ABSTRACT

We study the general non-minimally coupled charged massive spin 3/2 model both for its low energy phenomenological properties and for its unitarity, causality and degrees of freedom behaviour. When the model is viewed as an effective theory, its parameters (after ensuring the correct excitation count) are related to physical characteristics, such as the magnetic moment \(g\) factor, by means of low energy theorems. We also provide the corresponding higher spin generalisation. Separately, we consider both low and high energy unitarity, as well as the causality aspects of our models. None (including truncated \(N = 2\) supergravity) is free of the minimal model’s acausality.

Keywords: Rarita–Schwinger equation, higher spin, supergravity, low energy theorems, causality, unitarity.
1 Introduction

Gauge interactions of massive (let alone massless) relativistic higher spin fields constitute an ancient and difficult subject. Whatever the formal problems these models encounter, effective higher spin theories must be constructible since approximately localised higher spin particles exist. Such models should achieve low energy consistency, and share some of the physical properties described by their lower spin hadronic physics counterparts.

The proper framework for describing relativistic interactions is the action principle. In our present study of charged massive higher spins we seek only effective (rather than renormalisable) actions, which can in general possess dimensionful, non-minimal, couplings beyond the minimal prescription, unique in first order systems, $\partial_\mu \to \partial_\mu + i e A_\mu$. In particular, the associated coupling constants will determine $2s+1$ intrinsic multipole moments of a spin $s$ particle (charge, magnetic dipole, quadrupole and octupole for $s = 3/2$).

The more formal properties, such as unitarity and causality, of higher spin models will in general also depend upon details of the non-minimal couplings. Some of the important affected issues include: (i) A gyromagnetic ratio $g = 2$ is required by the optical and low energy theorems, at least for for pure electromagnetic interactions $[1]$, on the other hand, minimal coupling implies $g = 2/3$ $[2]$. (ii) Tree unitarity $[3]$ requires the non-minimal couplings of (truncated) $N = 2$ supergravity $[4]$. (iii) Quantisation of the minimal theory is problematic since the fundamental canonical commutator becomes indefinite beyond a critical value of the magnetic field $[5]$, or equivalently the model exhibits acausal propagation $[6]$. However, if the minimal electromagnetic interactions are extended to include gravity as obtained by dropping only the cosmological constant term of $N = 2$ anti-de Sitter supergravity $[7]$, causality is restored $[8]$. Unfortunately, this formally consistent model is unsuitable for phenomenological applications, since it tunes spin $3/2$ and Planck masses.

In this paper, we study the low energy behaviour, unitarity and causal consistency of general flat space non-minimal, non-derivative, couplings, concentrating on the massive charged spin $3/2$ system, the simplest theory subject to the array of higher spin subtleties. Of the five independent non-minimal terms linear in the field strength, two are eliminated by a simple degrees of freedom (DOF) consistency requirement. One of the three remaining couplings does not contribute to photon emission and Compton scattering.
but is included in our causality analysis. We employ low energy theorems (LETs) to identify the leading low energy non-minimal coupling as a magnetic moment interaction and compute the gyromagnetic ratio $g$ in terms of the parameters in the action. The generalisation of this result to higher multipoles will be treated elsewhere [9]; its higher spin analogue is given in Appendix A.

The gyromagnetic ratio $g$ in our models is arbitrary and thus they are perfectly suited for phenomenological applications where neither the pure electromagnetic $g = 2$ unitarity requirement nor tree unitarity need apply. Loss of the latter merely signals the scale at which the effective description ceases to be valid.

Study of causality yields a negative result; like the minimal model, ours all permit acausal propagation for critical electromagnetic fields. [In [8] causality is preserved by taking gravity and electromagnetism not merely external, but dynamical; we hope to include curved space elsewhere [4].] Nevertheless, we will argue that for perturbative processes, formulated in terms of free asymptotic fields, neither high energy unitarity nor causality problems spoil the validity of the models as a phenomenological tool.

In section 2 we present the non-minimal models under consideration and obtain the constraints required by a correct DOF count. Section 3 contains the verification of the LETs for the soft photon vertex and Compton scattering, along with our gyromagnetic ratio computation. A study of causality is presented in section 4. In section 5 we summarise and discuss our work. The generalisation of our soft photon vertex results and identification of the magnetic moment for higher spins is given in Appendix A and the extension of our causality analysis to the most general non-minimal couplings is given in Appendix B.

2 The Model

We begin with the Lagrangian for the complex vector-spinor Rarita–Schwinger field $\psi_\mu$,

$$\mathcal{L} = -\bar{\psi}^\mu \gamma_{\mu\nu\rho} D^\nu \psi^\rho - \frac{ie}{m} \bar{\psi}_\mu F^{\mu\nu} \psi^\nu;$$

(1)

$$\bar{\psi}_\mu F^{\mu\nu} \psi^\nu \equiv l_1 \bar{\psi}_\mu F^{\mu\nu} \psi^\nu + l_2 \bar{\psi}_\mu \tilde{F} \psi^\mu$$
\[ + l_3 F^{\mu\nu} [\overline{\psi}_\mu \gamma_\nu \gamma_\psi + \overline{\psi}_\mu \gamma_\mu \psi_\nu] + l_4 \overline{\psi}_\mu \gamma_\mu \overline{F} \gamma_\psi + il_5 F^{\mu\nu} [\overline{\psi}_\mu \gamma_\nu \gamma_\psi - \overline{\psi}_\mu \gamma_\mu \psi_\nu]. \] (2)

Our conventions are: Metric \( \eta_{\mu\nu} = \text{diag}(-, +, +, +) \), \( \mu, \nu, \ldots = 0, \ldots, 3, i, j, \ldots = 1, \ldots, 3 \); Dirac matrices: \( \{\gamma^\mu, \gamma^\nu\} = 2 \eta^{\mu\nu}, \gamma^\mu \gamma^\nu = \gamma^0 \gamma^\mu \gamma^0; \gamma^{\mu_1 \ldots \mu_n} \equiv \gamma^{[\mu_1} \ldots \gamma^{\mu_n]} \) (we always (anti)symmetrise with unit weight); \( \gamma^5 = -i\gamma^{0123}, \gamma^{\mu\nu\rho\sigma} = i\gamma^5 \epsilon^{\mu\nu\rho\sigma} \). Contraction of all indices of a tensor with Dirac matrices is denoted by a hat, e.g., \( \hat{F} = F^{\mu\nu} \gamma_\mu \gamma_\nu \). The operator in the minimal term of (1)

\[ D_\mu \equiv D_\mu + \frac{1}{2} m \gamma_\mu, \quad D_\mu \psi_\nu = \partial_\mu \psi_\nu + ieA_\mu \psi_\nu \] (3)

also incorporates the usual mass term \( m \overline{\psi}_\mu \gamma_\mu \psi_\nu \); it satisfies

\[ [D_\mu, D_\nu] = ieF^{\mu\nu} + \frac{1}{2} m^2 \gamma_{\mu\nu}, \quad [D_\mu, \gamma_\nu] = m \gamma_{\mu\nu}. \] (4)

Note that \( il_5 F^{\mu\nu} [\overline{\psi}_\mu \gamma_\mu \gamma_\psi - \overline{\psi}_\mu \gamma_\mu \psi_\nu] \), being diagonal in a Majorana basis, is non-vanishing even for an uncharged real field; on-shell (where \( \gamma_\psi = 0 \)) it does not contribute at lowest perturbative orders and we therefore drop it until the general causality analysis in section 4.

