profile and a set motion graph.

The task of optimizing the traction drive modes. The basic states of the simulation method for the electromotive rolling stock in terms of power-optimum modes at the track with a given profile and a fixed motion graph and initial developments were described in papers [17, 18]. In this paper we present the results of further authors researches that were begun in previous works.

The determination of the ATM-SVI circuit efficiency based on the approaches proposed in the works [1, 13] is carried out, which include the following: to solve the problem of determining the optimal modes of the traction drive, four problems of the conditional optimization of the parameters of the traction drive must be solved (in acceleration modes $U_{op} = 1$, regenerative braking mode $U_{op} = 5$, maintaining mode of a given movement speed $U_{op} = 2.3$).

The efficiency of the traction drive in a certain mode of its work will be evaluated according to the criterion of maximum of its efficiency, subject to compliance with the requirements imposed by the operation modes.
Therefore, the task of determining the efficiency of the traction drive is to find the extremum of the drive factor function.

The efficiency of the traction drive (Fig. 1) can be given under the next equation:

\[
\eta_1 = \begin{cases} 
U_{op} = 1; & \eta_1 \to \max, \quad F_d \to \max, \\
U_{op} = 2; & \eta_1 \to \max, \quad F_d \to \max, \\
F_d < |F_k|; & \eta_1 \to \max, \\
v < v_{max} & F_d < 0 \quad F_d > 0 \\
F_d < |F_k|; & F_d \to \min, \\
v < v_{max} & v < v_{max} \\
F_d \to \min, & F_d < 0 \quad F_d > 0 \\
\end{cases}
\]

(1)

where \( \eta_1 \) - efficiency of the asynchronous traction motor (ATM) circuit – standalone voltage inverter (SVI), \( U_{op} \) – the operation mode of an electromotive railway rolling stock (ERRS), \( F_d \) – traction or braking force created by ERRS, \( F_k \) – limitation for engagement force of wheel-rail contact, \( v \) – railway rolling stock speed, \( v_{max} \) – constructive movement speed. \( U_{op} = 4 \) – outburst mode is an idle mode, so it is not considered in determining of drive efficiency.

For each of these tasks, it is necessary to consider two modes: the use of single-time or spatial-vector pulse-width modulation (PWM). The mode of acceleration and regenerative braking are similar. Apply the method of vector objective functions proposed in [1, 14]. As a target function for the acceleration mode, we select a vector function with the next parameters:

\[
F_{c_1} = \begin{bmatrix} 1 - \eta_1 \to \min, \\ -F_d \to \min \end{bmatrix}.
\]

(2)

The first component is chosen in such way that when it is minimized, the maximization of the efficiency of the traction drive can be obtained.

For regenerative braking mode, the vector target function has the form:

\[
F_{c_5} = \begin{bmatrix} 1 - \eta_1 \to \min, \\ F_d \to \min \end{bmatrix}.
\]

(3)

For a given speed maintaining mode we select as a target function:

\[
F_{c_3} = F_{c_4} = 1 - \eta_1 \to \min .
\]

(4)

The value of losses, and hence the efficiency of the drive, can be determined based on the slip of the traction motor, the motor voltage (phase or line) and the rotation speed. Because the operating modes are determined for all motion speeds (ATD rotation speeds), the rotation speed is a predetermined constant given in solving problem of finding the optimal traction drive operation mode.

Thus, the target functions to determine the traction drive optimal operating modes were chosen, which allow to find the optimal traction drive modes when different PWM modes are using.

The general formulation of an optimal control in real time in [13] is described.

**Software-oriented model of the ERRS motion.** As an optimization method, a combined genetic algorithm was chosen: a global search is performed by a genetic algorithm with a one-point crossover and roulette selection. At the final stage of the optimization procedure, the refinement of the optimum by the Nelder-Mead method is carried out [1, 13-19].

Let us consider the representation of the train motion equation in the program-oriented form, which will allow to use it for determination of the optimal control laws according to the Hamilton-Jacobi-Bellman method.

In this paper, the forces and supports are calculated as follows:

- Acceleration force \( F_A \) (for one time step)

\[
F_A = m \frac{v(t) - v(t - t_{step})}{t_{step}} ,
\]

(5)

where \( m \) – train weight, a conjunction;

\[
a = \frac{v(t) - v(t - t_{step})}{t_{step}} ,
\]

(6)

where \( a \) – the equivalent constant acceleration, which is subjected to a train at a speed difference \( v(t) - v(t - t_{step}) \) in one time step, due to the assumption that for each time step the acceleration is constant and the speed is linearly dependent on the time for each time step.

The main resistance to rolling \( F_{rr} \) (for one time step).

