MATRIX PROBLEMS, TRIANGULATED CATEGORIES AND STABLE HOMOTOPY TYPES

YURIY A. DROZD

ABSTRACT. We show how the matrix problems can be used in studying triangulated categories. Then we apply the general technique to the classification of stable homotopy types of polyhedra, find out the “representation types” of such problems and give a description of stable homotopy types in finite and tame cases.

The technique of matrix problems, especially, of bimodule categories, has proved their efficiency in lots of problems from representation theory, algebraic geometry, group theory and other domains of modern algebra. During last years, mainly due to the works of Baues, Henn, Hennes, and the author, it has found new applications in algebraic topology, namely, in studying stable homotopy classes of polyhedra (see [19], [8], [4]–[7], [16]). In the survey [15] the author has picked out the background of this approach, which is based on the triangulated structure of the stable homotopy category. In this paper we show that the same method can be used in general situation, when we construct subcategories of a triangulated category from simpler ones (see Section 1). Then we summarize what can be done using this technique for
the classification problem of stable homotopy classes. Namely, we consider the subcategories $\mathcal{F}_n$ of the stable homotopy category consisting of polyhedra having only cells of $n$ consecutive dimensions. We classify polyhedra from $\mathcal{F}_n$ for $n \leq 4$ and show that for $n > 4$ this problem becomes wild in the sense of the representation theory of algebras. Then we consider the subcategories $\mathcal{T}_n$ of $\mathcal{F}_n$ consisting of polyhedra with no torsion in one integral homologies. This time we classify polyhedra from $\mathcal{T}_n$ for $n \leq 7$ and show that for $n > 7$ their classification is also a wild problem. In some sense, these results are “final,” though we are sure that this technique will be useful for some other problems of algebraic topology as well as for studying other triangulated categories.

Since the technical details of calculations are sometimes rather cumbersome and can be found in the previous papers, we usually omit them, just outlining the ideas.

1. Matrix problems arising in triangulated categories

Let $C$ be a triangulated category with the shift $A \mapsto SA$, $\mathcal{A}$ and $\mathcal{B}$ be two fully additive (but usually not triangulated) subcategories of $C$. We denote by $\mathcal{A} \uparrow \mathcal{B}$ the full subcategory of $C$ consisting of all objects $C$ arising in triangles

$$\begin{array}{c}
A \overset{a}{\rightarrow} B \overset{b}{\rightarrow} C \overset{c}{\rightarrow} SA \\
\downarrow \alpha \downarrow \beta \downarrow \gamma \downarrow \downarrow \downarrow \downarrow S\alpha \downarrow \downarrow \downarrow S\beta
\end{array}$$

We also denote by $\mathcal{I}$ the ideal of the category $C$ consisting of all morphisms $\gamma : C \rightarrow C'$ that factorizes both through $\mathcal{B}$ and through $S\mathcal{A}$, i.e. such that $\gamma = \gamma' \alpha = \gamma'' \beta$, where $\alpha : C \rightarrow SA$, $\beta : C \rightarrow B$, where $A \in \mathcal{A}$, $B \in \mathcal{B}$.

On the other hand, we consider the $\mathcal{A}$-$\mathcal{B}$-bimodule $\mathcal{C}(a, b)$, which is the restriction of the regular $C$-bimodule $C(A, B)$ for $A \in \mathcal{A}, B \in \mathcal{B}$. We often omit subscripts and denote this bimodule by $C$ if it cannot lead to misunderstanding. Recall that the bimodule category $\text{Bim}(\mathcal{C}(a, b))$ has $\bigcup_{A \in \mathcal{A}} \mathcal{C}(A, B)$ as the set of objects, while the set of morphisms $\text{Bim}(a, a')$, where $a : A \rightarrow B$, $a' : A' \rightarrow B'$, is defined as

$$\{ (\alpha, \beta) \mid \alpha : A \rightarrow A', \beta : B \rightarrow B', \beta a = a' \alpha \}.$$ 

We denote by $\mathcal{I}$ the ideal of $\text{Bim}(\mathcal{C}(a, b))$ consisting of all morphisms $(\alpha, \beta) : a \rightarrow a'$ such that $\alpha$ factors through $a$ and $\beta$ factors through $a'$.

We define a functor $F : \text{Bim}(\mathcal{C}(a, b)) \rightarrow (\mathcal{A} \uparrow \mathcal{B})/\mathcal{I}$ as follows. For every morphism $a : A \rightarrow B$, choose a triangle like (1.1) and set $C = Fa$. If $a' : A' \rightarrow B'$, $C' = Fa'$ and $(\alpha, \beta) \in \text{Bim}(a, a')$, there is $\gamma : C \rightarrow C'$ such that the diagram

$$\begin{array}{c}
A \overset{a}{\rightarrow} B \overset{b}{\rightarrow} C \overset{c}{\rightarrow} SA \overset{Sa}{\rightarrow} SB \\
\downarrow a \downarrow \beta \downarrow \gamma \downarrow \downarrow \downarrow \downarrow S\alpha \downarrow \downarrow \downarrow \downarrow S\beta
\end{array}$$
commutes. Set $F(\alpha, \beta) = \gamma \mod \mathcal{I}$. We must check that the latter definition is consistent. Indeed, if $\gamma' : C \to C''$ is another morphism making diagram (1.2) commutative, $g = \gamma - \gamma'$, then $gb = c'g = 0$, therefore there are $f : SA \to C'$ and $h : C \to B'$ such that $g = cf = bh$, i.e. $g \in \mathcal{I}$. Thus $F$ is well-defined.

Suppose now that $\mathcal{C}(B, SA) = 0$ for all $A \in \mathcal{A}$, $B \in \mathcal{B}$. In this situation we define a functor $G : \mathcal{A} \uparrow \mathcal{B} \to \text{Bim}(\mathcal{A})/\mathcal{I}$ as follows. Let $C \in \mathcal{A} \uparrow \mathcal{B}$. Choose one of such triangles Since

\[ A' \xrightarrow{a'} B' \xrightarrow{b} C' \xrightarrow{c'} SA' \quad \text{with} \quad A' \in \mathcal{A}, \ B' \in \mathcal{B}, \]

and $\gamma : C \to C''$, then $c'\gamma b = 0$, hence $\gamma b = b'\beta$ for some $\beta : B \to B'$. Choose one of such triangles Since

\[ B \xrightarrow{b} C \xleftarrow{\alpha} SA \xrightarrow{Sa} SB \]

and

\[ B' \xrightarrow{b'} C' \xleftarrow{c'} SA' \xrightarrow{Sa'} SB' \]

are also triangles, there is a morphism $\alpha : A \to A'$ that makes the diagram (1.2) commutative, thus $(\alpha, \beta) \in \text{Bim}(a, a')$. Set $G\gamma = (\alpha, \beta)$ mod $\mathcal{I}$. If $(\alpha', \beta')$ is another pair making (1.2) commutative, then $(\beta - \beta')b' = 0$, hence $\beta - \beta' = a'f$ for some $f : B \to A'$; in the same way $S\alpha - S\alpha' = g(Sa)$, i.e. $\alpha - \alpha' = g'a$ for some $g : SB \to SA'$ and $g' : B \to A'$ such that $Sg' = g$. Therefore $(\alpha - \alpha', \beta - \beta') \in \mathcal{I}$, so the functor $G$ is well-defined.

**Theorem 1.1.** Suppose that $\mathcal{C}(B, SA) = 0$ for all $A \in \mathcal{A}$, $B \in \mathcal{B}$. Then the functors $F, G$ constructed above induce quasi-inverse functors $\bar{F} : \text{Bim}(\mathcal{A})/\mathcal{I} \to (\mathcal{A} \uparrow \mathcal{B})/\mathcal{I}$ and $\bar{G} : (\mathcal{A} \uparrow \mathcal{B})/\mathcal{I} \to \text{Bim}(\mathcal{A})/\mathcal{I}$. Thus $(\mathcal{A} \uparrow \mathcal{B})/\mathcal{I} \to \text{Bim}(\mathcal{A})/\mathcal{I}$. Moreover, $\mathcal{I}^2 = 0$, therefore, the natural functor $\Pi : (\mathcal{A} \uparrow \mathcal{B}) \to (\mathcal{A} \uparrow \mathcal{B})/\mathcal{I}$ is an epivalence.

Recall that an *epivalence* is a functor $E : \mathcal{C}_1 \to \mathcal{C}_2$, which is

- **full**, i.e. all induced maps $\mathcal{C}_1(X, Y) \to \mathcal{C}_2(EX, EY)$ are surjective;
- **dense**, i.e. every object from $\mathcal{C}_2$ is isomorphic to $EX$ for some $X \in \mathcal{C}_1$;
- **conservative**, i.e. $f \in \mathcal{C}_1(X, Y)$ is invertible if and only if so is $Ef \in \mathcal{C}_2(EX, EY)$.

(In [2] such functors are called *detecting*.) Note that then also

- $X \simeq Y$ in $\mathcal{C}_1$ if and only if $EX \simeq EY$ in $\mathcal{C}_2$;
- if $\mathcal{C}_1$ and $\mathcal{C}_2$ are additive, then an object $X \in \mathcal{C}_1$ is indecomposable (into a nontrivial direct sum) if and only if so is $EX$.

**Proof.** One immediately sees that $F(\mathcal{I}) = 0$ and $G(\mathcal{I}) = 0$, hence $F$ and $G$ are well-defined. Moreover, we have already seen that, given
(α, β), the morphism γ is defined up to a summand from I, and given γ, the pair (α, β) is defined up to a summand from I. It obviously implies that FG ≃ Id_nlimits and GF ≃ Id_nlimits. If γ : C → C' and γ' : C' → C'' are from I, then γ = g* for some f : C → B and g : B → C', where B ∈ B, while γ' = g'* for some f' : C' → SA and g' : A → C'', where A ∈ A. Then γ/γ = g'/g* = 0, since f'g ∈ C(B, SA). Thus I^2 = 0 and, therefore, I is an equivalence. □

**Corollary 1.2.** Under conditions of Theorem [1.1] let V be a subbimodule of A such that f1af2 = 0 whenever a ∈ V, f1 ∈ C(Bi, Ai) with Ai ∈ A, Bi ∈ B (i = 1, 2). Denote by A ⊨ B the full subcategory of A ⊨ B consisting of all objects C arising in triangles [1.1] with a ∈ V, I = I ∩ (A ⊨ B), J = J ∩ Bim(V). Then the functor F and G constructed above induce quasi-inverse functors F : Bim(V)/I → (A ⊨ B)/I and G : (A ⊨ B)/I → Bim(V)/J. Thus (A ⊨ B)/I ∼ Bim(V)/J. Moreover, I^2 = 0 and J^2 = 0, therefore, the natural functors (A ⊨ B)/I → (A ⊨ B)/I and Bim(V) → Bim(V)/J^2 are equivalences. In particular, there is a one-to-one correspondences between isomorphism classes of objects and of indecomposable objects from A ⊨ B and Bim(V).