The set (2) represents the most general non-derivative, hermitean, parity-even couplings linear in the field strength \( F^{\mu\nu} \). That they must constitute a five parameter family can also be seen upon expanding the most general possible \( \overline{\psi}_\mu \Gamma^{\mu\nu\rho\sigma} \psi_\nu F^{\rho\sigma} \) in a Fierz basis: There is a single coupling to \( \gamma^{\mu\nu\rho\sigma} \), three possibilities for \( \gamma^{\mu\nu} \) and a single scalar 11 coupling. Thus the \( \gamma^5 \overline{F}^{\mu\nu} \) of supergravity \( \overline{F}^{\mu\nu} \equiv (1/2) \epsilon^{\mu\nu\rho\sigma} F^{\rho\sigma} \) may be cast in the above basis as

\[ \overline{\psi}_\mu i\gamma^5 \overline{F}^{\mu\nu} \psi_\nu = \overline{\psi}_\mu F^{\mu\nu} \psi_\nu - \frac{1}{2} \overline{\psi}_\mu \overline{F} \psi^\mu \]

\[ - F^{\mu\nu} [\overline{\psi}_\mu \gamma_\nu \gamma_\psi + \overline{\psi}_\nu \gamma_\gamma \gamma_\mu \psi_\nu] + \frac{1}{2} \overline{\psi}_\nu \gamma_\psi \hat{F} \gamma_\psi. \] (5)

Two of the five parameters in (1,2) may be eliminated by requiring that the model describe the correct DOF or, equivalently, maintains the constraint count of the free theory: The zeroth component of the equation of motion \( R_0 = \delta L / \delta \overline{\psi}^0 \) involves no time derivatives and is therefore a constraint eliminating four of the sixteen (complex) components of \( \psi_\mu \). Another constraint eliminating four more components is still required before one can conclude
that on-shell half of the remaining components yield $2s + 1 = 4$ physical DOF. When $\psi_0$ appears linearly in the action, as for the minimal theory, it is a Lagrange multiplier imposing the constraint $R_0 = 0$. Requiring its preservation under time evolution, $\dot{R}_0 = 0$, yields the necessary additional constraint. If instead $\psi_0$ appears quadratically (i.e., as $\psi_0^\dagger M \psi_0$ for some matrix $M$) the $R_0 = 0$ equation now determines $\psi_0$, and requiring $\dot{R}_0 = 0$ yields an equation of motion for $\dot{\psi}_0$. This choice describes too few constraints/too many (propagating) DOF, as compared to the free field.

One non-minimal model respecting the DOF count is the truncation of $N = 2$ supergravity with the cosmological, curvature and four-Fermi terms omitted\footnote{This truncation should not be confused with the supersymmetry-preserving anti-de Sitter-Poincaré contraction, mapping the model of \cite{Bianchi:2015dpa} to the original $N = 2$ model \cite{Bianchi:2015kia}. The latter has a flat gravitational background and only non-minimal, uncharged, Maxwell couplings.}. It corresponds by (5) to the choice of parameters $l_1 = -2, l_2 = 1/2, l_3 = 1, l_4 = -1/2$ (and $l_5 = 0$) reproducing $\mathcal{F}_{\mu\nu} = -(F_{\mu\nu} + i\gamma^5 \tilde{F}_{\mu\nu})$. If however, as in \cite{Bianchi:2015dpa}, the further truncation excluding the gamma-trace components of $\psi_{\mu}$ in the non-minimal sector is made, the DOF count is violated. This fact would seem to make moot the causality claim there.]

Henceforth, we retain only models linear in $\psi_0$, which, as is easily seen, is equivalent to demanding $\mathcal{F}_{\mu\nu} = -\mathcal{F}_{\nu\mu}$. The corresponding relations amongst parameters are

$$l_2 + l_4 = 0, \quad l_3 + 2l_4 = 0,$$

and the non-minimal interactions reduce to the two combinations (dropping $l_5$)

$$\overline{\psi}_{\mu} \mathcal{F}^{\mu\nu} \psi_{\nu} = [l_1 + 2l_2] \overline{\psi}_{\mu} F^{\mu\nu} \psi_{\nu} - 2l_2 \overline{\psi}_{\mu} i\gamma^5 \tilde{F}^{\mu\nu} \psi_{\nu}. \quad (7)$$

We now consider the properties of these physical spin 3/2 theories.

### 3 Low Energy Theorems

LETs characterise soft photon scattering amplitudes in terms of the mass, charge and magnetic moment of the target \cite{Bianchi:2015dpa, Bianchi:2015kia, Bianchi:2015kia}, independent of its internal structure, relying only on gauge and Lorentz invariance plus low photon frequency. In this sense, LETs are purely kinematical and, irrespective of any causal pathologies, perturbative scattering amplitudes formulated...
in terms of free asymptotic fields are guaranteed to satisfy them. Therefore
LETs provide a simple way to map our parameters to the physical ones.

We first study the vertex for the emission of a single low frequency photon, then Compton scattering with small incoming (and outgoing) photon frequencies. In each case the relevant LETs are usually stated for stationary targets and Lorentz invariance is not manifest. So we first enunciate the dictionary with our relativistic Feynman tree amplitudes. A soft photon is invariably defined by the requirement that
\[
\frac{\omega^a}{m} \equiv -\frac{p.k^a}{m^2} \ll 1, \quad (8)
\]
for photon a’s four-momentum \(k^a_\mu\) and target \(p_\mu\). In the laboratory frame \(p_\mu = (m, 0, 0, 0)\), \(\omega^a\) reduces to the usual photon frequency.