Since the velocity is linearly dependent on the time for each transition (time step), the rolling resistance for each time step can be calculated according to the average speed step and is equal to:

\[
v_{avg} = \frac{v(t) + v(t - t_{step})}{2} .
\]

(7)

Thus, the main motion resistance for each time step will be:

\[
F_{rr} = a_{rr} + b v_{avg}^2 + c v_{avg}^2 ,
\]

(8)

where \( a_{rr}, b, c \) – coefficients which for the tram car T-3 VPA with a full load 30000 kg have the following values: 1500 N, 0 Nc/m, and 1.5 Nc²/m accordingly.

As a result, the force for ERRS moving on \( t_{step} \):

\[
F_{tot} = (1 + \gamma) F_A + F_{rr} + F_s + F_k ,
\]

where \( F_s, F_k \) – resistance forces from the slopes and curves determined by the following equations:

\[
F_s = m g \frac{i}{1000} ,
\]

(10)

\[
F_k = \frac{c_{rl}}{R - r_{c1}} m ,
\]

(11)

where \( c_{rl}, c_{rl} \) – constants, determined by [15]; \( R \) – radius of the curve, \( i \) – slope, \( g \) – gravitational acceleration.

The required energy for movement on \( t_{step} \), considering the limitations and the assumption that the velocity changes linearly over time, using [15] is listed below.
For the time step from the state \( n-1 \) to the state \( n \), from the equation of equally accelerated motion, the traveled distance can be obtained by equations (13).

\[
\Delta x_n = v_{n-1} \Delta t_n + \frac{1}{2} a_n \Delta t_n^2,
\]

\[
\Delta x_n = v_{n-1} \Delta t_n + \frac{1}{2} v_n \Delta t_n - \frac{1}{2} v_{n-1} \Delta t_n \Rightarrow
\]

\[
\Delta x_n = \frac{1}{2} (v_{n-1} + v_n) \Delta t_n \Rightarrow
\]

\[
x_n - x_{n-1} = \frac{1}{2} (v_{n-1} + v_n) \Delta t_n \Rightarrow
\]

\[
x_n = x_{n-1} + \frac{1}{2} (v_{n-1} + v_n) \Delta t_n.
\]

where \( x_n, v_n, a_n \) – position of the train, its speed and acceleration at \( n \) step.

For one hour step we have:

\[
x_f = x_{f-\text{tstep}} + \frac{1}{2} (v_{f-\text{tstep}} + v_f) \text{tstep},
\]

where \( x_f \) – final position of the train for one \( \text{tstep} \);

\( x_{f-\text{tstep}} \) – the initial position of the train for one \( \text{tstep} \).

Expression (14) gives the final position of the train for transfer, when the initial position, the initial and final velocities are known, as well as the value of the time step.

Thus, the resulting equations (12 – 14) allow to improve the simulation method of the electromotive rolling stock in terms of energy optimum modes.

The solution of the traffic modes optimization problem for the track section from the tram depot «Saltovske» to the turning circle of 602 district in Kharkiv and in the reverse direction was carried out. The results of solving the traction problem with tram traffic in optimal mode on Fig. 2 are shown. According to the results of solving the traction problem, the losses in the elements of the traction motor design on Fig. 3 are shown.

By means of a comparative analysis of experimentally determined and computing traction characteristics and efficiency values, the adequacy of the proposed mathematical model for the drive efficiency determination of the was established.

The maximum deviation in the calculation of losses is 7.42 %, which is quite acceptable for the carried-out calculations.
Fig. 2. The solution results of the traction movement task for the tramcar T-3VPA with traction motor AD931 on the track section from the tram depot «Saltovske» to the turning circle of 602 district in Kharkiv and in the reverse direction:
1 – movement speed (v), km/h; 2 – speed limitation, km/h; 3 – traction force (F_r), kN; 4 – movement time (t), min; 5 – losses (E), kW·h

Fig. 3. Loses in traction motor: 1 – core loss (P_1), W; 2 – rotor loss (P_2), W; 3 – copper losses in stator winding at a slot part (P_3), W;
4 – copper losses in stator winding at a front part (P_4), W; 5 – mechanical losses (P_5), W
Conclusions.
1. Using the genetic algorithm and the Yakobi-Hamilton-Belman method the calculated ratios for the determination of the railway electromotive traction drive efficiency are obtained. On this base the methodology of ATM motion simulation during the movement of the electromotive rolling stock according to the power-optimal regimes on the track section with the given graph and the set motion schedule is improved.
2. The adequacy of the obtained equations, which determine the efficiency both the maximum efficiency value of the ATM-SVI circuit in different operating modes under the coupling constraints, and constructive speed, is confirmed by the results of the experiment on the section of the tramway from the depot «Saltovskе» to the turning circle of 602 district in Kharkiv. The maximum deviation in the calculation of losses does not exceed 7.42%.
3. According to the results of solved traction problem, the change in losses in the elements of the traction tram traction design was first determined.
4. The use of advanced methodology is proposed to be carried out in advance based on solving the problem of work modes conditional optimization.
