Supplemental Material

Childhood Exposure to Ambient Air Pollutants and the Onset of Asthma: An Administrative Cohort Study in Québec

Louis-Francois Tétreault, Marieve Doucet, Philippe Gamache, Michel Fournier, Allan Brand, Tom Kosatsky, and Audrey Smargiassi

Table of Contents

Indirect adjustment for second hand smoke

Table S1. Distributions of estimated annual average concentrations of PM$_{2.5}$ and O$_3$ at both the annual and the birth address in the Montreal sub-cohort

Table S2. Associations between asthma onset and air pollutant levels in Quebec, per increase of an interquartile range in air pollutant levels, without regions of the province where health services may be under-reported

Table S3. Associations between asthma onset and time-varying air pollutant levels, per increase in interquartile range, restricted to non-movers

Table S4. Associations between asthma onset and air pollutant levels, per increase of an interquartile range in air pollutant levels, with reconfirmation of onset when it occurred before the age of five

Table S5. Associations between asthma onset and air pollutant levels, per interquartile range increase in air pollutant levels, stratified by sex

Table S6. Associations between asthma onset and air pollutant levels in Quebec, per increase in interquartile range of pollutant levels, stratified by region
Figure S1. Distribution of the potential bias introduced by second hand smoke on the association between onset of asthma on the island of Montreal and air pollutant levels of: NO$_2$ (for the years 1996 to 2006)  B) PM$_{2.5}$ (for the years 1996 to 2006) and C) O$_3$ at the birth address (for the years 1999 to 2006)

Indirect adjustment for second hand smoke

Individual information on secondhand smoke (SHS) exposure where not available in this study, thus we could not controlled for this potential confounder. However we performed an indirect adjustment for SHS for the Montreal sub-cohort by using a strategy proposed by Steenland and Greenland 2004 and adapted by Villeneuve et al. 2011 for continuous exposures. First, we divided the respective distributions of Montreal NO2, O3 and PM2.5 exposure estimates into quintiles. For these quintiles of exposure, we estimated the proportion of children exposed at home to SHS. Area-specific (i.e. postal code) prevalence of at home childhood exposure to SHS was retrieved from a survey conducted in 2006 in Montreal (Deger et al. 2010). We also retrieved from a meta-analysis (Tinuoye et al. 2013) a rate ratio representing the association between childhood asthma and SHS. The bias associated with SHS for each quintile was then estimated using the following formula for indirect adjustment (Equation 1):

\[ \text{Bias}_q = \frac{I_0 \times ((1 - p_{e,q}) + RR_{e} \times p_{e,q})}{I_0 \times ((1 - p_{e,l}) + RR_{e} \times p_{e,l})} \]

where \( p_{e,q} \) is the prevalence of exposure to SHS at quintile \( q \), \( p_{e,l} \) is the prevalence of exposure to SHS at the lowest quintile and \( RR_{e} \) is the rate ratio of childhood asthma associated with exposure to SHS. \( I_0 \) in this equation is the incidence rate of asthma among children unexposed to SHS. However this equation could be simplified to discard the \( I_0 \) term. As proposed by Villeneuve et al. 2011, we performed a linear regression in order to present estimation of indirectly adjusted point estimates for a continuous scale. In this model, the estimated bias for each quintile (\( \text{Bias}_q \)) was considered as the dependent variable whereas the independent variable was a random sample of a uniform distribution of air pollutant levels per quintile. The slope of this regression represents an estimation of the potential confounding induced by SHS exposure. Finally, the
indirectly adjusted HRs were calculated by dividing the Montreal sub-cohort HRs, adjusted for sex and the Pampalon deprivation index, by the exponentiation of the bias slope. In order to compute the uncertainty around our indirectly adjusted point estimates, we used Monte Carlo sampling with 100,000 replications to repeatedly sample from distributions of rate ratios as well as prevalence exposures to SHS. The distribution the rate ratio linking SHS and childhood asthma was based on data from a meta-analysis (n=20) (Tinuoye et al. 2013), we assumed a normal distribution with a mean value equal to the natural logarithm of the rate ratio and standard deviations equal to the standard errors. Identical assumptions were made to construct the distribution around our association between childhood asthma and outdoor air pollutants that were derived from this study. The distribution of the prevalence exposure to SHS was assessed using data from the aforementioned survey (Deger et al. 2010). We presumed a normal distribution with a mean equal to the logit of the proportion of exposed. Adjusted HRs and their 95% Monte Carlo confidence interval were calculated for each pollutant.
Table S1. Distributions of estimated annual average concentrations of PM$_{2.5}$ and O$_3$ at both the annual and the birth address in the Montreal sub-cohort

|                | Birth address |             | Time-varying |            |
|----------------|---------------|-------------|--------------|------------|
|                | O$_3^b$       | PM$_{2.5}^c$| O$_3^b$      | PM$_{2.5}^c$|
| minimum        | 12.19         | 10.10       | 12.19        | 9.73       |
| 25%            | 30.11         | 13.42       | 29.69        | 13.00      |
| 50%            | 31.27         | 13.94       | 31.27        | 13.94      |
| 75%            | 32.88         | 14.40       | 32.88        | 14.40      |
| Maximum        | 38.06         | 14.85       | 38.08        | 14.59      |
| Interquartile range | 3.09 | 0.99 | 3.18 | 1.41 |
| Mean           | 31.55         | 13.65       | 31.16        | 13.62      |

$^a$exposures was based on annual level
$^b$for the years 1999-2010 (in ppb)
$^c$for the years 1996-2011 (in µg/m$^3$)
NO$_2$ levels in the Montreal sub-cohort are presented in table 2 of the article.
Table S2. Associations between asthma onset and air pollutant levels in Quebec, per increase of an interquartile range in air pollutant levels, without regions of the province where health services may be under-reported\textsuperscript{a,b,c}

| Pollutant | Sample size | Interquartile range | Hazard ratios (95% CI) | Interquartile range | Hazard ratios (95% CI) |
|-----------|-------------|---------------------|------------------------|---------------------|------------------------|
| O\textsubscript{3} | 780,593     | 3.22 ppb            | 1.11 (1.10, 1.12)\textsuperscript{‡} | 3.26 ppb            | 1.13 (1.12, 1.13)\textsuperscript{‡} |
| PM\textsubscript{2.5} | 1,045,653   | 6.50 µg/m\textsuperscript{3} | 1.31 (1.28, 1.33)\textsuperscript{‡} | 6.53 µg/m\textsuperscript{3} | 1.31 (1.29, 1.33)\textsuperscript{‡} |

\textsuperscript{a}associations adjusted for sex and indexes of social and material deprivation
\textsuperscript{b}The province of Quebec without the following social and healthcare regions: North of Quebec, Outaouais, the North Shore, the Gaspésie and the Magdalene