For each photon polarisation \(\varepsilon^a_\mu\) we employ Feynman gauge \(k^a.\varepsilon^a_\mu = 0\) along with the residual gauge fixing condition \(p.\varepsilon^a_\mu = 0\) so that in the lab. frame one has \(\varepsilon^a_\mu = (0, \hat{\varepsilon}^a_\mu)\) and \(\hat{k}^a.\hat{\varepsilon}^a_\mu = 0\). We also utilise a covariant notation for the target polarisations \(u^\rho\) and \(u'^\rho\) with \(u^\rho_{\mu} = u^\rho_{\mu}(p)\) and \(u'^\rho_{\mu} = u'^\rho_{\mu}(p')\) where \(p'_\mu\) is the outgoing momentum of the target particle and the usual asymptotic on-shell conditions hold
\[
p.\gamma = 0 = (i\gamma^\mu + m)u_\mu, \quad \gamma^\rho p' = \gamma^\rho 0 = \gamma^\rho = 0 = \gamma^\rho (i\gamma^\mu + m). \quad (9)
\]

An explicit representation for the spin 3/2 polarisations in terms of the usual massive spin 1 and spin 1/2 polarisations \(\varepsilon^I_\mu (l = -1, 0, 1)\) and \(u^s (s = -1/2, 1/2)\), respectively, is given by \(u^\pm_{\mu} = \varepsilon^\pm_\mu u^{\pm1/2}\) and \(u^{\pm1/2} = (\varepsilon^{\pm1} u^{\pm1/2} + \sqrt{2}\varepsilon^0 u^{\pm1/2})/\sqrt{3}\) [13]. Obviously, inserting \(u^\rho_{\mu} = u^\lambda_{\mu}\) and \(u'^\rho = u'^\lambda\) with \(\lambda, \lambda' = -3/2, 1/2, 1/2, 3/2\) in (12) below, \(M^{\mu\nu}_{\lambda\lambda'}\) (regarded as a matrix in the labels \(\lambda\) and \(\lambda'\)) is a spin 3/2 irreducible representation of the Lorentz algebra.

The total spin matrix \(S\) is, as usual, the dual of the (spatial) Lorentz generators, \(S^i = \frac{i}{2}e^{ijk}M_{jk}\), and the Lorentz generators act on the relativistic vector-spinor on-shell representation of the spin 3/2 polarisations \(u^\rho\) according to
\[
M^{\mu\nu}_{\rho\sigma} = \frac{1}{2} \gamma^{\mu\nu} \delta^\rho_\sigma + 2 \delta^{[\mu\rho]} \delta^{\nu]\sigma}, \quad (10)
\]
so that
\[
\delta_{\text{Lorentz}}u^\rho = \frac{1}{2} \lambda_{\mu\nu} M^{\mu\nu}_{\rho\sigma} u^\sigma = \lambda^\rho_{\sigma} u^\sigma + \frac{1}{4} \hat{\lambda} u^\rho. \quad (11)
\]
It is useful to define
\[ \mathcal{M}^{\mu\nu} \equiv \bar{u}_\rho M^{\mu\nu\rho}_\sigma u^\sigma = \frac{1}{2} \bar{u}_\rho \gamma^{\mu\nu} u^\rho + 2 \bar{u}^{[\mu} u^\nu] \] \[ \mathcal{S}^i \equiv \frac{i}{2} \epsilon^{ijk} \bar{u}_\rho M_{jkl\sigma} u^\sigma. \]

(12)

The LET for the photon vertex states that the amplitude for emission of a soft photon by a stationary mass \( m \), spin \( s \) “target” is
\[ T_{fi} = -\frac{i\mu}{s} (\vec{e} \times \vec{k}) \cdot \vec{S} + O(\omega^2); \]
transparent derivations of (13) and (15) below may be found in [1]. The magnetic moment \( \mu \) appearing in (13) is related to the charge/mass ratio of a spin \( s \) particle by the gyromagnetic ratio \( g \), defined by
\[ \mu \equiv \frac{egs}{2m}. \]

(14)

The standard LET for Compton scattering reads
\[ T_{fi} = -\frac{e^2}{m} \bar{e}' \cdot \vec{e}' \bar{u}_\rho u^{\rho} + \frac{ie\omega}{m} \left( \frac{2\mu}{s} - \frac{e}{m} \right) (\vec{e}' \times \vec{e}) \cdot \vec{S} \]
\[ -\frac{ie\mu}{\omega s} \left( \vec{e} \cdot \vec{k}' (\vec{e}' \times \vec{k}') - \vec{e}' \cdot \vec{k} (\vec{e} \times \vec{k}) \right) \cdot \vec{S} \]
\[ -\frac{i\mu^2}{\omega s^2} ((\vec{e}' \times \vec{k}') \times (\vec{e} \times \vec{k})) \cdot \vec{S} + O(\omega^2). \]

(15)

Our task now is to derive the amplitudes (13) and (15) in a Lagrangian framework and thereby relate the parameters of (1,7) to the physical ones which, (apart from \( e \) and \( m \)) means the single number \( g \).

### 3.1 The Soft Photon Vertex

The amplitude (13) may, using the on-shell conditions for the target and soft photon polarisations, be expressed in the manifestly Lorentz invariant form
\[ T_{fi} = \frac{i\mu}{2s} F_{\mu\nu} \mathcal{M}^{\mu\nu} + O(\omega^2), \quad F_{\mu\nu} = i(k_\mu \epsilon_\nu - k_\nu \epsilon_\mu). \]

(16)

On-shell the interaction Lagrangian, including minimal and non-minimal couplings, becomes
\[ i\mathcal{L}^{\text{int}} |_{\text{on-shell}} = iT_{fi} = e \bar{\pi}_\rho \phi^{\rho} u^\rho + \frac{e}{m} \left[ l_1 \bar{\pi}_\mu F^{\mu\nu} u_\nu + l_2 \bar{\pi}_\rho \hat{F}^\rho u^\rho \right]. \]

(17)
The asymptotic Rarita–Schwinger equation may be used to derive the obvious generalisation
\[ \bar{\pi}_\rho(p') \gamma^\mu u_\sigma(p) = -\frac{i}{2m} (p + p')^\mu \bar{\pi}_\rho u_\sigma + \frac{i}{2m} (p' - p)_\nu \bar{\pi}_\rho \gamma^\mu u_\sigma \] (18)
of the spin 1/2 Gordon identity. Thus the amplitude derived from the non-minimal Lagrangian reads
\[ T_{fi} = -\frac{ie}{2m} \left( 2l_1 \bar{\psi}_\mu F^\mu\nu u_\nu + \frac{1}{2} (4l_2 - 1) \bar{\pi}_\rho \hat{F}_\rho u^\rho \right). \] (19)

