**ABSTRACT:** We recorded predation on the squirrel *Guêlinguetus ingrami* by a Collared Forest-Falcon (*Micrastur semitorquatus*) through camera trapping in a forest fragment of Atlantic Forest in the interior of São Paulo state, Brazil. The squirrel was captured while it moved across the forest floor. A compilation from bibliographic and other sources resulted in 68 vertebrate and 03 invertebrate species as prey of the Collared Forest-Falcon, with birds more commonly reported in the diet of the species. The majority of prey (66% of species) did not exceed 300 g, but some prey species (12%) such as guans (*Penelope* spp.) were heavier than the falcon. The Collared Forest-Falcon could affect the population dynamics of smaller vertebrates in forest fragments of Atlantic Forest due to its flexibility in diet and habitat use, an aspect that deserves a more thorough investigation.

**KEY-WORDS:** bird-mammal, hawk diet, interaction, predator-prey, Seasonal Semideciduous Forest.

The Collared Forest-Falcon (*Micrastur semitorquatus*) is the largest member of the genus composed of seven species of forest falcons, with a total size varying from 46 to 58 cm with average body mass of 563 g for males and 800 g for females (Thorstrom 2000, Ferguson-Lees & Christie 2001, Menq 2016).

The species is found from southern Mexico to central Argentina, including Brazil (Ferguson-Lees & Christie 2001, Thorstrom 2007, Sigrist 2014). Its known habitat includes primary forest, forest edge and secondary forest with dense undergrowth (del Hoyo *et al.* 1993). Individuals nest in cavities of trees and rocks; though there are also records of nests in human buildings (Carrara *et al.* 2007, Vallejos *et al.* 2008, Viana *et al.* 2012). In Guatemala, the home range of Collared Forest-Falcon varied from 996 ha during the reproductive season to 555 ha during the non-reproductive season (Thorstrom 2007).

The Collared Forest-Falcon is a predator that captures its prey on the ground and in vegetation, through ambushes from hidden perches (Sigrist 2014, Menq 2016). It also follows army ant columns, where it captures insectivorous birds (Ferguson-Lees & Christie 2001, Antas 2005). Here we report the predation of the squirrel *Guêlinguetus ingrami*, a predominantly arboreal rodent some 19.6 cm in length and 242 g in body mass (Bonvico *et al.* 2008), which also forages on the ground, by *M. semitorquatus* (Collared Forest-Falcon), and include a summary of the predation events known for this falcon.

Our study area was a forest fragment of 79 ha in the Abraão de Moraes Astronomical Observatory, with a predominance of Atlantic Forest Biome, Semideciduous Seasonal Forest phytophysionomy, in Valinhos city, São Paulo state, southeastern Brazil. This is one of the few forest remnants remaining in the region.

The predation event was recorded through a camera trap (MiniTrapa model - with infrared sensor) installed 30 cm from the ground as part of a survey of medium and large mammals. In addition, we collated the available data on predation events by *M. semitorquatus* from the bibliography and public databases such as Google Images, Wikaves, YouTube and Flickr using as keyword search "Micrastur semitorquatus".
At 09:00 h on 9 October 2016 we recorded a single squirrel *G. ingrami* foraging on the ground on the leaf litter under a closed canopy of an old (45 years) secondary forest (Fig. 1A). The following day, at about the same time and location (23°0′17.48″S; 46°57′48.22″W), we recorded a *M. semitorquatus* attacking a *G. ingrami* on the ground (Fig. 1B). Seconds later, the falcon carried away its prey, probably towards a perch to feed on it. The photographed bird had barred chest plumage, a dark throat and collar and a long and voluminous tail (Fig. 1B), field marks that characterize it as a juvenile of *M. semitorquatus* (Ferguson-Lees & Christie 2001, Menq 2016).

The revision of predation events of *M. semitorquatus* resulted in the identification of 71 predated species (Appendix I) with birds being the most common prey (50 species), followed by mammals (*n* = 11), reptiles (*n* = 6), invertebrates (*n* = 3) and amphibians (*n* = 1). Although most prey species (66%) had a mean body mass less than 300 g (Fig. 2). Prey of *M. semitorquatus* cover a wide size spectrum, with 12% of prey exceeding the mass of the predator itself (Fig. 2).

This note presents the first documented predation record of a *G. ingrami* squirrel by *M. semitorquatus*. Other species of squirrels (*Sciurus depeii* and *S. yuatanensis*) have been reported as prey of this raptor (Throstrom 2000). *Guerlingetus* squirrels are arboreal and inhabit the intermediate and lower strata of the forest descending to the ground to forage (Bonvicino *et al*. 2008), where they are potentially more vulnerable to predators. In the