## 2. Stable homotopy category

In this paper the word “polyhedron” is used as a synonym for “finite cell (or CW) complex”. We denote by Hot the category of punctured topological spaces with homotopy classes of continuous maps as morphisms and by CW its full subcategory consisting of polyhedra. We denote by CX the cone over the space X, i.e. the factor space X × I/X × 1, I = [0, 1] being the unit interval. For a map f : X → Y we denote by Cf the cone of this map, i.e. the factor space (Y ∪ CX)/~ where the equivalence relation ~ is given by the rule f(x) ~ (x, 0). Let also SX be the suspension of X, i.e. the factor space CX/(X × 0). This operation induces a functor S : Hot → Hot. Note that for every X the space SX is an H-cogroup and the n-fold suspension S^nX is a commutative H-cogroup for n ≥ 2 [23 2.21–2.26]. Therefore, Hot(S^nX, Y) is a group, commutative for n ≥ 2. The natural maps Hot(S^nX, S^nY) → Hot(S^{n+1}X, S^{n+1}Y) are group homomorphisms. Set

\[ \text{Hos}(X, Y) = \lim_{n \to \infty} \text{Hot}(S^nX, S^nY). \]

It is a group called the group of stable maps from X to Y. Thus we get the stable homotopy category Hos and its full subcategory I consisting of polyhedra. We also denote by CF and I respectively the full subcategories of CW and of I consisting of torsion free polyhedra X, i.e. such that all integral homology groups H_k(X) = H_k(X, Z) are
torsion free. The groups $\text{Hos}(S^n, X)$ are called the \textit{stable homotopy groups} of the space $X$ and denoted by $\pi^n_S(X)$.

The category $\text{Hos}$ is additive, with the \textit{bouquet} (or \textit{wedge}) $X \vee Y$ playing the role of direct sum. Moreover, $\text{Hos}$ is \textit{fully additive}, i.e. every idempotent in it splits \cite{12} Theorem 4.8. The suspension induces a functor, which we also denote by $S : \text{Hos} \to \text{Hos}$. Obviously, it is fully faithful. Thus we can “supplement” it so that $S$ becomes an equivalence. To do it, we consider formal “imaginary spaces” $S^n X$ with $n < 0$ setting, for $n < 0$ or $m < 0$, $\text{Hos}(S^n X, S^m Y) = \text{Hos}(S^{n+k} X, S^{m+k} Y)$, where $k = \min(n, m)$. Then we consider formal bouquets $\bigvee_{i=1}^s X_i$, where each $X_i$ is either a “real” or an “imaginary” space, and define $\text{Hos}(\bigvee_{j=1}^r Y_j, \bigvee_{i=1}^s X_i)$ as the set of $r \times s$ matrices $(f_{ij})$ with $f_{ij} \in \text{Hos}(Y_j, X_i)$ (see \cite{12} for details). As a result we get the category (also denoted by $\text{Hos}$), where $S$ is an auto-equivalence.

In fact, the new category is a \textit{triangulated} category. The triangles in it are the \textit{cofibration sequences}, i.e. those isomorphic to the \textit{cone sequences}

$$ X \xrightarrow{f} Y \xrightarrow{g} Cf \xrightarrow{h} SX $$

where $g$ is the natural embedding $Y \to Cf$ and $h$ is the natural surjection $Cf \to SX \simeq Cf / Y$ \cite{22}. Note that in the stable category $\text{Hos}$ they coincide with the \textit{fibration sequences} \cite{12}, though we do not use this fact.

We denote by $\text{CW}_n^k$ the full subcategory of $\text{CW}$ consisting of $(n-1)$-connected cell complexes of dimension at most $n+k$. If $X \in \text{CW}_n^k$, one can suppose that its $(n-1)$-th skeleton $X^{n-1}$ (the “$(n-1)$-dimensional part” of $X$) consist of a unique point and $X$ has no cells of dimensions greater than $n+k$. Following Baues, we describe such a cell complex using its \textit{gluing} (or \textit{attachment}) \textit{diagram}, which looks like (for $n = 7, k = 6$)

In this diagram each bullet on the level $m$ corresponds to an $m$-dimensional cell, i.e. to a ball $B^m$ glued to the $(m-1)$-dimensional skeleton $X^{m-1}$ by a map of its boundary $f : S^{m-1} \to X^{m-1}$. The lines between this bullet and the lower ones describe the nonzero components of the map $f$. If there are more than one nonzero map between $S^{m-1}$ and a smaller
$S^l$ ($l < m$), these lines carry some marks precising the corresponding maps. Especially, in our example the groups $\text{Hos}(S^{l+3}, S^l)$ are cyclic of order 24, so we put the marks that show, which multiple of the generator is used for this gluing. There are no marks on other lines, since the groups $\text{Hos}(S^{l+2}, S^l)$ are of order 2, so only have one nonzero element.

Every polyhedron from $\mathcal{I}$ decomposes into a direct sum of indecomposable ones. Note that such a decomposition is far from being unique (see [12, 4.2] for examples). Nevertheless, a description of indecomposable polyhedra in $\mathcal{I}$ can be a good first step towards the classification problem. Moreover, if the endomorphism ring $E_0(X) = \text{Hos}(Y, Y)$ is \textit{local} and $Y \vee Y' \cong \bigoplus_i Y_i$, there is an index $i$ such that $Y_i \cong Y \vee Y''$ [11, Lemma I.3.5] Hence, in all decompositions of a polyhedron $X$ into bouquets of indecomposables the multiplicity of $Y$ is the same.

Another approach gives the notion of \textit{congruence}. Namely, we say that two polyhedra $X, Y$ are \textit{congruent} if there is a polyhedron $Z$ such that $X \vee Z \cong Y \vee Z$. One can show, following [21] or [13], that an equivalent condition is that the images of $X$ and $Y$ in all localizations $\mathcal{I}_p$ of the stable homotopy category are isomorphic. Here $\mathcal{I}_p$ ($p$ is a prime integer) is the category whose objects are polyhedra, but $\text{Hos}_p(X, Y) = \text{Hos}(X, Y)$ $\odot \mathbb{Z}_p$, where $\mathbb{Z}_p$ is the ring of $p$-adic integers. (The same notion is obtained if we replace $\mathbb{Z}_p$ by the subring $\{a/b \mid a, b \in \mathbb{Z}, p \nmid b\}$ of the rational numbers.) We call the classes of congruence \textit{genera}, like they do in the theory of integral representations. Though genera satisfy the cancellation property (in fact, by definition), their decomposition into bouquets of indecomposables is not unique too (see the first of the cited examples from [12]).

Recall that due to the Generalized Freudenthal Theorem [12, Theorem 1.21] there is no need to go up to infinity in defining $\text{Hos}(X, Y)$ if we deal with polyhedra. Namely, if $Y$ is $(n-1)$-connected and $\dim X \leq m$, then the map $\text{Hot}(X, Y) \to \text{Hot}(SX, SY)$ is bijective if $m < 2n-1$ and surjective if $m = 2n-1$. It implies that the map $\text{Hot}(S^kX, S^kY) \to \text{Hos}(X, Y)$ is bijective for $k > m - 2n + 1$ and surjective for $k = m - 2n + 1$. In particular, if $Y$ is $(n-1)$-connected, $\pi^S_m(Y) \cong \pi_{2(m-n+1)}(S^{m-n+2}Y)$. Moreover, on the subcategory of $\text{Hot}$ consisting of simply connected spaces the suspension functor is conservative. Therefore, the induced functor $\text{CW}^k_n \to \text{CW}^k_{n+1}$ is an equivalence for $n > k + 1$ and an equivalence for $n = k + 1$. Denote by $\mathcal{I}_n$ the image in $\mathcal{I}$ of the category $\text{CW}^{n-1}_n$. The polyhedra from $\mathcal{I}_n$ can only have cells on $n$ consecutive levels (from $n$-th up to $(2n-1)$-th) and every polyhedra having cells on $n$ consecutive levels is isomorphic in $\mathcal{I}$ to $S^m X$ for some integer $m$ and some $X \in \mathcal{I}_n$. We also denote by $\mathcal{I}_n$ the full subcategory of $\mathcal{I}_n$ consisting of torsion free polyhedra.

\textbf{Definition 2.1} (cf. [3]). An \textit{atom} is an indecomposable object $A$ from $\mathcal{I}_n$, which does not belong to $S(\mathcal{I}_{n-1}) \cup S^2(\mathcal{I}_{n-1})$. (In other words, any polyhedron isomorphic to $A$ in $\mathcal{I}$ must have cells of dimensions $n$
and 2n − 1.) If A is an atom, all polyhedra of the sort $S^mA$ are called suspended atoms.

This definition immediately implies that every polyhedron is isomorphic in $\mathcal{S}$ to a bouquet of suspended atoms, though, as we have mentioned, such a decomposition is not unique. Note that, unlike Baues, we consider $S^1$ as an atom (a unique atom in $\mathcal{S}_1$), hence all spheres are considered as suspended atoms. Note also that this definition implies that all atoms are of odd dimensions: an atom from $\mathcal{S}^n$ is of dimension $\dim 2^n − 1$.

To clarify the structure of $\mathcal{S}^n$ we use the technique from Section 1. Namely, choose an integer $m$ such that $0 \leq m < n − 1$ and set

\begin{align*}
\mathcal{A} &= \mathcal{A}_{n,m} = S^{2m+1} \mathcal{S}_{n-m-1}, \\
\mathcal{B} &= \mathcal{B}_{n,m} = S^{m-1} \mathcal{S}_{m+1}, \\
\mathcal{I}_{n,m} &= S_{n,m} \mathcal{A}_{n,m}, \\
\mathcal{J}_{n,m} &= \{ f : X \to Y \mid X, Y \in \mathcal{S}_n, f \text{ factors both through } \mathcal{B} \text{ and through } S\mathcal{A} \}, \\
\mathcal{J}_{n,m} &= \{ (\alpha, \beta) \in \text{Bim}(a, a') \mid a, a' \in \mathcal{S}_{n,m}, \\
&\alpha \text{ factors through } a \text{ and } \beta \text{ factors through } a' \}.
\end{align*}

Then polyhedra from $\mathcal{A}$ only have cells in dimensions from $n + m$ up to $n − m − 2$, while those from $\mathcal{B}$ only have cell in dimensions from $n$ up to $n + m$. If $C \in \mathcal{I}_n$, its $(n + m)$-th skeleton $B$ belongs to $\mathcal{B}$, while the factor space $C/B$ belongs to $S\mathcal{A}$, i.e. $C/B \simeq SA$, $A \in \mathcal{A}$. Then $C \in \mathcal{A} \uparrow \mathcal{B}$, since $A \to B \to C \to C/B \simeq A$ is a cofibration sequence.

On the other hand, any object from $\mathcal{A} \uparrow \mathcal{B}$ obviously belongs to $\mathcal{I}_n$. So we have proved

**Theorem 2.2.** $\mathcal{I}_n \simeq \mathcal{A}_{n,m} \uparrow \mathcal{B}_{n,m}$. Thus $\mathcal{I}_n/\mathcal{I}_{n,m} \simeq \text{Bim}(\mathcal{S}_{n,m})/\mathcal{J}_{n,m}$. Moreover, $\mathcal{J}_{n,m}^2 = 0$.

To consider torsion free polyhedra, we set

\begin{align*}
\mathcal{A}^0 &= \mathcal{A}_{n,m}^0 = S^{2m+1} \mathcal{S}_{n-m-1}, \\
\mathcal{B}^0 &= \mathcal{B}_{n,m}^0 = S^{m-1} \mathcal{S}_{m+1}, \\
\mathcal{J}_{n,m}^0 &= \mathcal{J}_{n,m} \cap \mathcal{A}_{n,m}^0, \\
\mathcal{J}_{n,m}^0 &= \mathcal{J}_{n,m} \cap \text{Bim}(\mathcal{J}_{n,m}^0).
\end{align*}

To get an analogue of Theorem 2.2 we need the following lemma.