At this juncture, the amplitude seems quite different from that of a pure \( s = 1/2 \) system for which there is a one parameter family of \( (g - 2) \) values read off from the \( \hat{F} \) term with, of course, no counterpart to the \( l_1 \) term. If the latter is to augment the \( \hat{F} \) term to a coupling involving the full Lorentz generators as in (12), the relevant coefficient between the two terms must be 1/4. There must be, therefore, an identity relating these two terms for the LET to hold and this is indeed the case (see (21) below). Alternatively, it is possible, for the choice of parameters \( l_1 = -g/2 = 4l_2 - 1 \) to directly satisfy the LET, in which case the Lagrangian then reads
\[ \mathcal{L} = \mathcal{L}_{\text{Min}} + \frac{i e}{m} \bar{\psi}_\mu F^\mu\nu \psi_\nu + \frac{ie(g - 2)}{4m} F_{\mu\nu} \bar{\psi}_\rho M^{\mu\nu,\rho} \psi_\sigma \]
\[ + \frac{ie(g - 2)}{4m} \left( F^{\mu\nu} \left[ \bar{\psi}_\mu \gamma_\nu \gamma.\psi + \bar{\psi}.\gamma_\mu \psi_\nu \right] - \frac{1}{2} \bar{\psi}.\gamma \hat{F} \gamma.\psi \right). \] (20)

Together, the first two terms of \( \mathcal{L} \) produce a \( g = 2 \) coupling since the minimal Lagrangian gives the spin 1/2 part of the Lorentz generators via the Gordon identity above and the non-minimal coupling to \( F^{\mu\nu} \) yields the spin 1 contribution (exactly the same term required for a spin 1 vector boson to have \( g = 2 \)). The third term is a direct coupling to the total Lorentz generators and yields an anomalous magnetic moment coupling, the remaining ones being required to ensure the correct DOF in the \( g \neq 2 \) case. One might speculate whether this theory may be physically more desirable for higher order processes not completely determined by LETs. It is interesting to further note that it does not include truncated \( N = 2 \) supergravity.

Since LETs are just a statement about parts of amplitudes determined completely by kinematics, they should be reproduced for any choice of pa-
rameters. The on-shell identity
\[
\bar{u}'_\rho(p') \gamma_{\mu\nu} u'^\nu(p) = 2 \bar{u}'_\mu(p') u_\nu(p) + \mathcal{O}(\omega)
\] (21)
is easily verified in the frame \( p_\mu = (m, 0, 0, 0) \). This low energy equality states that on-shell the spin 1/2 and spin 1 parts of the Lorentz generators may be traded against one another. Hence the low energy result is precisely reproduced by any of the non-minimal Lagrangians, the gyromagnetic ratio being
\[
g = \frac{2}{3} - \frac{4}{3} (l_1 + 2l_2),
\] (22)
a sum of minimal and non-minimal contributions. The model in (20) is clearly a sub-case of this result. For minimal coupling the well known result \( g = 1/s = 2/3 \) emerges \[2\]. Observe, that the parameters, \( l_1 = -2 \) and \( l_2 = 1/2 \), of truncated \( N = 2 \) supergravity also yield \( g = 2 \) \[4\]. Finally, we note, in passing, that in the basis \[7\] only the \( F_{\mu\nu} \) coupling contributes to the gyromagnetic ratio (22), independent of the \( i\gamma^5 \tilde{F}_{\mu\nu} \) term. This is not surprising since \( \gamma^5 \) mixes the “large” and “small” components of the vector-spinor \( u_\mu \) defined by projection with respect to \( i\gamma^0 \), and is higher order in the soft photon expansion. This term will contribute to higher quadrupole and octupole moments. The extension of our work to such moments is an interesting but separate issue.

### 3.2 Compton Scattering

A useful check on our vertex result (22) is to compute the amplitude for Compton scattering. In particular, since the gyromagnetic ratio must be precisely \( g = 2 \) for the optical theorem to hold \[1\], the latter will produce an additional relation between the parameters \( l_1 \) and \( l_2 \).

Let us denote incoming and outgoing photon momenta by \( k_\mu \) and \( k'_\mu \), respectively; the mass shell condition \( p'^2 = -m^2 \) implies that the difference \( \omega' - \omega = k.k'/m \) is second order in this expansion. Therefore we eliminate

\[\text{In \[7\] the Thompson limit for Compton scattering was obtained in the truncated \( N = 2 \) supergravity model, a calculation that seemed to hinge on delicate cancellations due to the particular form of the supergravity non-minimal couplings. However, since the Thompson limit is dictated by the lowest order LET, our generic computation always guarantees this result.}\]
\[ \omega' (\text{using this relation}) \text{ and } p' \text{ (by momentum conservation)}; \text{ one can then evaluate the order of any expression simply by counting the number of four-vectors } k \text{ and } k' \text{ in it.} \]

We now evaluate the relevant \( s \) and \( u \) channel diagrams of Figure 1 in this limit, using the vertices of (1) and the free propagator

\[
S^F_{\mu\nu}(p) = \frac{-i}{p^2 + m^2} \left[ (\eta_{\mu\nu} + \frac{p_\mu p_\nu}{m^2})(i\gamma_\mu - m) + \frac{1}{3} \left( \frac{i p_\mu}{m} - \gamma_\mu \right)(i\gamma_\nu + m)(\frac{i p_\nu}{m} - \gamma_\nu) \right].
\]

To extract the leading and next-to-leading terms in the low energy expansion of the amplitude, we need the Gordon identity (18) of the previous section along with the following generalisation,

\[
\pi'_\lambda(p') \gamma^{\mu\nu} u_\kappa(p) = -\frac{3i}{2m} (p + p')^{[\mu} \pi'_\lambda \gamma^{\nu]} u_\kappa + \frac{i}{2m} \pi'_\lambda \gamma^{\mu\nu\sigma} u_\kappa \left( p' - p \right)_\sigma.
\]

Note that in the lab. frame, the “Dirac” equation (9) reads \( \gamma^0 u = i m u \) and using the above Gordon identities, expressions such as \( \pi'_\mu \gamma^{\mu\nu} \epsilon_\mu k_\nu u_\sigma \) are effectively equal to \( \pi'_\mu \gamma^{\mu\nu} \epsilon_\mu k_\nu u_\sigma \) at leading order in the low energy expansion. As a simple gauge invariance check, before imposing the residual gauge choice \( p.\epsilon = 0 = p.\epsilon' \) and taking the low energy limit, we verified that our amplitude satisfies transversality in each photon line separately.

Once again, applying only the Gordon identities (18) and (24), the amplitude satisfies the LET only for the choice of parameters of the Lagrangian (20).
However, once one applies further the on-shell identity (21) along with the additional identity (equivalent to (21) upon contracting indices $\mu$ and $\sigma$)

$$\mathcal{T}^{[\mu} \gamma_{\nu]} [\rho u_{\sigma}] = \mathcal{T}^{[\rho} \gamma_{\sigma]} [\mu u_{\nu}] + \mathcal{O}(\omega)$$

one finds for the amplitude (in an obvious matrix notation for vector indices)

$$T_{fi} = -\frac{e^2}{m} \mathcal{T} . u \varepsilon' \cdot \varepsilon + \frac{e^2}{4m^3} (g - 2)^2 p . k (\varepsilon' . \mathcal{M} . \varepsilon)
- \frac{i e^2 g}{4m p . k} [\text{tr} (F'.\mathcal{M}) \varepsilon . k' - \text{tr} (F.\mathcal{M}) \varepsilon' . k]
+ \frac{e^2 g^2}{4m p . k} \text{tr} (F'.\mathcal{M} . F) + \mathcal{O}(\omega^2)$$

where, as in the previous section $g$ stands for the combination (22) of parameters $g = 2/3 - 4/3 (l_1 + 2l_2)$. It is not difficult to verify that in the lab. frame, the amplitude (26) precisely reproduces the LET (15).

