A remote C–C bond cleavage–enabled skeletal reorganization: Access to medium-/large-sized cyclic alkenes

Lei Li,* Zhong-Liang Li,* Qiang-Shuai Gu, Na Wang, Xin-Yuan Liu†

Although great success has been achieved in selective C–C bond cleavage via the intramolecular radical remote migration process of several carbon-based groups, the development of the radical-based remote vinyl migration process remains a formidable challenge because of the energetically unfavorable process. To address this problem, we report here, for the first time, a novel C–C bond reorganization strategy via an unprecedented radical 1,3-, 1,4-, or 1,5-vinyl migration triggered by various types of fluoroalkylation of alkenes for the efficient realization of 1,2-fluoroalkylalkenylation reaction. This strategy provides an expedient and broadly applicable platform to access skeletally and functionally diverse fluoroalkyl-containing medium- and large-sized cyclic alkenes with excellent chemo-, regio-, and stereoselectivity. The broad substrate scope, which covers distinctly electron-neutral or electron-deficient alkyl migrating groups and various fluoroalkyl radical precursors, the excellent functional group tolerance, the remarkable selectivity, and the operational simplicity, as well as versatile transformations of the products, make this approach practical and attractive.

INTRODUCTION

Medium- and large-sized cyclic alkenes are one of the most prominent classes of structural motifs because they are not only prevalent in a wide range of biologically active natural products and therapeutic agents (1–5) but can also serve as a vital platform for diverse chemical functionalization given their unique and versatile chemical reactivity (6). Nevertheless, their elegant synthesis remains a formidable challenge with conventional cyclization or cycloaddition strategies, mainly due to unfeasible transannular interactions and entropic and/or enthalpic factors (7–13). To solve these problems, a revolutionary advancement in this field is the establishment of transition metal–catalyzed ring-closing metathesis, which has served as a reliable tool for the synthesis of otherwise hardly accessible complex medium- and large-sized cyclic alkenes (14–22). However, high-dilution and/or slow-addition operation has been frequently required to inhibit the undesired competitive oligomerization via intermolecular olefin metathesis. Therefore, developing a novel and operationally simple alternative strategy to construct these cyclic alkenes still remains a great need.

During the past few decades, selective C–C bond cleavage via the intramolecular radical remote migration process of carbon-based groups like aryl, cyano, or carbonyl groups has attracted much attention (Fig. 1A) (23–31). It is not only one of the most challenging themes at the intersection of both radical and rearrangement reactions but also represents an efficient tool for the preparation of complex organic molecules based on reorganization of the skeletons of readily available compounds (23–31). However, to the best of our knowledge, the radical-based remote vinyl migration process has rarely been approached, largely because of the energetically unfavorable β-scission process of intermediate B compared with that of other migration reactions aforementioned based on density functional theory calculations (Fig. 1A) (32). On the other hand, the increasing importance of fluoroalkyl-containing molecules in the development of pharmaceuticals and agrochemicals as well as materials has inspired considerable research efforts in discovering new practical perfluoroalkylation strategies for their synthesis (33–38). In particular, radical-mediated 1,2-difunctionalization of unactivated alkenes has emerged as one of the most powerful tools for the assembly of diverse fluoroalkyl-containing molecules (39–50). Despite these impressive advances, the fluoroalkylalkenylation of unactivated alkenes for the simultaneous incorporation of fluoroalkyl and alkyl group into unactivated alkenes has never been reported. To achieve olefinic fluoroalkylalkenylation and efficiently attain the aforementioned synthetically formidable medium- and large-sized cyclic alkenes, we wondered whether a novel C–C bond reorganization strategy might be achieved via an unprecedented remote vinyl migration triggered by selective addition of fluoroalkyl radicals to one alkene in the substrate bearing two alkyl groups (Fig. 1B). In this scenario, we expected that various in situ-generated fluoroalkyl radical species might selectively attack to the less sterically hindered terminal alkene to provide a transient alkyl radical II. Driven by the formation of a lower-energy neutral ketyl radical III, the subsequent exo cyclization and β-scission of intermediate II might lead to remote radical vinyl migration/ring expansion sequence to deliver the fluoroalkylalkylated medium-/large-sized cyclic alkenes. However, several challenges would be associated with the development of such a process: (i) Because the initial radical RF is inherently reactive and neutral (51, 52), its addition to alkene could be complicated in both chemoselectivity and regioselectivity in the presence of two alkyl enones of substrate. (ii) Several competitive pathways, such as common kinetically favorable β-scission to deliver intermediate IV, endo cyclization to generate intermediate V, and exo-cyclization–initiated other side reactions to provide VI and VII, should be overcome (32, 53–55). (iii) A high degree of E/Z selectivity for the final alkene product should be achieved. Here, we describe the first successful development of a novel C–C bond reorganization strategy via an unprecedented radical 1,3-, 1,4-, or 1,5-vinyl migration. With such a strategy, 1,2-trifluoromethylalkenylation of unactivated alkenes has been successfully achieved with excellent chemo-, regio-,
and stereoselectivity (Fig. 1C, left). This strategy has also provided a general and operationally simple approach for the synthesis of skeletal and functionally diverse fluoroalkylated medium-/large-sized cyclic alkenes or bridged ring systems, which constitute the core structures of many biologically active natural products, such as siamol (1), spartidienedione (2), tuberculariol D (4), longpene B (5), etc. (Figs. 1C, right, and 2).