**Lemma 2.3.** Let $f \in \text{Hos}(A, B)$, where $A$ and $B$ are torsion free polyhedra, $A$ is $(m − 1)$-connected, $\dim B \leq m$ and $Cf$ is also torsion free. There are decompositions $A \simeq C \oplus A'$, $B \simeq C \oplus B'$ such that, with
respect to this decomposition, \( f = \begin{pmatrix} \text{Id} & 0 \\ 0 & g \end{pmatrix} \) with \( H_m(g) = 0 \) and \( Cf \simeq Cg \).

**Proof.** Note first that if \( A = kS^m, B = lS^m \) are bouquets of \( m \)-dimensional spheres, then \( H_m(A) = m\mathbb{Z}, H_m(B) = l\mathbb{Z}, \) and the natural map \( \text{Hom}(A, B) \to \text{Hom} \) is an isomorphism. In particular, every decomposition of \( H_m(A) \) arises from a decomposition of \( A \), and the same is true for \( B \). In this case \( H_m(f), \) or, the same, \( f \) is actually an integer matrix and there are decompositions \( A \simeq C \oplus A', B \simeq C \oplus B' \) (all summands are, of course, also bouquets of spheres) such that, with respect to them, \( f = \begin{pmatrix} \text{Id} & 0 \\ 0 & d \end{pmatrix} \),

where \( d : A' \to B' \) can be presented by diagonal matrix without unit components.

In general case, the calculation of homologies of cell spaces from Chapter 10 shows that the embedding \( \alpha : A^m \to A \) induces a surjection \( H_m(A^m) \to H_m(A) \), while the surjection \( \beta : B \to B = B/B^{-1} \) induces an embedding \( H_m(B) \to H_m(B) \) with torsion free cokernel. Therefore, there are decompositions \( A^m \simeq A_1 \oplus A_0, B \simeq B_1 \oplus B_0 \) such that the restriction of \( H_m(\alpha) \) onto \( A_1 \) is an isomorphism, and that onto \( A_0 \) is 0, while \( H_m(f) \) induces an isomorphism \( H_m(B) \to \text{im} \), \( H_m(B_1) \). Denote by \( \alpha_1 : A_1 \to A \) and \( \beta_1 : B \to B_1 \) the corresponding components of \( \alpha \) and \( \beta \). As above, there are decompositions \( A_1 \simeq C \oplus A_0, B_1 \simeq C \oplus B_0 \) such that, with respect to them, the morphism \( \beta_1 f \alpha_1 = \begin{pmatrix} \text{Id} & 0 \\ 0 & d \end{pmatrix} \), where \( d \) can be presented by diagonal matrix without unit components. Denote by \( \iota : C \to A_1 \) the natural embedding (presented by the matrix \( \begin{pmatrix} \text{Id} & 0 \\ 0 & d \end{pmatrix} \)) and by \( \pi : B_1 \to C \) the natural projection (presented by the matrix \( \begin{pmatrix} \text{Id} & 0 \\ 0 & d \end{pmatrix} \)). Then \( \pi \beta_1 f \alpha_1 \iota = \text{Id} \), \( \beta_0 g \alpha_0 \), where \( \alpha_0 : A_0 \to A' \) and \( \beta_0 : B' \to B_0 \). Note that \( \alpha_0 \) and \( \beta_0 \) also induce isomorphisms of the \( m \)-th homology groups, so \( \text{Coker} \simeq \text{Coker} \). Since this cokernel embeds in \( H_m(Cg) \), it is torsion free. Therefore, \( d = 0 \), whence \( H_m(g) = 0 \).}

**Theorem 2.4.** \( \mathcal{T}_n \simeq \mathcal{A}_{n,m}^{0,0} \). Thus \( \mathcal{T}_n/\mathcal{A}_{n,m}^{0,0} \simeq \text{Bim}(\mathcal{A}_{n,m}^{0,0})/\mathcal{A}_{n,m}^{0,0} \). Moreover, \( (\mathcal{A}_{n,m}^{0,0})^2 = (\mathcal{J}_{n,m}^{0,0})^2 = 0 \), so this equivalence induces one-to-one correspondences between isomorphism classes of objects and of indecomposable objects in \( \mathcal{T}_n \) and in \( \text{Bim}(\mathcal{A}_{n,m}^{0,0}) \).
Proof. Let $C \in \mathcal{T}_n$, $B = C^{n+m}$, $SA \simeq C/B$. The triangle
\[ A \xrightarrow{a} B \xrightarrow{b} C \xrightarrow{c} SA \]
gives rise to the exact sequence of homologies
\[ \cdots \rightarrow H_k(A) \xrightarrow{H_k(a)} H_k(B) \xrightarrow{H_k(b)} H_k(C) \xrightarrow{H_k(c)} H_k(SA) \simeq \]
\[ \simeq H_{k-1}(A) \xrightarrow{H_{k-1}(a)} H_{k-1}(B) \xrightarrow{H_{k-1}(b)} H_{k-1}(C) \rightarrow \cdots \]
If $k < n+m$, then $H_k(A) = H_{k-1}(A) = 0$, so $H_k(B) \simeq H_k(C)$ is torsion free. If $k > n+m$, we get in the same way that $H_k(A) \simeq H_{k+1}(C)$ is also torsion free. Let now $k = n+m$, then we get the exact sequence
\[ 0 \rightarrow H_{n+m+1}(C) \rightarrow H_{n+m}(A) \xrightarrow{H_{n+m}(a)} H_{n+m}(B) \rightarrow H_{n+m}(C) \rightarrow 0. \]
Note that $H_{n+m}(B)$ is always torsion free, since $B$ contains no cells of dimensions bigger than $n+m$, hence $B \in \mathcal{T}$. Therefore, $H_{n+m}(A)$ is torsion free too, so $A \in \mathcal{T}$. Moreover, Coker $\text{nolimits} H_{n+m}(a)$ is also torsion free. As both $H_{n+m}(A)$ and $H_{n+m}(B)$ are free, it means that $H_{n+m}(A) \simeq M \oplus M'$, $H_{n+m}(B) \simeq M \oplus M''$ so that $H_{n+m}(a)$ induces isomorphism $M \rightarrow M$ and is zero on $M'$. By Lemma 2.3, there are decompositions $A \simeq A_0 \vee A'$, $B \simeq A_0 \vee B'$ such that, with respect to them, $a = \begin{pmatrix} \text{Id} & 0 \\ 0 & a' \end{pmatrix}$, where $a' \in \mathcal{A}^0$. Then $Ca' \simeq Ca \simeq C$, so $C \in \mathcal{A}^0 \uparrow_{\mathcal{A}^0} \mathcal{B}^0$. On the other hand, if $C \in \mathcal{A}^0 \uparrow_{\mathcal{A}^0} \mathcal{B}^0$, i.e. belongs to a triangle (2.4) with $A \in \mathcal{A}^0$, $B \in \mathcal{B}^0$ and $H_{n+m}(a) = 0$, the exact sequence of homologies implies that $C \in \mathcal{T}_n$.

To prove the remaining assertions, it is enough to show that $uav = 0$ for every $a \in \mathcal{A}^0(A,B)$, $v : B' \rightarrow A$, $u : B \rightarrow A'$, where $A, A' \in \mathcal{A}^0$, $B, B' \in \mathcal{B}^0$ (see Corollary 1.2). Since $H_{n+m}(a) = 0$, the induced map $A^{m+n} \rightarrow B/B^{m+n-1}$ is zero. On the other hand, $\mathcal{A}(B', A/A^{m+n}) = 0 = \mathcal{A}(B')^{m+n-1}, A^{m+n}$, so the map $v : B' \rightarrow A$ factors through a map $B'/B^{m+n-1} \rightarrow A^{m+n}$. Since the same holds for $u$, it implies that $uav = 0$. \hfill $\Box$

We shall also use the following obvious lemma.

**Lemma 2.5.** Let $X \in \mathcal{N}_n$, $H_i = H_i(X)$. If $X$ is decomposable, there are decompositions $H_i = H'_i \oplus H''_i$ and indices $j, k$ such that both $H'_j \neq 0$ and $H''_k \neq 0$.

(Note also that $H_i(X) = 0$ for $i < n$ or $i > 2n - 1$.)

3. **Discrete case: Whitehead–Chang Theorem**

We apply now Theorem 2.2 to polyhedra from $\mathcal{N}_n$ for small $n$. First, we recall some values of stable homotopy groups [20, Sections XI.15–16]:

- $\pi^{S}_n(S^n) \simeq \mathbb{Z}/2$, the generator being the (suspended) Hopf map $\eta = 2^{n-1}h_2$, where $h_2$ is the Hopf fibration $S^3 \rightarrow S^2$;
• $\pi_{n+2}^S(S^n) \simeq \mathbb{Z}/2$, the generator being the double Hopf map $\eta^2$,
i.e. the composition of Hopf maps $S^{n+2} \to S^{n+1} \to S^n$;
• $\pi_{n+3}^S(S^n) \simeq \mathbb{Z}/24$, the generator being $\nu = S^{n-4}h_4$, where $h_4$
is the Hopf fibration $S^7 \to S^4$. Moreover, the composition $\eta^3 : S^{n+3} \to S^{n+2} \to S^{n+1} \to S^n$
equals $12\nu$.

If $n = 1$, the only atom in $\mathcal{F}_1$ is $S^1$, and every polyhedron is a
bouquet of several copies of $S^1$. If $n = 2$, $\mathcal{F}_2 = \mathcal{F}_2.0 \uparrow \mathcal{B}_2.0$, and
$\mathcal{F}_2.0 = \mathcal{B}_2.0 = S\mathcal{F}_1$. Thus every polyhedron $C$ from $\mathcal{F}_2$ is isomorphic to
the cone of a map $a : kS^2 \to lS^2$. Since Hos$(S^2, S^2) = \mathbb{Z}$, the map $a$
can be considered as a matrix $(a_{ij}) \in \text{Mat}(l \times k, \mathbb{Z})$. If $a'$ is another
object from $\mathcal{F}_{2.1}$, also considered as a matrix from Mat\n(\text{nolimits})\text{Mat}(l' \times k', \mathbb{Z})$, a morphism $a \to a'$ in Bim($\mathcal{F}_{2.1}$) is given by a pair of matrices
$\alpha \in \text{Mat}\text{\n(\text{nolimits})}((l' \times k, \mathbb{Z})$, $\beta \in \text{Mat}\text{\n(\text{nolimits})}(l' \times l, \mathbb{Z})$ such that
$a'\alpha = \beta a$. Especially, this morphism is an isomorphism if and only if
both $\alpha$ and $\beta$ are invertible. So the well-known Smith Theorem implies
that every object $a \in \mathcal{F}_{2.1}$ is isomorphic to one presented by a diagonal
matrix diag \text{nolimits} $(q_1, q_2, \ldots, q_r)$. Hence, every polyhedron from $\mathcal{F}_2$
is isomorphic to a bouquet of cones $\bigvee_i Cq_i$, where we identify an integer
$q$ with the corresponding map $S^2 \to S^2$. Moreover, if $q = uv$, where
$\gcd(u, v) = 1$, then
$$Cq \cong C \begin{pmatrix} 1 & 0 \\ 0 & q \end{pmatrix} \cong C \begin{pmatrix} u & 0 \\ 0 & v \end{pmatrix} \cong Cu \vee Cv.$$ 

Therefore, $Cq$ can only be indecomposable if $q = p^s$, where $p$ is prime.
On the other hand, the exact sequence of homologies arising from the
triangle
\begin{equation}
S^2 \xrightarrow{\partial} S^2 \xrightarrow{\eta} M^3(q) \to S^3
\end{equation}
that $H_2(Cq) \cong \mathbb{Z}/q$ and $H_3(Cq) = 0$. Hence, Lemma 2.5 implies that
$Cq$ is indecomposable. Therefore, the atoms in $\mathcal{F}_2$ are just $Cq$ for
$q = p^s$ with a prime $p$. These atoms are denoted by $M^3(q)$ and their
susensions $S^kM^3(q)$ by $M^{k+3}(q)$. The atoms and suspended atoms
$M^d(q)$ are called Moore space.\textsuperscript{1} [12]. We also write $M^d_s$ instead of
$M^d(2^s)$ (these atoms play a special role later).