### 3.3 Unitarity and $g = 2$

We close this section with some comments on unitarity. As mentioned, low energy unitarity imposes the value $g = 2$ for any spin [1]. The idea is that, (for a particle interacting electromagnetically only), the optical theorem constrains the low energy forward ($k = k'$) limit of the scattering amplitude (15)

$$T_{fi} = -\frac{e^2}{m} \varepsilon' \cdot \varepsilon \mathcal{T} . u
- \frac{i e^2 \omega}{4m^2} (g - 2)^2 (\varepsilon' \times \varepsilon) \cdot \mathcal{S} + \mathcal{O}(\omega^2)$$

(27)

to have no contribution linear in $\omega$, thus requiring $g = 2$. Clearly, if one wishes to apply this criterion to our model, one can simply take the choice of parameters $l_1 + 2l_2 = -1$. Of course, in reality, one may be interested in an effective description of a composite particle participating in the strong interactions with $g \neq 2$. Here the models with general values of $g$ are suitable.

The quite distinct criterion of tree unitarity [3, 15, 4] concerns the high energy behaviour of the theory. Partial wave amplitudes are subject to (constant) unitarity bounds which may, in principle, be violated by tree level amplitudes. For effective theories these bounds determine the energy scale at which the effective description fails and new physics enters (e.g., inapplicability of the Fermi weak interaction theory beyond $m_W$). This argument
does not, however, rule out the low energy applicability of the effective theory. The failure of tree unitarity in the minimal model was first observed in [15]. [Their inference of a connection between this and acausality seems unwarranted, however, given that the $g = 2$ tree unitary model also fails to propagate causally.] Let us, nonetheless, review the tree level unitarity argument [15, 4] in more detail. Massive higher spin propagators such as (23) contain inverse powers of the mass. In tree level Green functions, for general kinematical configurations where all momenta are large, these terms lead to contributions growing with positive powers of the energy $E$. In addition to being dangerous for renormalisability when higher order loops are constructed from trees, they eventually violate partial wave unitarity bounds. There is, however, a quite general mechanism related to gauge invariance to remove this undesirable high energy behaviour. Namely, if one investigates the worst powers of inverse mass in the propagator (23)

$$\frac{2}{3} \frac{p_\mu p_\nu}{m^2} \left(\frac{1}{p^2 + m^2}\right)$$

one see that the operators $p_\mu$ and $p_\nu$ generate a linearised gauge transformation (in our case a linearised local supersymmetry transformation)

$$\delta \psi_\mu = \partial_\mu \varepsilon$$

at the vertices to which the propagator is attached. Hence requiring the on-shell vertices to satisfy the appropriate supersymmetric Ward identity will lead to cancellation of $1/m^2$ contributions. Obviously one can apply this procedure to further constrain the non-minimal couplings. The supergravity solution with $l_1 = -2$ and $l_2 = 1/2$ uniquely satisfies this criterion via the usual supersymmetry Ward identity (the parameters $l_3$ and $l_4$ remain undetermined since $\gamma.\psi = 0$ on an external line) and in this sense the supergravity-inspired model may be favoured amongst possible models although, as argued above, at the more phenomenological level of effective theories this choice is not particularly compelling.
4 Causality and Quantisation

As we shall discuss, a study of causality amounts to investigating whether the constraints, required to ensure the correct physical DOF, are consistent. In particular, one may find that, for some critical value of the external field $F_{\mu
u}$, the secondary Lagrangian constraint may no longer be inverted to solve for the Lagrange multiplier variable $\psi_0$. From a canonical viewpoint, this implies that the Dirac bracket governing dynamics on the constraint surface is ill-defined at this point [5] and yields a pathology that, of course, extends to the corresponding quantum mechanical canonical commutators. In terms of the field equations, this pathology implies that the model permits superluminal propagation [6]. A brief review of the precise relation between causality breakdown and consistency of constraints is given at the end of this section.

The key point is to find, and study the consistency of, eight (complex) constraints amongst the sixteen field components $\psi_\mu$; the equations of motion then reduce these to four physical DOF.

The field equation derived from (1) is
\[ R_\mu \equiv \frac{\delta S}{\delta \psi_\mu} = \gamma_{\mu\nu\rho} D^\nu \psi_\rho + \frac{ie}{m} F_{\mu
u} \psi_\nu = 0. \]  
(30)

Since $R_0$ does not involve time derivatives of any fields
\[ \Theta_1 = \gamma^0 R_0 = \gamma_{ij} D^i \psi^j + \frac{ie}{m} \gamma_0 F_{0i} \psi_i = 0. \]  
(31)
is a primary constraint. As explained in section [2] a correct DOF count requires that $F_{00} = 0$ so that (31) does not determine the Lagrange multiplier $\psi_0$.

Before taking the divergence of $R_\mu$ to determine the secondary constraint we employ the relation (equivalent to (31) on-shell)
\[ \gamma \cdot R = 2 (\gamma \cdot D - 3m) \gamma \cdot \psi - 2 D \cdot \psi + \frac{ie}{m} \gamma \cdot F \cdot \psi = 0 \]  
(32)

Our terminology is as follows: For a first order system devoid of gauge invariances, the primary (Lagrangian) constraints are simply any field equations without time derivatives. Requiring that the primary constraints are preserved by time evolution leads to secondary constraints and so forth. Precisely the same constraints arise as second class secondary and tertiary constraints, respectively, in a canonical Dirac analysis [7].
to rewrite the field equations $R_\mu$ as

$$R_\mu = (\mathcal{D} - m)\psi_\mu - (\mathcal{D}_\mu - \gamma_\mu [\mathcal{D}, 2m]) \gamma_\psi - \gamma_\mu \mathcal{D}_\psi + \frac{ie}{m} F_{\mu\nu}\psi^\nu$$

$$= (\mathcal{D} - m)\psi_\mu - (\mathcal{D}_\mu - m\gamma_\mu) \gamma_\psi + \frac{ie}{2m} \gamma_\nu \gamma_\mu F^{\nu\rho}\psi_\rho = 0. \quad (33)$$