**RESULTS**

**Reaction condition optimization**

First, substrate 1A was easily obtained by adding allylzinc chloride to (E)-4-phenylbut-3-en-2-one at −78°C. We then initiated our investigation for radical remote vinyl migration on linear substrate 1A with commercially available Togni’s reagent 2 (56) as a CF₃ radical source. We were delighted to find that the desired 1,2-trifluoromethylalkenylation product 3A was obtained in 55% yield with excellent E/Z selectivity in the presence of CuI [10 mol percent (mol %)] at 80°C in 24 hours via an unprecedented 1,3-vinyl migration process (Table 1, entry 1). Further screening of reaction parameters (Table 1, entries 2 to 15), through variation of the copper catalysts, the molar ratio of the reactants, organic solvents, reaction temperature, and time, has led to the identification of the optimal reaction conditions as follows: The reaction of 1A and 2 with a molar ratio of 1.0:2.4 (2 was added in two portions with a time interval of 10 hours) in the presence of CuCN (10 mol %) in 1,4-dioxane at 80°C for 20 hours to afford 3A in 69% yield (entry 15). Note that the
intramolecular radical 1,3-migration process of other carbon-based groups has rarely been achieved in previously reported processes, probably due to the strained four-membered cyclic transition state involved in this process (26, 31). In sharp contrast, the present radical vinyl migration process was surprisingly viable enough to accommodate such an unfavorable pathway, thus substantially expanding the scope of carbon-functionalized alkenyl groups into alkenes. To this end, we rationally designed the cyclic styrene-type alkene 1 as a template to selectively afford the desired product 2 bearing a quaternary carbon center in 65% yield. Note that the reaction with 1 and 1K exhibited excellent chemoselectivity for the radical vinyl migration over other potential phenyl or hydrogen migration process to selectively afford 3 and 3K, respectively. Next, 1,4- and 1,5-vinyl migration were examined to expand the synthetic utility of this methodology. Gratifyingly, under the reaction conditions similar to those of the 1,3-vinyl migration process, a wide range of linear alkens 1L and 1Q and aryl-tethered alkens 1M to 1P having different electronic and geometric features were all found to be suitable substrates to afford expected products 3L to 3Q in 30 to 78% yields. The excellent chemoselectivity for vinyl migration over phenyl migration was also observed for 1,4- and 1,5-vinyl migration, as proven by the exclusive formation of 3L, 3P, and 3Q from the corresponding substrates. To further evaluate the utility of the vinyl migration, we carried out the preparative-scale synthesis of 3A. As demonstrated in Fig. 3, there was almost no change on the chemical yield (63%), indicating that this protocol should be potentially useful in large-scale chemical production. Overall, the 1,2-trifluoromethylalkenylation of alkenols features a broad compatibility for a diverse range of substrates through an unprecedented 1,3-, 1,4-, or 1,5-vinyl migration with excellent selectivity, thus providing the first straightforward and attractive strategy for concomitantly efficient installation of valuable trifluoromethyl and diversely functionalizable alkynyl groups into alkenes.