We can calculate the groups Hos$(M^3(q), M^3(q'))$. Since $\pi_3^S(S^2) \cong \mathbb{Z}/2$ [20, Theorem 15.1], the exact sequences for the functor Hos\n arising from the triangles (3.1) for $q$ and $q'$ imply that
$$\text{Hos}(S^2, M^3(q)) \cong \text{Hos}(M^3(q), S^3) \cong \mathbb{Z}/q,$$
$$\text{Hos}(S^3, M^3(q)) \cong \text{Hos}(M^3(q), S^2) \cong \begin{cases} \mathbb{Z}/2 & \text{if } q \text{ is even}, \\ 0 & \text{if } q \text{ is odd}, \end{cases}$$
$$\text{Hos}(M^3(q), M^3(q')) \cong \mathbb{Z}/(q, q') \text{ if } q \text{ or } q' \text{ is odd,}$$

\textsuperscript{1}In [20], Section XI.10 they are denoted by $P_q^d$ and called pseudo-projective
spaces.
and there is an exact sequence

\[(3.2)\]
\[0 \to \mathbb{Z}/2 \to \text{Hos}(M^3_s, M^3_r) \to \mathbb{Z}/2^m \to 0, \quad \text{where } m = \min(r, s).\]

Note that the endomorphism rings \(\text{Es}(M^3(q))\) are finite, hence, local. These considerations immediately imply the description of polyhedra from \(\mathcal{S}_2\).

**Theorem 3.1.** Every polyhedron from \(\mathcal{S}_2\) uniquely (up to permutation of summands) decomposes into a bouquet of spheres \(S^2, S^3\) and Moore atoms \(M^3(q)\).

We also need the following fact.

**Proposition 3.2.**

\[\pi^S_4(M^3(q)) \simeq \begin{cases} 
0 & \text{if } q \text{ is odd}, \\
\mathbb{Z}/4 & \text{if } q = 2, \\
\mathbb{Z}/2 \oplus \mathbb{Z}/2 & \text{if } q = 2^s, \ s > 1.
\end{cases}\]

**Proof.** Recall that \(\pi^S_4(S^3) \simeq \pi^S_4(S^2) \simeq \mathbb{Z}/2\) [20, Theorems 15.1, 15.2]. Therefore, the exact sequence for \(\pi^S_4\) arising from (3.1) shows that \(\pi^S_4(M^3(q)) = 0\) for \(q\) odd and, for \(q = 2^s\), there is an exact sequence

\[0 \to \mathbb{Z}/2 \to \pi^S_4(M^3_s) \to \mathbb{Z}/2 \to 0.\]

Note that \(\pi^S_4(M^3_1) \simeq \pi_6(M^3_1)\), so [20, Lemma 10.2] implies that it embeds into \(\pi_6(S^3) \simeq \mathbb{Z}/12\) [20, Theorem 16.1]. Hence, \(\pi^S_4(M^3_3) \simeq \mathbb{Z}/4\). For \(r > 1\) consider the commutative diagram of triangles

\[(3.3)\]
\[\begin{array}{cccc}
S^2 & \xrightarrow{2^r} & S^2 & \xrightarrow{2^{r-1}} \to M^3_1 & \to S^3 \\
1 \downarrow & & 1 \downarrow & & 1 \downarrow \\
S^2 & \xrightarrow{2^r} & S^2 & \xrightarrow{2^{r-1}} \to M^3_s & \to S^3,
\end{array}\]

It induces the commutative diagram with exact rows

\[
\begin{array}{cccc}
0 & \to \mathbb{Z}/2 & \to \pi^S_4(M^3_1) & \to \mathbb{Z}/2 & \to 0 \\
0 & \downarrow & \downarrow & \downarrow & 1 \\
0 & \to \mathbb{Z}/2 & \to \pi^S_4(M^3_s) & \to \mathbb{Z}/2 & \to 0,
\end{array}
\]

which shows that the second row is the pushdown of the first one along zero map, hence, it splits. \(\square\)

**Proposition 3.3.**

\[\text{Hos}(M^d_s, M^d_r) \simeq \begin{cases} 
\mathbb{Z}/4 & \text{if } r = s = 1, \\
\mathbb{Z}/2 \oplus \mathbb{Z}/2^m & \text{otherwise, where } m = \min(r, s).
\end{cases}\]
Proof. Obviously, we may suppose that \( m = 3 \). Since \( \pi^3_4(M^3_1) \cong \mathbb{Z}/4 \) is a module over the ring \( \text{Hos}(M^3_1, M^3_1) \), \( 2 \text{Hos}(M^3_1, M^3_1) \neq 0 \), hence, \( \text{Hos}(M^3_1, M^3_1) \cong \mathbb{Z}/4 \). On the other hand, applying the functor \( \text{Hos}(\_, M^3_1) \) to the diagram (3.3) with \( s > 1 \), we get a commutative diagram with exact rows:

\[
0 \longrightarrow \mathbb{Z}/2 \longrightarrow \text{Hos}(M^3_1, M^3_1) \longrightarrow \mathbb{Z}/2 \longrightarrow 0
\]

Thus its second row is the pull-back of the first one along the zero map, hence, it splits. The dual consideration shows that the sequence (3.2) for \( r > 1 \) can be obtained as a pushdown of the sequence for \( r = 1 \), hence, it splits too.

\[
\begin{array}{ccc}
0 & \longrightarrow & \mathbb{Z}/2 \\
\uparrow & & \uparrow \\
0 & \longrightarrow & \text{Hos}(M^3_1, M^3_1) & \longrightarrow & \mathbb{Z}/2 & \longrightarrow & 0.
\end{array}
\]

Thus its second row is the pull-back of the first one along the zero map, hence, it splits. The dual consideration shows that the sequence (3.2) for \( r > 1 \) can be obtained as a pushdown of the sequence for \( r = 1 \), hence, it splits too.

Note that the latter decomposition in this statement is that of groups. Taking into account the multiplication, it is convenient to present morphisms \( M^d_s \rightarrow M^d_t \) as triangular matrices \( \begin{pmatrix} a & b \\ 0 & c \end{pmatrix} \), with \( a \in \mathbb{Z}/2^r \), \( b \in \mathbb{Z}/2 \), \( c \in \mathbb{Z}/2^r \), \( 2^{s-m} a \equiv 2^{r-m} c \mod 2^\mu \), where \( m = \min(s, r), \mu = \max(s, r) \). The product of morphisms correspond then to the usual product of matrices, while the sum of morphisms correspond to the usual sum of matrices, with the only exception, when \( s = r = 1 \): then we must add matrices as follows:

\[
\begin{pmatrix} a & b \\ 0 & a \end{pmatrix} + \begin{pmatrix} a' & b' \\ 0 & c' \end{pmatrix} = \begin{pmatrix} a + a' & b + b' + aa' \\ 0 & a + a' \end{pmatrix}.
\]

Let now \( n = 3, m = 1 \), then \( \mathcal{J}_3 = \mathcal{A}_{3,1} \uparrow \mathcal{B}_{3,1} \), where \( \mathcal{A}_{3,1} = S^3 \mathcal{I}_1 \) and \( \mathcal{B}_{3,1} = S^3 \mathcal{I}_2 \). Hence, polyhedra from \( \mathcal{A}_{3,1} \) are just bouquets of spheres \( S^4 \), while those from \( \mathcal{B} \) are bouquets of spheres \( S^4, S^3 \) and Moore spaces \( M^4(q) \). For convenience, we set \( M^0_0 = S^4 \) and \( M^\infty_0 = S^3 \) and order the set of indices by the rule \( 1 < 2 < \cdots < \infty < 0 \). As we have seen, \( \text{Hos}(S^4, M^4(q)) = 0 \) for \( q \) odd, \( \text{Hos}(S^4, M^4) = H_r \cong \mathbb{Z}/2 \) for \( r \neq 0 \) and \( \text{Hos}(S^4, S^4) = H_0 \cong \mathbb{Z} \). Therefore, a map \( a : A \rightarrow B \), where \( A \in \mathcal{A}, B \in \mathcal{B} \) can be presented as a block matrix:

\[
a = \begin{pmatrix} a_0 \\ a_\infty \\ \vdots \\ a_2 \\ a_1 \end{pmatrix},
\]

where \( a_s \) are matrices over \( H_s \). One easily sees that if \( \eta_s \) is a generator of \( H_s \) and \( \beta_r : M^4_s \rightarrow M^4_r \), then \( \beta_r \eta_s = 0 \) if \( r > s \), while for \( r \leq s \) the
map $\beta_{rs}$ can be so chosen that $\beta_{rs}\eta_s = \eta_r$. Set

$$H_{rs} = \begin{cases} 
0 & \text{if } r > s, \\
\mathbb{Z}/2 & \text{if } 0 \neq r \leq s, \\
\mathbb{Z} & \text{if } s = r = 0.
\end{cases}$$

Therefore two matrices $a, a'$ of the form (3.4) define isomorphic objects from $B\text{im}(S_3, 1)$ if and only if there is an invertible integral matrix $\alpha$ and an invertible block matrix $\beta = \beta_{rs}$, where $\beta_{rs}$ is a matrix over $H_{rs}$, such that $a' = \beta a \alpha^{-1}$. Then simple considerations show that every object from $B\text{im}(S_3, 1)$ decomposes into a direct sum of objects given by the $1 \times 1$ matrices $q \in H_0$, $\eta_r \in H_r$, $r \neq 0$ and $(2^s \eta_r) \in H_0 \oplus H_r$, $r \neq 0$, $s > 0$. The first case corresponds to the Moore space $M^5(q)$, while the second and the third cases define new polyhedra, respectively, $C^5(2^r \eta)$, $C^5(\eta 2^s)$ and $C^5(2^r \eta 2^s)$, given by the gluing diagrams

![Gluing diagrams](image)

(The words in brackets show the corresponding gluings.)