In particular, in temporal gauge $A_0 = 0$, the equations of motion for the spatial components of the Rarita–Schwinger field are

$$\gamma_0 R_i = \dot{\psi}_i + \gamma_0 (\vec{D} - \frac{1}{2}m) \psi_i - \mathcal{D}_i \gamma_0 \gamma_\psi + \frac{ie}{2m} \gamma_0 \gamma_\gamma_\gamma F^{\nu\rho}\psi_\rho = 0. \quad (34)$$

We now obtain a secondary Lagrangian constraint from

$$\Theta_2 = \mathcal{D} R = \frac{3}{2} m^2 \gamma_\psi + \frac{ie}{2} \gamma_{\mu\nu}\psi_\mu F^{\nu\rho}\psi_\rho + \frac{ie}{m} \mathcal{D}_i \mathcal{F}_\psi$$

$$= \frac{3}{2} m^2 \gamma_\psi + \frac{ie}{2} \gamma_{\mu\nu}\psi_\mu F^{\nu\rho}\psi_\rho + \frac{ie}{m} (\mathcal{D}_i \mathcal{F}_\nu + \frac{1}{2} m \gamma_0 \mathcal{F}_{0\nu}) \psi_\nu$$

$$+ \frac{ie}{m} (\mathcal{F}_0 \psi_i + \mathcal{F}_0 \psi_i) = 0; \quad (35)$$

since $\dot{\psi}_i$ may be eliminated via $(34)$, $\Theta_2$ constitutes a second independent algebraic relation amongst field components. [Again, observe that $(35)$ would contain a term $(ie/m) F_{00}\psi_0$ for $F_{00} \neq 0$ and become an equation of motion rather than a constraint.]

Upon substituting $(34)$ into $(33)$ we concentrate on the coefficient matrix of the Lagrange multiplier $\psi_0$ in $\Theta_2$, since $\psi_0$ must be determined by this relation:

$$\Theta_2 \equiv \gamma^0 R \psi_0 + \cdots$$

$$R = \frac{3}{2} m^2 + \frac{ie}{2} \gamma_i F^{ij}\gamma_j - \frac{ie}{m} \gamma_0 [D_i, \mathcal{F}_0] - \frac{e^2}{2m^2} \gamma_0 \mathcal{F}_{0i}\gamma_0 \gamma_j \gamma_i \mathcal{F}^{0j}. \quad (36)$$

In terms of the electric and magnetic fields ($E^i = F^{0i}$, $B^i = \bar{F}^{0i}$)

$$\mathcal{F}_{0i} = l_1 E^i + (2l_2 \delta^{ij} + l_5 \epsilon^{ijk} \gamma_0 \gamma_5 \gamma_k) (E_j - i\gamma^5 B_j) \quad (37)$$

the critical matrix $R$ whose loss of invertibility would leave $\psi_0$ (partly) undetermined, is

$$R = -\frac{3}{2} m^2 - e [1 - 2l_2] \gamma_0 \gamma_5 \vec{B} - 2e l_5 \gamma_0 \vec{F}.$$
\[ + \frac{e^2}{2m^2} ([l_1 + 2l_2]^2 \vec{E}^2 + [2l_2]^2 \vec{B}^2) + \frac{e^2}{m^2} [2l_2(l_1 + 2l_2) + 2l_5^2 \gamma_0 \gamma \cdot (\vec{E} \times \vec{B}) + \frac{2e^2}{m^2} l_1 l_5 \gamma^5 \vec{E} \cdot \vec{B} - \frac{ie}{m} [l_1 + 2l_2] \gamma_0 \vec{\nabla} \cdot \vec{E} + \frac{ie}{m} l_5 \gamma^5 \gamma \cdot (\vec{\nabla} \times \vec{E} - i\gamma^5 \vec{\nabla} \times \vec{B}). \] (38)

A pathology in quantisation and causality of the model thus occurs whenever \( \det R = 0 \) as a function of the background fields. To see how this occurs consider first a pure constant electric background. The determinant obviously develops a zero for a critical value of the electric field (with the choice \( l_5 = 0 \))

\[ \vec{E}^2 = 3 \left( \frac{m^2}{e[l_1 + 2l_2]} \right)^2. \] (39)

But the choice of parameters \( l_1 + 2l_2 = 0 \) and \( l_5 \) arbitrary, cannot yield a causal model either, because the determinant vanishes in a pure magnetic background whenever

\[ -\frac{3}{2} m^2 + \frac{e^2}{2m^2} [2l_2]^2 \vec{B}^2 = \pm e [1 - 2l_2] |\vec{B}|. \] (40)

Truncated supergravity (\( l_2 = 1/2, l_5 = 0 \)) and minimal coupling (\( l_1 = l_2 = l_5 = 0 \)) have critical field values \( \vec{B}^2 = 3m^4/e^2 \) and \( \vec{B}^2 = (3m^2/2e)^2 \), respectively (the latter being the well known result of \([3, 4]\)). In the general case \([4]\), has a solution whenever the quadratic

\[ P(\beta) \equiv (2l_2 \beta)^2 \pm 2 (1 - 2l_2) \beta - 3 = 0, \quad \beta \equiv |e\vec{B}|/m^2, \] (41)

has a solution for \( \beta > 0 \). Clearly, for any non-zero value of \( l_2 \), \( P(\beta) \) is positive for large enough \( \beta \) and negative near \( \beta = 0 \) so it always has a zero for some positive \( \beta \): \textit{All} models, minimal or non-minimal, exhibit pathological behaviour\(^5\).

It is interesting to speculate whether further non-minimal couplings may restore causality. In particular, the choice \( l_2 = 1/2, l_5 = 0 \) at least removes the terms linear in \( \vec{B} \) and \( \vec{E} \) in (38) responsible for the original pathology

\(^5\)Precisely the same analysis for a pure electric field yields the same result. Also even an uncharged (real) Majorana field, with only \( l_5 \neq 0 \), displays acausal propagation.
of the minimal model. [In this respect, we note that this choice along with \( l_1 = -2 \) is that of supergravity for which the field-dependent terms of (38) are proportional to the electromagnetic energy density, Poynting vector and charge density and for this reason causality is preserved there, upon taking gravity and the electromagnetic field dynamical.] In Appendix B we generalise (38) to arbitrary non-minimal couplings and show that broad classes of couplings fail to propagate causally.