Encouraged by the above success, we thus switched our efforts toward the synthetically challenging medium- and large-sized cyclic alkenes. To this end, we rationally designed the cyclic styrene-type alkenols, which are easily prepared by adding the organolithium reagent to the corresponding alkene. To this end, we rationally designed the cyclic styrene-type alkene 1 as a template to selectively afford the desired product 2 bearing a quaternary carbon center in 65% yield. Note that the reaction with 1 and 1K exhibited excellent chemoselectivity for the radical vinyl migration over other potential phenyl or hydrogen migration process to selectively afford 3 and 3K, respectively. Next, 1,4- and 1,5-vinyl migration were examined to expand the synthetic utility of this methodology. Gratifyingly, under the reaction conditions similar to those of the 1,3-vinyl migration process, a wide range of linear alkens 1L and 1Q and aryl-tethered alkens 1M to 1P having different electronic and geometric features were all found to be suitable substrates to afford expected products 3L to 3Q in 30 to 78% yields. The excellent chemoselectivity for vinyl migration over phenyl migration was also observed for 1,4- and 1,5-vinyl migration, as proven by the exclusive formation of 3L, 3P, and 3Q from the corresponding substrates. To further evaluate the utility of the vinyl migration, we carried out the preparative-scale synthesis of 3A. As demonstrated in Fig. 3, there was almost no change on the chemical yield (63%), indicating that this protocol should be potentially useful in large-scale chemical production. Overall, the 1,2-trifluoromethylalkenylation of alkenols features a broad compatibility for a diverse range of substrates through an unprecedented 1,3-, 1,4-, or 1,5-vinyl migration with excellent selectivity, thus providing the first straightforward and attractive strategy for concomitantly efficient installation of valuable trifluoromethyl and diversely functionalizable alkynyl groups into alkenes.

Encouraged by the above success, we thus switched our efforts toward the synthetically challenging medium- and large-sized cyclic alkenes. To this end, we rationally designed the cyclic styrene-type alkenols, which are easily prepared by adding the organolithium reagent to the corresponding alkene.
preparing macrocyclic alkenes was demonstrated by the isolation of the 14-membered alkene 5E in 46% yield. To increase the diversity of products, we then investigated the construction of benzannulated medium-sized cyclic alkenes via radical 1,4-vinyl migration (Fig. 4B). Under the standard reaction conditions, the expected benzannulated 9- and 10-membered alkenes 5F to 5J were obtained in 41 to 52% yields from the corresponding substrates bearing different opening-ring sizes and distinctly electronic groups at different positions on the aryl ring directly connected with the migrating alkene. The structure of product 5I was firmly established by x-ray crystallographic analysis (fig. S2). Furthermore, the reaction of the eight-membered substrate 4K proceeded smoothly to deliver the benzannulated 11-membered alkene 5K in 31% yield as a 4:1 mixture of E/Z isomers under the standard reaction conditions. Note that the external alkenol 4L was also suitable for the vinyl migration reaction to deliver the nine-membered product 5L with an external C==C double bond in 60% yield as a 5:1 mixture of E/Z isomers (Fig. 4C). To demonstrate the practicality of this process, we performed the preparative-scale synthesis of 5A, as depicted in Fig. 4. The chemical yield of 5A was not significantly influenced (59%), suggesting that this protocol should be potentially useful in large-scale production of medium-sized cyclic alkenes.

To further enrich the functional group diversity at the alkenyl positions, we subsequently examined substrates bearing polar olefin moieties. Much to our surprise, a phenylsulfonyl-substituted vinyl group successfully migrated under the standard reaction conditions to provide the eight-membered product 6 in 79% yield (Fig. 4D). The structure of 6 was carefully confirmed by x-ray crystallographic analysis (fig. S2). More encouragingly, electron-deficient alkenes conjugated with much more synthetically valuable cyano and ester groups both proved to be viable for migration, thus furnishing the corresponding products 7 and 8 in 58 and 60% yields, respectively.