To find endomorphisms of these atoms, note that there are triangles

(3.5) \[ S^3 \vee S^4 \xrightarrow{\eta} S^3 \rightarrow C^5(2^r \eta) \rightarrow S^4 \vee S^5, \]

(3.6) \[ S^4 \xrightarrow{2^s \eta} S^3 \vee S^4 \rightarrow C^5(\eta 2^s) \rightarrow S^5, \]

(3.7) \[ S^3 \vee S^4 \xrightarrow{2^r \eta 2^s} C^5(2^r \eta 2^s) \rightarrow S^3 \vee S^4. \]

By Theorem 1.1, $\text{Es}(C^5(2^r \eta))$, up to an ideal $I$ such that $I^2 = 0$, is isomorphic to the endomorphism ring of the map $f = (2^r \eta)$ in the category $B\text{im}(S_3, 1)/\mathcal{J}$. An endomorphism of $f$ in $B\text{im}(S_3, 1)$ is a pair $(\alpha, \beta)$, where $\alpha = \begin{pmatrix} a & b \eta \\ 0 & c \end{pmatrix}$ ($a, c \in \mathbb{Z}, b \in \mathbb{Z}/2$), $\beta \in \mathbb{Z}$, such that $\beta f = f \alpha$, i.e. $\beta = a \equiv c$ mod 2. Moreover, one easily sees that $\mathcal{J}$ consists of the pairs with the first component $\begin{pmatrix} 2^r x & x \eta \\ 0 & 0 \end{pmatrix}$, whence $\text{Es}(C^5(2^r \eta))/I^2$ is isomorphic to the subring of $\mathbb{Z}/2^{r+1} \oplus \mathbb{Z}$ consisting of all pairs $(a, c)$ with $a \equiv c$ mod 2. This ring has no nontrivial idempotent, hence, $C^5(2^r \eta)$ is indeed indecomposable, hence, an atom. Moreover, using the triangle (3.5), one can see that $I \simeq \mathbb{Z}/2$ and...
$E_s(C^5(2^r \eta))$ is isomorphic to the ring of triangular matrices $\begin{pmatrix} a & b \\ 0 & c \end{pmatrix}$, where $a \in \mathbb{Z}/2^{r+1}$, $b \in \mathbb{Z}/2$, $c \in \mathbb{Z}$, $a \equiv c \mod 2$. The same result for $E_s(C^5(\eta 2^r))$ follows from the triangle (3.6). Finally, one gets from the triangle (3.7) that $E_s(C^5(2^r \eta 2^s))$ is isomorphic to the ring of triangular matrices $\begin{pmatrix} a & b \\ 0 & c \end{pmatrix}$, where $a \in \mathbb{Z}/2^r$, $b \in \mathbb{Z}/2$, $c \in \mathbb{Z}/2^s$, $a \equiv c \mod 2$. Therefore these polyhedra are also atoms. They are called Chang atoms Moreover, the last ring is local, thus the multiplicity of $C^5(2^r \eta 2^s)$ (as well as of any its shift) in a decomposition of a polyhedron into a bouquet of indecomposables is the same for all such decompositions. Note that the same is true for suspended atoms $M^d(q)$. On the other hand, the triangles (3.5) and (3.6) imply that $H_3(C^5(2^r \eta)) \simeq H_4(C^5(\eta 2^r)) \simeq \mathbb{Z}/2^r$, while other homologies of these spaces are zero. Altogether, it gives the following description of the category $\mathcal{I}_3$.

**Theorem 3.4 (Whitehead–Chang, [25, 11]).** Any polyhedron from $\mathcal{I}_3$ uniquely (up to permutation of summands) decomposes into a bouquet of spheres $S^3, S^4, S^5$, suspended Moore atoms $M^4(q), M^5(q)$ and Chang atoms $C^5(\eta), C^5(2^r \eta), C^5(\eta 2^r)$ and $C^5(2^r \eta 2^s)$.

Using terms from the representation theory, one can say that the categories $\mathcal{I}_n$, $n \leq 3$, are discrete (or essentially finite). In this context it means that there are only finitely many isomorphism classes of polyhedra in $\mathcal{I}_n$ with a prescribed exponent of the torsion part of homologies. (So it looks similar to the description of finitely generated abelian groups.)

4. **Tame case: Baues–Hennes Theorem**

We study now the category $\mathcal{I}_4$. By Theorem 2.2 $\mathcal{I}_4 = \mathcal{A} \uparrow \mathcal{B}$, where $\mathcal{A} = S^3 \mathcal{I}_2$, $\mathcal{B} = S^2 \mathcal{I}_2$. By Theorem 3.1 every polyhedron from $\mathcal{A}$ (from $\mathcal{B}$) is a bouquet of spheres $S^5, S^6$ and Moore atoms $M^6(q)$ (respectively, $S^4, S^5$ and $M^5(q)$). We have already calculated morphisms between indecomposables in $\mathcal{I}_2$. Just in the same way one calculates morphisms from the objects of $S^3 \mathcal{I}_2$ and those of $S^2 \mathcal{I}_2$. We omit the details, which are standard; the result is presented in Table 1. Actually, the groups $\text{Hos}(M^6, M^5)$ can be naturally considered as the groups of upper triangular matrices $\begin{pmatrix} a & b \\ 0 & c \end{pmatrix}$ over $\mathbb{Z}/2$ with $b = 0$ if $s = r = 1$. Again the sum of morphisms correspond to the usual sum of matrices, with the exceptions for $s > 1, r = 1$ and $s = 1, r > 1$, when
Table 1.

|       | $S^5$ | $S^6$ | $M_1^6$ | $M_s^6 (s > 1)$ |
|-------|-------|-------|---------|-----------------|
| $S^4$ | $\mathbb{Z}/2$ | $\mathbb{Z}/2$ | $\mathbb{Z}/4$ | $\mathbb{Z}/2 \oplus \mathbb{Z}/2$ |
| $S^5$ | $\mathbb{Z}$ | $\mathbb{Z}/2$ | $\mathbb{Z}/2$ | $\mathbb{Z}/2$ |
| $M_1^5$ | $\mathbb{Z}/2$ | $\mathbb{Z}/4$ | $\mathbb{Z}/2 \oplus \mathbb{Z}/2$ | $\mathbb{Z}/4 \oplus \mathbb{Z}/2$ |
| $M_r^5 (r > 1)$ | $\mathbb{Z}/2$ | $\mathbb{Z}/2 \oplus \mathbb{Z}/2$ | $\mathbb{Z}/2 \oplus \mathbb{Z}/4$ | $\mathbb{Z}/2 \oplus \mathbb{Z}/2 \oplus \mathbb{Z}/2$ |

The sum of matrices must be twisted as follows:

\[
\begin{pmatrix}
a & b \\
0 & c
\end{pmatrix} + \begin{pmatrix}
a' & b' \\
0 & c'
\end{pmatrix} = \begin{pmatrix}
a + a' & b + b' + aa' \\
0 & c + c'
\end{pmatrix}
\]

if $s > 1, r = 1$, 

\[
\begin{pmatrix}
a & b \\
0 & c
\end{pmatrix} + \begin{pmatrix}
a' & b' \\
0 & c'
\end{pmatrix} = \begin{pmatrix}
a + a' & b + b' + cc' \\
0 & c + c'
\end{pmatrix}
\]

if $s = 1, r > 1$.

The multiplication of elements from $\text{Hos}(M_s^6, M_r^5)$ by morphisms between objects from $\mathcal{A}$ and $\mathcal{B}$ (also presented by triangular matrices as in Section 3) correspond to the usual product of matrices. Therefore, a morphism $A \rightarrow B$ can be naturally considered as a block matrix presented in Table 2. In this table a symbol 2 (∞) shows that the corresponding block has values from $\mathbb{Z}/2$ (respectively, from $\mathbb{Z}$). Zeros show that the corresponding block is always zero. Arrows on the left
and below symbolize the action of morphisms between the objects from \( A \) and \( B \) respectively. The labels \((1), (2), \ldots\) (or \((1), (2), \ldots\)) show that the corresponding horizontal (respectively, vertical) stripes are of the same size and we must use the same elementary transformations in both of them. These stripes correspond to \( M^d_\varphi \) with the same \( d \) and \( r \). Note that there are 2 horizontal and 2 vertical stripes without such labels. They correspond to spheres \( S^d \).

This matrix problem is a slight variation of a well-known one, namely, representations of bunches of chains (see [9] or [10, Appendix B]). It implies a description of indecomposable objects in the category \( \text{Bim} (\mathcal{S}_4, 2) \), hence, in \( \mathcal{S}_4 \). We call them strings and bands, as it is usual in the representation theory of algebras. Not providing details (see [15]), we just present the corresponding attachment diagrams (Table 3). It is convenient to distinguish two types of strings: usual and decorated; I hope that the pictures show the difference. “Decorations” (one for each string) are shown with double lines. We omit integers precising the degrees of “vertical” attachments, as well as one precising the “long” attachment in a decorated strings of the first kind; they can be arbitrary and differ for different attachments. Certainly, each diagram is actually finite: it starts at any place on the left and stops at any place on the right.

Multiple bullets in the case of bands symbolize not a unique cell but several (say \( m \)) copies of it (the same for each ball). All attachments except the one marked by the wavy line are “natural”: the first copy of an upper cell is attached to the first copy of a lower one, the second to the second, etc. The attachment marked by the wavy line is “twisted” by an invertible Frobenius matrix \( \Phi \) of size \( m \times m \) over the field \( \mathbb{Z}/2 \) with the characteristic polynomial \( f(x) \), which must be a power of an irreducible one and such that \( f(0) \neq 0 \). For instance, if \( f(x) = x^3 + x + 1 \), i.e. \( m = 3 \) and \( \Phi = \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 1 \end{pmatrix} \), this attachment is:

One can check that all strings and bands are indecomposable and pairwise non-isomorphic. Note also that all atoms from \( \mathcal{S}_4 \) are \( p \)-primary (2-primary, except Moore atoms \( M_d^{p^{r}}(p^{r}) \) with odd \( p \), which are \( p \)-primary). Therefore, we have the uniqueness of decomposition of spaces from \( \mathcal{S}_4 \) into bouquets of suspended atoms. So we get the following result. We call strings and bands Baues atoms.
Theorem 4.1 (Baues–Hennes [8]). Any polyhedron from $\mathcal{I}_4$ decomposes uniquely into a bouquet of spheres, suspended Moore atoms, suspended Chang atoms and Baues atoms.
In Section 4 we shall see that actually $\mathcal{S}_4$ is the last case where a "good" description of polyhedra is possible. Starting from $\mathcal{S}_5$ this problem becomes wild.

5. Torsion free polyhedra. Finite case

Consider now torsion free case. Note that if all $H_k(X)$ are torsion free, the attachment diagram cannot contain “Moore fragments”

\[ \begin{array}{c}
\end{array} \]

In particular, among the atoms from Sections 3 and 4 only Chang atom $C_5 = C^5(\eta)$ and the double Chang atom $C_2^7 = C^7(\eta^2)$ with the attachment diagram

\[ \begin{array}{c}
7 \\
6 \\
5 \\
4 \\
\end{array} \]

are torsion free. Therefore, if we set in Theorem 2.4 $n = 5, m = 4$, the category $\mathcal{A}^0$ consists of bouquets of spheres $S^8$ and the category $\mathcal{B}^0$ consists of bouquets of spheres $S^d$ ($5 \leq d \leq 8$), suspended Chang atoms $C^7, C^8$ and suspended double Chang atoms $C_2^8$. Obviously, $\mathcal{A}^0(S^8, S^8) = 0$. Easy calculation give the following values of the groups $\Gamma(B) = \mathcal{A}^0(S^8, B)$ for atoms $B$ from $\mathcal{B}^0$:

| $B$ | $S^5$ | $S^6$ | $S^7$ | $C^7$ | $C^8$ | $C_2^8$ |
|-----|-------|-------|-------|-------|-------|---------|
| $\Gamma$ | $\mathbb{Z}/24$ | $\mathbb{Z}/2$ | $\mathbb{Z}/2$ | $\mathbb{Z}/12$ | 0 | $\mathbb{Z}/12$ |

Morphisms of these spaces induce monomorphisms $\Gamma(S^7) \to \Gamma(C^7) \to \Gamma(S^5)$ and $\Gamma(S^6) \to \Gamma(S^5)$, epimorphism $\Gamma(S^5) \to \Gamma(C_2^8)$, and isomorphisms $\Gamma(S^7) \to \Gamma(S^6)$ and $\Gamma(S^7) \to \Gamma(S^6)$. Thus, an object from $\text{Bim}(\mathcal{A}^0_{5,4})$ can be presented by a block matrix as in Table 4. Here inside each blocks we have written the groups, wherefrom the coefficients of this block are. The arrows show the allowed transformation between blocks. An integer $k$ in the arrows point out that, when we perform this transformation, the row must be multiplied by $k$. (No integer means that $k = 1$.) For instance, we can add the rows of the third matrix multiplied by 2 to the rows of the first one. Certainly, compositions of these transformations are also allowed. Thus, for instance, we can add the rows of the third matrix multiplied by 2 to the rows of the second one too. The arising matrix problem is rather simple. It is of finite type, and Table 6 shows the attachment diagrams of the corresponding atoms from $\mathcal{T}_5$. We call them $A$-atoms of the 1st kind. The integer $v$ show, which multiple of the generator of the group $\pi_8^S(S^5) \simeq \mathbb{Z}/24$ is
used for the “long” attachment. Actually, $1 \leq v \leq 12$ in the case of $A(v)$, $1 \leq v \leq 3$ in the case of $A(\eta v \eta)$, $1 \leq v \leq 6$ in all other cases. So we have got a description of polyhedra from $\mathcal{F}_5$.