Finally, as promised, we briefly review the argument linking the appearance of zeroes in \( \det R \) to acausal propagation in the field equations. The computation of [3] amounts to studying the Cauchy problem of (30) and solving for the characteristic surfaces that determine the maximal speed of propagation. This is simply achieved by recalling that characteristics are determined by discontinuities of the highest order derivative terms appearing in the equations of motion [18]. If we denote the discontinuity [..] of the first derivative of the Rarita–Schwinger field across the characteristic as

\[
[\partial_\mu \psi_\nu] = \xi_\mu \Psi_\nu
\]  

where \( \Psi_\nu \) is a non-zero vector-spinor field, then causal propagation forbids timelike \( \xi_\mu \). However from the field equation (30) and its gamma-trace (32) we learn

\[
[R_\mu - \frac{1}{2} \gamma_\mu \gamma R] = \xi_\mu \Psi_\mu - \xi_\mu \gamma \Psi
\]  

(43)

\[
[\gamma R] = 2(\xi_\mu \gamma - \xi \Psi)
\]  

(44)

and in turn

\[
\xi^2 \Psi_\mu = \xi_\mu \xi \Psi .
\]  

(45)

Proceeding by contradiction we take \( \xi_\mu = (1, 0, 0, 0) \) (timelike) without loss of generality since the original (30) is Lorentz covariant. We now need only study the leading discontinuities in time derivatives and in particular

\[
[\dot{\Theta}_2] = \gamma^0 R \Psi_0 = 0.
\]  

(46)

which admits no non-vanishing solution for \( \Psi_0 \) unless \( \det R = 0 \), the condition studied above.

In more physical terms, this is akin to solving the equations of motion in a high energy eikonal limit \( \psi_\mu = \Psi_\mu \exp(itx.\xi) \) with \( t \to \infty \). Clearly, timelike solutions for \( \xi_\mu \) indicate superluminal propagation [4].
5 Discussion

We have seen that the most general charged massive spin 3/2 theory with non-minimal couplings linear in the electromagnetic field strength is described by the two parameter family

\[ \mathcal{L} = -\overline{\psi} \gamma_{\mu \nu \rho} \mathcal{D}^\nu \psi + \frac{ie}{m} \overline{\psi} F_{\mu \nu} \psi + 3 \frac{ie}{4m} (g - 2) \overline{\psi} F_{\mu \nu} \psi - \frac{2iei}{m} \overline{\psi} \gamma_5 \tilde{F}_{\mu \nu} \psi, \] (47)

two of the other a priori admissible parameters being excluded by DOF consistency; the third, corresponding to a diagonal Majorana coupling, did not affect our low energy or causality results. The physical interpretation of the first three terms in (47) was provided by studying LETs. The first is the usual minimally coupled Rarita–Schwinger theory with intrinsic gyromagnetic ratio \( g = 2/3 \). Minimal coupling for half integer systems yields only the spin 1/2 contribution to the Lorentz generators, while the second coupling is the spin 1 Pauli term required for \( g = 2 \). Although \( g = 2 \) is required for low energy unitarity of amplitudes describing pure electromagnetic interactions, more general phenomenological applications deal with the case \( g \neq 2 \), and one may safely include the anomalous magnetic moment coupling given in the third term. [Recall that at low energy, a coupling to \( F_{\mu \nu} \) is equivalent to a coupling to the full Lorentz generators up to a factor 1/3, by virtue of the identity (21).]

The fourth term is more subtle, as it does not contribute at low energy until quadrupole order. It will be an exercise of some physical importance to relate \( l_2 \), as well as effective Lagrangians including gradients of \( F_{\mu \nu} \), to multipole moments along the lines of the method presented here for the magnetic dipole [4]. As we have noted, however, there are already interesting values of \( l_2 \). The first, implying tree unitarity, is \( l_2 = 1/2 \) as well as \( g = 2 \) and is a truncation of \( N = 2 \) supergravity (along the lines of [4], but maintaining the correct DOF). Another possibility is to take \( l_2 = -(g - 2)/8 \) which (see (4)) promotes the anomalous magnetic moment coupling of the third term from one involving only spin 1 to one already including the total Lorentz generators in the Lagrangian.

Our study of causality showed that no model maintaining the correct DOF avoids sharing the pathology of the minimal one. In fact this result applies to
a very broad class of non-minimal couplings (beyond just linear in the field strength); the criteria described in section 4 determine the causality of any non-minimally coupled model. An interesting issue under study is whether including gravity dynamically can improve upon this situation; certainly for supergravities [8] this is the case, although the minimal model in curved space is known to still suffer the usual difficulties [19].

Finally, and perhaps most physically relevant, the models we have studied, despite the formal causal pathologies of the interacting fields, provide a useful parametrization for an effective low energy description of higher spin excitations: They are a field theoretical framework for the generic LET properties.

Acknowledgements

We are indebted to H. Schnitzer and S. Weinberg for reminding us of the Wigner–Eckart theorem’s universality and thank also M. Porrati and P. van Nieuwenhuizen for discussions. This work was supported by the National Science Foundation under grant PHY99-73935 and by the Australian Research Council.

A Appendix: Higher Spin Soft Photon Vertices

The results of section 3.1 are easily generalised to arbitrary higher spin targets. For higher integer spin $s$ we employ a complex symmetric tensor field $\phi_{\mu_1 \cdots \mu_s}$. On-shell, $\phi_{\mu_1 \cdots \mu_s}$ is asymptotic to a free field satisfying

$$\Box - m^2 \phi_{\mu_1 \cdots \mu_s} = 0 = \phi_{\mu \mu_3 \cdots \mu_s} = \partial_\mu \phi_{\mu_2 \cdots \mu_s}. \quad (48)$$

The corresponding half integer spin $s \equiv n + \frac{1}{2}$ representation is a complex Dirac symmetric tensor-spinor $\psi_{\mu_1 \cdots \mu_n}$ obeying free field equations

$$(\not\partial + m) \psi_{\mu_1 \cdots \mu_n} = 0 = \gamma_\mu \psi_{\mu_2 \cdots \mu_n} = \psi_{\mu \mu_3 \cdots \mu_n} = \partial_\mu \psi_{\mu_2 \cdots \mu_n}. \quad (49)$$

Here too it is essential to determine appropriate non-minimal couplings to lower trace and gamma-trace field components to ensure a correct DOF count.
in an electromagnetic background. Although we have not yet studied this
generally, it is tempting to assume that antisymmetry of the non-minimal
interactions is again the correct criterion. In this Appendix however, we
ignore these couplings since they are irrelevant to the soft photon vertex.

The general Lagrangian is the sum of the minimally coupled massive
higher spin action\(^7\) of \([20]\) plus the most general non-minimal couplings (ignoring trace couplings) denoted by \(\mathcal{L}_{\text{NM}}\). For integer spins\(^8\),

\[
\mathcal{L}_{\text{NM}} = -ie l_1 \phi_\mu^* F^{\mu\nu} \phi_\nu
\]

and for half integer spins (the precise analogue of \([2]\)),

\[
\mathcal{L}_{\text{NM}} = -\frac{ie}{m} \left[ l_1 \bar{\psi}_\mu F^{\mu\nu} \psi_\nu + l_2 \bar{\psi} \hat{F} \psi \right]
\]

in the terse notation, appropriate for bilinears, that drops any indices
contracted directly between a field and its complex conjugate (so that, for ex-
ample, \(\bar{\psi} \hat{F} \psi \equiv \bar{\psi}_{\rho_1} \ldots \rho_n \hat{F} \psi^{\rho_1} \ldots \rho_n\)).

The LET for the emission of a single photon for arbitrary spin target is

\[
T_{fi} = \frac{ie}{2s} F_{\mu\nu} M^{\mu\nu} + \mathcal{O}(\omega^2)
\]

where now the Lorentz generators in a higher spin representation are given
by

\[
M_{\mu\nu} = 2ms \varepsilon_\mu^\nu \varepsilon_{[\mu} \varepsilon_{\nu]}
\]

for integer spins, and

\[
M_{\mu\nu} = \frac{1}{2} \bar{u} \gamma_{\mu\nu} u + 2s \bar{u}_{[\mu} u_{\nu]}
\]

for half integer spins, where the initial, \(\varepsilon_{\mu_1} \ldots \varepsilon_{\mu_s}\) and \(u_{\mu_1} \ldots u_{\mu_n}\), respectively, and

\(^7\)Note that in \([20]\) the action is in terms of traceless and gamma-traceless fields symmetric in vector indices along with auxiliary fields corresponding to all possible traces and gamma-traces. Using field redefinitions one may work, equivalently, with unconstrained symmetric fields as above.

\(^8\)Here and throughout, we have ignored derivative couplings, although they may also contribute to the magnetic moment; this is illustrated in \([21]\).
We must now compute the on-shell vertices in the soft photon limit and compare the results with the LET (52). The integer spin case is simple and we find a gyromagnetic ratio

\[ g = \frac{1}{s} - \frac{2l_1}{s} \]  

(55)

where we have included a contribution \( g = 1/s \) from the minimally coupled Lagrangian. (Of course, unlike the half integer case, a second order system is well known to be ambiguous due to possible partial integrations before minimal coupling. In fact the minimal model alone can yield any gyromagnetic ratio between \( g = 0 \) and \( g = 1/s \), the case quoted above being attained by writing the Lagrangian in first order form and only thereafter coupling minimally [21].)

The half integer case directly follows section 3.1: we must include the minimal interaction

\[ \mathcal{L}_{\text{int}}^\text{Min} = -ie \bar{\psi} A \psi \]  

(56)

to which the Gordon identity (18) may be applied unaltered. Once again, there is a special model which requires no further low energy identity identities to fulfill the LET, when \( nl_1 = 4l_2 - 1 \). The LET is satisfied, of course, for all parameters \((l_1, l_2)\) once one derives the obvious generalisation of the identity (21), implying

\[ \mathcal{M}_{\mu\nu} = s \bar{u} \gamma_{\mu\nu} u + \mathcal{O}(\omega) \]  

(57)

As a result one finds

\[ g = \frac{1}{s} - \frac{2(l_1 + 2l_2)}{s} \]  

(58)

which clearly reproduces (22) for \( s = 3/2 \). Note that the higher spin analogue of (7) again implies that an \( i\gamma^5 F_{\mu\nu} \) coupling does not contribute at linear order in \( \omega \), so that low energy physics is encapsulated by a single magnetic moment coupling.

\section*{B Causality of General Non-Minimal Models}

The curious reader may wonder whether there exist causal non-minimal couplings for more general functions \( \mathcal{F}^{\mu\nu} \) of field strengths. The most general
antisymmetric (so that DOFs are maintained) one is \( F_{\mu \nu} = W_{\mu \nu} + i \gamma^5 X_{\mu \nu} + i \gamma^5 \gamma_{\mu \nu} Y + \gamma^5 \gamma_{\mu \nu} Z \) where \( W_{\mu \nu} \) and \( Y \) are parity even, \( X_{\mu \nu} \) and \( Z \) are parity odd, all built from \( F_{\mu \nu}, \tilde{F}_{\mu \nu}, (F_{\rho \sigma} F^{\rho \sigma}), (F_{\rho \sigma} \tilde{F}^{\rho \sigma}) \) and field-gradient dependent terms. [For brevity we omit the diagonal, Majorana, \( l_5 \) term.] Causality is determined by substituting this expansion into the matrix (36) and searching for zeroes in its determinant. If we set \( Z = 0 \) (in any case \( Z \) must be an odd function of the axial scalar \( (F_{\rho \sigma} \tilde{F}^{\rho \sigma}) \), so vanishes for pure electric or pure magnetic field configurations) then the analysis of this determinant is almost identical to that performed above: The third term \( Y \) is a field-dependent mass term so replacing the operator \( D_\mu \rightarrow D_\mu + \frac{1}{2} m^* \gamma_\mu \) where \( m^* = m + Y \), calling \( F^{i0} = E_1^i + i \gamma^5 B_1^i \) (\( E_1^i = W^{i0}, B_1^i = X^{i0} \)) and derivatives of \( m^* \) no longer vanish. The matrix \( R \) of (58) then reads

\[
R = -\frac{3}{2} m^2 + \frac{e^2}{2 m^2} (\tilde{E}_s^2 + \tilde{B}_s^2) + e \gamma_0 \gamma^5 \gamma \cdot (\tilde{B} + \frac{m^*}{m} \tilde{\tilde{B}}_s)
+ \frac{i e}{m} \gamma_0 (\vec{\nabla} \cdot \tilde{E}_s - i \gamma^5 \vec{\nabla} \cdot \tilde{B}_s) + \vec{\gamma} \cdot \vec{\nabla} m^* - \frac{e^2}{m^2} \gamma_0 \gamma \cdot (\tilde{E}_s \times \tilde{B}_s) \quad (59)
\]

For the (simplest) case \( F_{\mu \nu} \) constant, \( \det R \) vanishes whenever

\[
\left[ -\frac{3}{2} m^2 + \frac{e^2}{2 m^2} (\tilde{E}_s^2 + \tilde{B}_s^2) \right] - \left[ e (\tilde{B} + \frac{m^*}{m} \tilde{\tilde{B}}_s) \pm \frac{e^2}{m^2} \tilde{E}_s \times \tilde{B}_s \right]^2 = 0 . \quad (60)
\]

Observe that for \( Y = 0 = Z \), i.e., \( m^* = m \), and with \( F_{\mu \nu} \) growing unboundedly for large \( F_{\mu \nu} \), the model is not causal: For \( F_{\mu \nu} = 0 \) the expression (60) is positive but the first term in square brackets must have a zero for large enough \( \tilde{E}_s \) or \( \tilde{B}_s \) at which point the second term is necessarily negative, and solutions to (60) will exist. While this shows that broad classes of generalised couplings remain acausal, the above completely general criterion can applied to a systematic search for causal models.