**Theorem 5.1** (Baues–Drozd [4]). Every polyhedron from $\mathcal{F}_5$ is a bouquet of spheres, suspended Chang and double Chang atoms, and the $A$-atoms of the first kind.
Note that this time the decomposition is not unique; even the cancellation law does not hold. For instance, $A(3) \oplus S^5 \simeq A(9) \oplus S^5$ \cite{[4][15]}; see ibidem more on decomposition laws.

Analogous is the case of $\mathcal{T}_6$, when we take $m = 4$. We omit details, just schematically presenting the arising matrix problem in Table 6. The dashed line from the 4th to the 6th level show the transformation that only acts on the left-hand column (on $\mathbb{Z}/2$ components). The resulting list of atoms (their attachment diagrams) see in the

\begin{table}[h]
\centering
\begin{tabular}{|c|c|}
\hline
$\mathbb{Z}/24$ & 0 \\
$\mathbb{Z}/12$ & 0 \\
$\mathbb{Z}/12$ & 0 \\
$\mathbb{Z}/2$ & $\mathbb{Z}/2$ \\
0 & $\mathbb{Z}/2$ \\
$\mathbb{Z}/2$ & $\mathbb{Z}/24$ \\
0 & $\mathbb{Z}/12$ \\
\hline
\end{tabular}
\caption{Table 6.}
\end{table}

Table 7. We call them \textit{A-atoms of the second kind}. The integers $v$ and $w$ show, as above, the multiple of generator, respectively, of $\pi^S_9(S^6)$ and $\pi^S_{10}(S^7)$ used for the corresponding attachments. In all cases $v, w \in \{1, 2, 3, 4, 5, 6\}$.

So we have got a description of polyhedra from $\mathcal{T}_6$.

\textbf{Theorem 5.2} (Baues–Drozd \cite{[7]}). \textit{Every polyhedron from $\mathcal{T}_6$ is a bouquet of spheres, suspended Chang and double Chang atoms, suspended A-atoms of the first kind and A-atoms of the second kind.}

In the next section we shall use the values of $\text{Hos}$-groups between Chang atoms and spheres. To deal with the Chang atom $C^5$ we apply the bifunctor $\text{Hos}$ to the cofibration sequence

\begin{equation}
S^4 \xrightarrow{\eta} S^3 \to C^5 \to S^5 \xrightarrow{\eta} S^4.
\end{equation}
It gives the commutative diagram with exact rows and columns (we write here \((X, Y)\) instead of \(\text{Hos}(X, Y)\))

\[
\begin{array}{ccccccc}
\mathbb{Z} & \longrightarrow & \mathbb{Z}/2 & \longrightarrow & (C^5, S^4) & \longrightarrow & 0 & \longrightarrow & \mathbb{Z} \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
\mathbb{Z}/2 & \longrightarrow & \mathbb{Z}/2 & \longrightarrow & (C^5, S^4) & \longrightarrow & \mathbb{Z} & \longrightarrow & \mathbb{Z}/2 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
(S^4, C^5) & \longrightarrow & (S^5, C^5) & \longrightarrow & (C^5, C^5) & \longrightarrow & (S^3, C^5) & \longrightarrow & (S^4, C^5) \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
0 & \longrightarrow & \mathbb{Z} & \longrightarrow & (C^5, S^5) & \longrightarrow & 0 & \longrightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
\mathbb{Z} & \longrightarrow & \mathbb{Z}/2 & \longrightarrow & (C^5, S^4) & \longrightarrow & 0 & \longrightarrow & \mathbb{Z},
\end{array}
\]
where all maps $\mathbb{Z} \to \mathbb{Z}/2$ are surjective and all maps $\mathbb{Z}/2 \to \mathbb{Z}/2$ are bijective. It gives the following values of $\text{Hos}$-groups:

\[
\begin{align*}
\text{Hos}(\mathbb{C}^5, S^4) &= \text{Hos}(S^4, \mathbb{C}^5) = 0, \\
\text{Hos}(S^3, \mathbb{C}^5) &= \text{Hos}(\mathbb{C}^5, S^5) = \mathbb{Z}, \\
\text{Hos}(\mathbb{C}^5, S^3) &= \text{Hos}(S^5, \mathbb{C}^5) = 2\mathbb{Z}, \\
\text{Hos}(\mathbb{C}^5, \mathbb{C}^5) &= \mathbb{D}.
\end{align*}
\]

where $\mathbb{D}$ (the “dyad”) is the subrings of $\mathbb{Z} \times \mathbb{Z}$ consisting of all pairs $(a, b)$ with $a \equiv b \mod 2$.

Similar observations applied to the suspended versions of the sequence (5.1) and the cofibration sequence

\[
S^6 \xrightarrow{\eta^2} S^4 \rightarrow C^7 \xrightarrow{\eta^2} S^7 \rightarrow S^5
\]

give Table 8 of the values $\text{Hos}(X, Y)$ for suspended atoms from $\mathcal{T}_4$. In Table 8.

|      | $S^4$ | $C_2^7 : 4$ | $C_6 : 4$ | $S^5$ | $C_7^7 : 5$ | $S^6$ | $S^7$ |
|------|-------|-------------|-----------|-------|-------------|-------|-------|
| $S^4$| $\mathbb{Z}$| $2\mathbb{Z}$| $\mathbb{Z}/12$| $2\mathbb{Z}$| $0$| $\mathbb{Z}/12$| $\mathbb{Z}/2$| $\mathbb{Z}/24$|
| $C_2^7 : 4$| $\mathbb{Z}$| $\mathbb{Z}/12$| $2\mathbb{Z}$| $0$| $\mathbb{Z}/12$| $0$| $\mathbb{Z}/12$|
| $C_6^7 : 4$| $\mathbb{Z}$| $\mathbb{Z}/12$| $\mathbb{Z}/12$| $0$| $\mathbb{Z}/12$| $0$| $\mathbb{Z}/12$|
| $C_7^7 : 5$| $\mathbb{Z}$| $\mathbb{Z}/12$| $\mathbb{Z}/12$| $0$| $\mathbb{Z}/12$| $0$| $\mathbb{Z}/12$|
| $S^5$| $0$| $0$| $\mathbb{Z}$| $2\mathbb{Z}$| $0$| $\mathbb{Z}/2$| $\mathbb{Z}/2$|
| $C_7^7 : 7$| $0$| $0$| $\mathbb{Z}$| $0$| $\mathbb{Z}/12$| $0$| $\mathbb{Z}/12$|
| $S^6$| $0$| $0$| $\mathbb{Z}/2$| $\mathbb{Z}$| $0$| $\mathbb{Z}/2$| $\mathbb{Z}/2$|
| $S^7$| $0$| $0$| $\mathbb{Z}$| $0$| $\mathbb{Z}/2$| $\mathbb{Z}$| $\mathbb{Z}$|

this table the $\text{Hos}$-groups for suspended Chang atoms are presented in matrix form, emphasizing which components have come from the cells of given dimensions. The superscripts $\mathbb{Z}$ show that the diagonal parts of the corresponding matrices are with entries not from $\mathbb{Z} \times \mathbb{Z}$, but from
For instance, \( \mathcal{E}(C_7) \) is presented as the ring of triangular matrices 
\[
\begin{pmatrix}
  a & b \\
  0 & c
\end{pmatrix},
\]
where \( a, c \in \mathbb{Z}, \ a \equiv c \text{ mod } 2, \ b \in \mathbb{Z}/12 \). Under such presentation the multiplication of morphisms turns into the multiplication of matrices.

6. Torsion free polyhedra. Tame case

The category \( \mathcal{T}_7 \) is more complicated. To describe it, we use Theorem 2.4 with \( n = 7, m = 3 \). Then \( \mathfrak{A}^0 \) consists of the bouquets of spheres \( S^d \) (\( 10 \leq d \leq 12 \)) and suspended Chang atoms \( C^{12} \), while \( \mathfrak{B}^0 \) consists of bouquets of spheres \( S^d \) (\( 7 \leq d \leq 10 \)) suspended Chang atoms \( C^9, C^{10} \) and suspended double Chang atoms \( C^{10}_2 \). The calculations similar to those of the end of preceding section give Table 9 of the values of groups \( \mathcal{S}(X,Y) \) for the suspended atoms \( X \in \mathfrak{A}^0 \) and \( Y \in \mathfrak{B}^0 \), also presented in matrix form. The superscripts * show that in the corresponding groups we identify the elements of order 2. So actually, these values are isomorphic to \( \mathbb{Z}/24 \), but it is convenient to consider them as \((\mathbb{Z}/24 \oplus \mathbb{Z}/2)/(12,1)\). Then again the action of

|        | \( S^{10} \) | \( S^{11} \) | \( S^{12} \) | \( C^{12} : 10 \) | \( 12 \) |
|--------|--------------|--------------|--------------|----------------|--------|
| \( S^7 \) | \( \mathbb{Z}/24 \) | 0 | 0 | \( \mathbb{Z}/24 \) | 0 |
| \( C^{10}_2 : 7 \) | 0 | 0 | \( \mathbb{Z}/24^* \) | 0 |
| 10 | 0 | 0 | \( \mathbb{Z}/2 \) | 0 | \( \mathbb{Z}/2^* \) |
| \( C^9 : 7 \) | \( \mathbb{Z}/12 \) | 0 | 0 | \( \mathbb{Z}/24^* \) | 0 |
| 9 | 0 | 0 | \( \mathbb{Z}/24 \) | 0 | \( \mathbb{Z}/2^* \) |
| \( S^8 \) | \( \mathbb{Z}/2 \) | \( \mathbb{Z}/24 \) | 0 | 0 | 0 |
| \( C^{10} : 8 \) | 0 | \( \mathbb{Z}/12 \) | 0 | 0 | 0 |
| 10 | 0 | 0 | 0 | 0 | 0 |
| \( S^9 \) | \( \mathbb{Z}/2 \) | \( \mathbb{Z}/2 \) | \( \mathbb{Z}/24 \) | 0 | \( \mathbb{Z}/12 \) |
| \( S^{10} \) | 0 | \( \mathbb{Z}/2 \) | \( \mathbb{Z}/2 \) | 0 | 0 |
morphisms from \( \mathcal{A}^0 \) and \( \mathcal{B}^0 \), as presented in Table 8 (or, rather, its suspended version) turns into the multiplication of matrices. Again we obtain a bimodule problem close to that of bunches of chains, especially, in its "decorated" version (see [17]). To present the answer (for details see [16]), we introduce the following notations and definitions.

Definition 6.1.  (1) We consider chains \( \mathcal{E}_k \) and \( \mathcal{F}_k \) (1 \( \leq k \leq 4 \)):

\[
\begin{align*}
\mathcal{E}_1 &= \{ e_1 < e_2 < e_4 \}, & \mathcal{F}_1 &= \{ f_4 < f_1 \}, \\
\mathcal{E}_2 &= \{ e_5 < e_9 \}, & \mathcal{F}_2 &= \{ f_3 < f_5 \}, \\
\mathcal{E}_3 &= \{ e_6 < e_7 \}, & \mathcal{F}_3 &= \{ f_2 \}, \\
\mathcal{E}_4 &= \{ e_3 < e_{10} < e'_9 < e'_6 \}, & \mathcal{F}_4 &= \{ f'_1 < f'_2 < f'_3 \}.
\end{align*}
\]

Actually, the elements \( e_i \) (\( f_j \)) correspond to the rows (columns) of Table 9, while the relations \( ^c \) correspond to the elements of the groups \( \mathcal{C}^0(A, B) \). We need extra elements \( e'_i \) and \( f'_j \) since the entries \( \mathbb{Z}/2 \) in this table behave in a different way than the other ones.

We set \( \mathcal{E} = \bigcup_{i=1}^4 \mathcal{E}_i \), \( \mathcal{F} = \bigcup_{i=1}^4 \mathcal{F}_i \), \( \mathcal{X} = \mathcal{E} \cup \mathcal{F} \). \( x \approx y \) means that \( x \) and \( y \) belong to the same set \( \mathcal{E}_i \) or \( \mathcal{F}_i \).

(2) We define symmetric relations \( \sim \) and \( \prec \) on \( \mathcal{X} \) setting \( x \prec y \) if \( x \in \mathcal{E}_i \), \( y \in \mathcal{F}_i \) or vice versa; \( e_i \sim e'_j (i \in \{6,9\}, f_j \sim f'_j \) (1 \( \leq j \leq 3 \)). We also define the symmetric relations \( ^c \), where \( c \in \{1, 2, 3, 4, 6\} \), setting \( e_i \overset{c}{=} f_j \) if \( e_i - f_j \) and the \((ij)\)-th entry in Table 9 is \( \mathbb{Z}/m \) with \( c | m \). We denote by \( R \) the set of all relations \( \{\sim, \overset{c}{=}\} \) and by \( v(c) \) the biggest \( d \) such that \( 2^d \) divides \( c \).

(3) We define a word as a sequence \( w = x_1 r_2 x_2 r_3 \ldots r_l x_l \) where \( x_i \in \mathcal{X}, r_i \in R \) such that

(a) \( x_{k-1} r_k x_k \) in \( \mathcal{X} \) for each 1 \( \leq k \leq l \);
(b) if \( r_k = \sim \), then \( r_{k+1} = \overset{c}{=} \) and vice versa;
(c) if \( r_2 = \overset{c}{=} \) (respectively, \( r_l = \sim \)), there is no element \( y \in \mathcal{X} \) such that \( x_1 \sim y \) (respectively, \( x_l \sim y \));
(d) if \( r_k = \overset{c}{=} \) with \( v(c) = 1 \), then either 2 \( < k < l \), or \( k = 2, x_1 = e_1 \), or \( k = l, x_l = x_1 \).
(e) if $r = \overline{c}$ with $v(c) = 2$, then $r$ can only occur in the following words or their reverse:

\[
\begin{align*}
e_4 & \sim e_5rf_3 \sim \ldots \text{ (of any length)}, \\
e_1rf_4 & \sim f_5, \ e_3 \sim e_2rf_4 \sim f_5, \\
& \ldots \sim e_4 \sim e_5rf_3 \sim \ldots \text{ (of any length)}, \\
e_1rf_4 & \sim f_5 \overline{c} \sim \ldots \text{ (of any length)}, \\
e_3 & \sim e_2rf_4 \sim f_5 \overline{c} \sim \ldots \text{ (of any length)}, \\
e_1rf_4 & \sim f_5 \overline{c} \sim \ldots \text{ (of any length)}, \\
e_1rf_1 & \sim f_1', \ e_0' \sim e_0rf_2 \sim f_2', \ e_0' \sim e_9rf_3 \sim f_3',
\end{align*}
\]

where $c' \equiv 0 \pmod{3}$;

(f) if $w$ contains a subword $e_i \equiv f_j, \ c \in \{3,9\}$ or its reverse, it does not contain any subword $e_i' \equiv f_j, \ c' \not\equiv 0 \pmod{3}, \ e_i \approx e_i' \equiv f_j$ (equivalently, $f_j \approx f_j')$ or its reverse.

Here the reverse to the word $w$ is the word $w^* = x_1r_lx_{l-1} \ldots x_2r_2x_1$.

We call $l$ the length of the word $w$.

(4) We define a cycle as a pair $z = (w, r_1)$, where $w$ is a word such that $r_2 = r_l = \overline{c}$ and $r_k \not\equiv \overline{c}$ with $v(c) = 2$, while $r_1 = \overline{c}$ with $v(c) \not= 2$ and $x_1r_1x_1$ in $X$. For such a cycle we set $x_{ql+k} = x_k$ and $r_{ql+k} = r_k$ for any $q$ and $1 \leq k \leq l$.

(5) The $m$-th shift of the cycle $z = (w, r_1)$ is defined as the cycle $z^{(m)} = (w^{(m)}, r_{2m+1})$, where $w^{(m)} = x_{2m+1}r_2x_{2m+2} \ldots r_{2m}x_{2m}$.

(6) A cycle $(w, r_1)$ is called periodic if $w$ is of the form $w = vr_1vr_1 \ldots r_1v$ for a shorter cycle $(v, r_1)$.

(7) We call two words, $w$ and $w' = x_1r_2x_2r_3' \ldots r_1'x_1$ (with the same $x_k$), elementary congruent if there are two indices $k_1, k_2$ such that

\[
\begin{align*}
rc & = \overline{c}, \ \ \ rkc = \overline{d} \quad \text{for some } \ c \not= 3, \ d \not= 3, \\
r'c_1 & = \overline{c}, \ \ \ r'kc_2 = \overline{d}, \\
r'c_k & = r_k \quad \text{for } k \not\in \{k_1, k_2\}, \\
x_{k_1} & \approx x_{k_2} \text{ or } x_{k_1} \approx x_{k_2-1}.
\end{align*}
\]

(8) We call two words $w, w'$ congruent and write $w \equiv w'$ if there is a sequence of words $w = w_1, w_2, \ldots, w_n = w$ such that $w_k$ and $w_{k+1}$ are elementary congruent for $1 \leq k < n$. We call two cycles $z = (w, r_1)$ and $z' = (w', r_1')$ congruent and write $z \equiv z'$ if $w' \equiv z$ and $r_1' = r_1$. 

We recall that two polyhedra \( X, Y \) are called congruent if \( X \lor Z \simeq Y \lor Z \) for some polyhedron \( Z \). Then we write \( X \equiv Y \).

**Theorem 6.2.**  
(1) Every word \( w \) defines an indecomposable polyhedron \( P(w) \) from \( \mathcal{T}_7 \), called string polyhedron.
(2) Let \( \pi(t) \neq t \) be an irreducible polynomial over the field \( \mathbb{Z}/2 \).
Every triple \( (z, \pi(t), m) \), where \( z \) is a non-periodic cycle and \( m \in \mathbb{N} \), defines an indecomposable polyhedron \( P(z, \pi, m) \) from \( \mathcal{T}_7 \), called band polyhedron.
(3) Every indecomposable polyhedron from \( \mathcal{T}_7 \) is congruent either to a string or to a band one.
(4) \( P(w) \equiv P(w') \) if and only if either \( w' \equiv w \) or \( w' \equiv w^* \).
(5) \( P(z, \pi(t), m) \equiv P(z', \pi'(t), m) \) if and only if \( m = m' \) and one of the following possibilities hold:
(a) \( \pi'(t) = \pi(t) \) and either \( z' \equiv z^{(k)} \) with \( k \) even or \( z' = z^{*(k)} \) with \( k \) odd;
(b) \( \pi'(t) = t^d \pi(1/t) \), where \( d = \deg \pi \), and either \( z' = z^{(k)} \) with \( k \) odd or \( z' = z^{*(k)} \) with \( k \) even.
(6) Neither string polyhedron is congruent to a band one.
(7)

The cofibration sequence
\[
A \xrightarrow{f} B \rightarrow C f \rightarrow S A, \quad A \in \mathcal{A}^0, \; B \in \mathcal{B}^0,
\]
and the attachment diagram of a string polyhedron \( P(w) \) is constructed as follows.

(1) The indecomposable summands of \( A \) correspond to the following subwords of \( w \) (or their reverse):
\[
\begin{align*}
S^{10} & \text{ to } f_1 \sim f'_1, \\
S^{11} & \text{ to } f_2 \sim f'_2, \\
S^{12} & \text{ to } f_3 \sim f'_3, \\
C^{12} & \text{ to } f_4 \sim f_5.
\end{align*}
\]

(2) The indecomposable summands of \( B \) correspond to the following subwords of \( w \) (or their reverse):
\[
\begin{align*}
S^7 & \text{ to } e_1, \\
C^{10}_2 & \text{ to } e_2 \sim e_3, \\
C^9 & \text{ to } e_4 \sim e_5, \\
S^8 & \text{ to } e_6 \sim e'_6, \\
C^{10} & \text{ to } e_7, \\
S^9 & \text{ to } e_9 \sim e'_9, \\
S^{10} & \text{ to } e_{10}.
\end{align*}
\]
(3) The attachments correspond to the subwords $e_i - f_j$ (or their reverse). Namely, such an attachment starts at the $f$-end of the corresponding subword and ends at its $e$-end; the number $c$ shows which multiple of the generator of the $(ij)$-th group from Table 9 must be taken.

For instance, if

$$w = e_{10} - f_2^1 \sim f_2 - e_6 \sim e_6' - f_1^1 \sim f_1 - e_4$$
$$\sim e_5 - f_5 \sim f_4^1 - e_2 \sim e_3 - f_3^1 \sim f_3 - e_5$$
$$\sim e_4 - f_1 \sim f_1^1 - e_9 \sim e_9 - f_3 \sim f_3'$$

the polyhedron $P(w)$ has the attachment diagram

Let now $P(z, \pi(t), m)$ be a band polyhedron. Replacing $w$ by $w^*$, we may suppose that $x_1 \in E$, $x_n \in F$. Let also $\Phi$ be the Frobenius matrix with the characteristic polynomial $\pi(t)^m$. Then the cofibration sequence and the attachment diagram are constructed as follows.

1. Do the construction as above for the word $w$.
2. Replace every summand $A_j$ of $A$ and every summand $B_i$ of $B$ by $m$ copies of it, $A_{j1}, \ldots, A_{jm}$ and $B_{i1}, \ldots, B_{im}$.
3. If there was an attachment $A_j^c \rightarrow B_i$, replace it by the attachments $A_{jk}^c \rightarrow B_{ik}$ $(1 \leq k \leq m)$.
4. If $A_j$ is the last summand of $A$, $B_i$ is the first summand of $B$ and $r_1 = -$, add new attachments $A_{jk}^c \rightarrow B_{id}$ in all cases, when the $(lk)$-th coefficient of the matrix $\Phi$ is nonzero.

For instance, consider the band polyhedron $P(z, t^2 + t + 1, 3)$ $z = (w, -)$, where

$$w = e_2 \sim e_3 - f_3^1 \sim f_3 - e_9 \sim e_9' - f_1^1 \sim f_1 - e_4 \sim e_6 - f_5 \sim f_4$$
Then the attachment diagram is

Here the double lines show the attachments like

while the wavy line shows the attachment

ruled by the Frobenius matrix with the characteristic polynomial $\pi(t)^2 = t^4 + t^2 + 1$, namely,

$$
\begin{pmatrix}
0 & 0 & 0 & 1 \\
0 & 1 & 0 & 0 \\
0 & 1 & 0 & 1 \\
0 & 0 & 1 & 0
\end{pmatrix}.
$$

7. Wild cases

Since we are dealing with additive categories that are not categories over a field, we have to precise the notion of wildness. The following one seems to work in all known cases.

**Definition 7.1.** We call an additive category $\mathcal{C}$ wild if, there is a field $\mathbb{k}$ such that for every finitely generated $\mathbb{k}$-algebra $\Lambda$ there is a full subcategory $\mathcal{C}_\Lambda \subseteq \mathcal{I}$ and an equivalence $\mathcal{C}_\Lambda \rightarrow \Lambda\text{-mod}$ (the category of $\Lambda$-modules that are finite dimensional over $\mathbb{k}$).

One can see that for algebras over a field this definition is equivalent to the usual one (see, for instance [14]). One can also easily show that if a category $\mathcal{D}$ is wild and there is an equivalence $\mathcal{C}' \rightarrow \mathcal{D}$ for a full subcategory $\mathcal{C}' \subseteq \mathcal{C}$, then $\mathcal{C}$ is wild as well.

Now we present the results on wildness of categories $\mathcal{I}_n$ and $\mathcal{J}_n$.

**Theorem 7.2** (Baues [6]). If $n > 4$, the category $\mathcal{I}_n$ is wild.

**Proof.** Obviously, one only has to prove the claim for $n = 5$. The category $\mathcal{I}_5$ contains the full subcategory $\mathcal{C} = \mathcal{A}\uparrow\mathcal{B}$, where $\mathcal{A}$ consists of bouquets of suspended Moore atom $A = M^6(2)$ and $\mathcal{B}$ consists of bouquets of suspended Moore atoms $B = M^8(2)$. Let $\mathcal{Y} = \mathcal{A}\uparrow\mathcal{B}$. Since
Hos(B, A) = 0, Corollary 1.2 is applicable. Moreover, the ideal I in this case is zero, so \( C/I \simeq \text{Bim}(\mathcal{V}) \) with \( I^2 = 0 \), hence, the natural functor \( C \to \text{Bim}(\mathcal{V}) \) is an epivalence.

Consider the cofibration sequence

(7.1) \( S^7 \xrightarrow{2} S^7 \to A \to S^8 \xrightarrow{2} S^8 \).

Apply to it the functors Hos(\( A, S^6 \)) and Hos(\( B, S^6 \)). Taking into account the Hopf map \( \eta: S^6 \to S^5 \) we get the commutative diagram with exact rows

\[
\begin{array}{cccccc}
0 & \to & \mathbb{Z}/2 & \to & \text{Hos}(A, S^6) & \to & \mathbb{Z}/2 & \to & 0 \\
\eta_* & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \to & \mathbb{Z}/2 & \to & \text{Hos}(A, S^5) & \to & \mathbb{Z}/2 & \to & 0.
\end{array}
\]

Since \( \eta^3 = 4 \nu \), where \( \nu \) is the element of order 8 in Hos(\( S^8, S^5 \)), the map \( \eta_* \) in this diagram is zero, therefore, the lower exact sequence splits and Hos(\( A, S^5 \)) \simeq \mathbb{Z}/2 \oplus \mathbb{Z}/2. Quite similarly, one shows that Hos(\( S^8, B \)) \simeq \mathbb{Z}/2 \oplus \mathbb{Z}/2. Now apply the functors Hos(\( A, S^5 \)) and Hos(\( B, S^5 \)) to the exact sequence (7.1) and take into account the map \( S^5 \to B \) form the definition of \( B = M^6(2) \). Since Hos(\( S^7, B \)) \simeq \mathbb{Z}/2, we get the commutative diagram with exact rows

\[
\begin{array}{cccccc}
0 & \to & \mathbb{Z}/2 & \to & \text{Hos}(A, S^5) & \to & \mathbb{Z}/2 & \to & 0 \\
& & \downarrow i & & \downarrow & & \downarrow & & \\
0 & \to & \mathbb{Z}/2 \oplus \mathbb{Z}/2 & \to & \text{Hos}(A, B) & \to & \mathbb{Z}/2 & \to & 0.
\end{array}
\]

We know that the upper row of this diagram splits. Hence, the lower row splits too, so Hos(\( A, B \)) \simeq (\mathbb{Z}/2)^3. Recall that Es(\( A \)) \simeq Es(\( B \)) \simeq \mathbb{Z}/4 (Proposition 3.3). Hence, there is an equivalence \( \text{Bim}(\mathcal{V}) \to \Lambda\text{-mod} \), where \( \Lambda \) is the path algebra of the quiver \( \bullet \rightleftharpoons \bullet \) over the field \( \mathbb{Z}/2 \). The latter is well-known to be wild, therefore, so is also \( \mathcal{I}_5 \). \( \square \)

**Theorem 7.3** ([16]). The category \( \mathcal{I}_n \) is wild for \( n > 7 \).

**Proof.** Again we only have to prove it for \( n = 8 \). The category \( \mathcal{I}_8 \) contains the full subcategory \( \mathcal{C} = \mathcal{A} \downarrow \mathcal{V} \mathcal{B} \), where \( \mathcal{A} \) consists of bouquets of Chang atoms \( C^4_{12} \) and \( \mathcal{B} \) consists of bouquets of spheres \( \mathbb{S}^8 \) and \( \mathbb{S}^1_{11} \), and \( \mathcal{V} = \mathcal{A} \downarrow \mathcal{S}^8 \downarrow \mathcal{A} \). Moreover, \( \mathcal{I}^0_{8,3} \cap \text{Bim} \mathcal{V} = 0 \), so there is an equivalence \( \mathcal{C} \to \text{Bim}(\mathcal{V}) \). Consider the cofibration sequence

\[
S^{13} \xrightarrow{\mathcal{L}} S^{11} \to C^2_{14} \to S^{14} \to S^{12}
\]

and apply to it the functor Hos(\( A, S^{11} \)). We get the exact sequence

\[
\mathbb{Z}/2 \xrightarrow{(\eta^3)^*} \mathbb{Z}/24 \to \text{Hos}(C^2_{14}, S^{11}) \to \mathbb{Z} \to \mathbb{Z}/2.
\]
wherefrom \( \mathcal{S}^0(C^1_2, S^1_1) \simeq \mathbb{Z}/12 \). Moreover, there is a commutative diagram of cofibration sequences

\[
\begin{array}{ccccccc}
S^{13} & \xrightarrow{\eta} & S^{12} & \longrightarrow & C^{14} & \longrightarrow & S^{14} & \xrightarrow{\eta} & S^{13} \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
S^{13} & \xrightarrow{\eta^2} & S^{11} & \longrightarrow & C^{14} & \longrightarrow & S^{14} & \xrightarrow{\eta^2} & S^{12}.
\end{array}
\]

Applying the functor \( \text{Hos}(\_, S^8) \), we get the commutative diagram with exact rows

\[
\begin{array}{ccccccc}
0 & \longrightarrow & \mathbb{Z}/2 & \longrightarrow & \text{Hos}(C^{14}_2, S^8) & \longrightarrow & \mathbb{Z}/24 & \longrightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \downarrow \\
0 & \longrightarrow & \mathbb{Z}/2 & \longrightarrow & \text{Hos}(C^{14}_2, S^8) & \longrightarrow & 0 & \longrightarrow & 0.
\end{array}
\]

(Recall that \( \pi^{S^8}_{d+4}(S^d) = \pi^{S^8}_{d+5}(S^d) = 0 \) and \( \pi^{S^8}_{d+6}(S^d) = \mathbb{Z}/2 \). Therefore, \( \mathcal{S}^0(C^1_2, S^8) \simeq \mathbb{Z}/24 \oplus \mathbb{Z}/2 \). So we present maps \( a \in \mathcal{V}(A, B) \), where \( A \in \mathcal{A}, B \in \mathcal{B} \), as block-triangular matrices

\[
a = \begin{pmatrix}
a_1 & a_2 \\
0 & a_3
\end{pmatrix},
\]

where \( a_1 \) is with the coefficients from \( \mathbb{Z}/24 \), \( a_2 \) is with coefficients from \( \mathbb{Z}/2 \) and \( a_3 \) with coefficients from \( \mathbb{Z}/12 \). On the other hand, maps \( \alpha : A \rightarrow A' \), where \( A, A' \in \mathcal{A} \), and \( \beta : B \rightarrow B' \), where \( B, B' \in \mathcal{B} \) can be presented by block-triangular matrices

\[
\alpha = \begin{pmatrix}
\alpha_1 & \alpha_2 \\
0 & \alpha_3
\end{pmatrix} \quad \text{and} \quad \beta = \begin{pmatrix}
\beta_1 & \beta_2 \\
0 & \beta_3
\end{pmatrix},
\]

where \( \alpha_2 \) has coefficients from \( \mathbb{Z}/12 \), \( \beta_2 \) has coefficients from \( \mathbb{Z}/24 \), other blocks have components from \( \mathbb{Z} \) and \( \alpha_1 \equiv \alpha_3 \mod 2 \).

We consider the full subcategory \( \mathcal{C} \subseteq \text{Bim}(\mathcal{V}) \) consisting of all maps \( a \) such that the corresponding blocks \( a_1, a_2, a_3 \) are of the form

\[
a_1 = \begin{pmatrix}
6I & 0 & 0 \\
0 & 12 & 0
\end{pmatrix}, \quad a_2 = \begin{pmatrix}
0 & I & 0 \\
0 & 0 & u
\end{pmatrix} \quad \text{and} \quad a_3 = \begin{pmatrix}
6v_1 & 6v_2 & 0
\end{pmatrix},
\]

where the entries \( I \) stand for identity matrices (not necessary of the same dimensions) and \( u, v_1, v_2 \) are arbitrary matrices with coefficients from \( \mathbb{Z}/2 \) of proper sizes. We write \( a = a(u, v_1, v_2) \). One can verify that if \( (\alpha, \beta) \) is a morphism \( a(u, v_1, v_2) \rightarrow a(u', v_1', v_2') \), there are integral matrices \( \gamma_1, \gamma_2, \gamma_3 \) such that \( v_i\gamma_1 = \gamma_2 v_i \) \( (i = 1, 2) \) and \( u\gamma_3 = \gamma_1 u \). Conversely, any given triple \( \gamma_1, \gamma_2, \gamma_3 \) with these properties can be accomplished to a morphism \( a(u, v_1, v_2) \rightarrow a(u', v_1', v_2') \). It gives rise to an equivalence \( \mathcal{C} \rightarrow \Lambda\text{-mod} \), where \( \Lambda \) is the path algebra of the quiver \( \bullet \rightarrow \bullet \rightarrow \bullet \rightarrow \bullet \). It is known to be wild. Therefore, \( \mathcal{S}_8 \) is wild as well.

\[\square\]