The scope of the reaction was further expanded to other radical precursors. A variety of electronically distinct fluoroalkyl sulfonyl chlorides (57), such as trifluoromethyl, difluoromethyl, and even perfluorobutyl ones, were found to be suitable precursors via extrusion of sulfur dioxide in the presence of CuI (10 mol %) and Ag2CO3 (0.75 equiv.) to afford the expected products 6, 10, and 11 in 45 to 65% yields (Fig. 5A). Thus, the functional diversity of the synthesized medium-sized cyclic...
alkenes was further increased. On the other hand, substrate 4P bearing an electron-rich vinyl ether group underwent radical remote 1,5-vinyl migration to give the expected product 12, albeit in 12% yield along with the exo-cyclization product 13 in 43% yield (Fig. 5B), which is currently under further optimization in our laboratory. In addition, the formation of 13 also provided some indirect support for a stepwise remote vinyl migration pathway, as described in Fig. 1B.

**Versatile transformations**

The alkenyl and carbonyl moieties in the constructed medium-sized cyclic alkenes provide great potential for further transformations to deliver additional bonding and valuable functional groups, thus enhancing the complexity and diversity of products. In addition, the conformational preference of medium-sized cyclic alkenes may result in excellent stereocontrol for remote functional group manipulation (58). In this scenario, the dihydroxylation of 5A provided a bridged hemiketal 14 in 62% yield with excellent diastereoselectivity (Fig. 6A), which is quite similar to the core structure of tuberculariol D. The selective reduction of the carbonyl group of 5A by LiAlH4 delivered the alcohol 15 in 82% yield with a high diastereoselectivity of 15:1 (Fig. 6B). Furthermore, the epoxidation of 5A, 5C, and 5D with mCPBA (m-chloroperbenzoic acid) all efficiently afforded the corresponding medium-sized cyclic epoxides 16, 17, and 18, respectively, with excellent diastereoselectivity (>20:1) (Fig. 6C).
DISCUSSION

To gain some insights into the reaction mechanism, we conducted radical-trapping experiments conducted by using 2,2,6,6-tetramethyl-1-piperidinyloxy or benzoquinone as the radical scavengers under the standard conditions. The reactions were significantly inhibited by these reagents, suggesting that a radical process is involved under the current conditions (scheme S1). These experimental results, together with the observed exo-cyclization product for the substrate 4P (Fig. 5B), are in support of our initial proposal, as shown in Fig. 1B.

I n c o n c l u s i o n , w e h a v e s u c c e s s f u l l y a c h i e v e d a n o v e l C – C b o n d r e o r g a n i z a t i o n strategy via an unprecedented radical 1,3-, 1,4-, and 1,5-vinyl migration triggered by various types of fluoroalkylation of alkenes. This approach not only embodies a valuable 1,2-fluoroalkylalkenylation reaction of alkenes but also offers an attractive and broadly applicable platform to access skeletonally and functionally diverse perfluoroalkyl-containing 8- to 14-membered cyclic alkenes with excellent chemo-, regio-, and stereo-selectivity. In particular, this protocol features a broad substrate scope, including distinctly electron-neutral or electron-deficient alkenyl migrating groups and diverse perfluoroalkyl radical precursors, wide functional group compatibility, and operational simplicity. Furthermore, the high synthetic utility of the current process in organic and medicinal chemistry was showcased by straightforward manipulation of the alkene and carbonyl groups in thus obtained medium-sized cyclic alkene products with high diastereoselectivity. Detailed mechanistic studies and further expansion of this methodology are currently ongoing in our laboratory.

MATERIALS AND METHODS

Experimental design

All reactions were carried out under argon atmosphere using Schlenk techniques. Reagents were purchased from commercial sources and used as received. Analytical thin-layer chromatography (TLC) was performed on precoated silica gel 60 GF254 plates. Flash column chromatography was performed using Tsingdao silica gel (60; particle...
A 25-ml Schlenk tube equipped with a magnetic stir bar was charged with 1 (0.2 mmol, 1.0 equiv.), 2 (76 mg, 0.24 mmol, 1.2 equiv.), CuCN (1.8 mg, 0.02 mmol, 0.1 equiv.), and EtOAc (2.0 mL) under argon atmosphere. The sealed tube was then stirred at 60°C for 24 hours. After completion of the reaction as monitored by TLC, EtOAc (30 mL) was added, and the reaction mixture was washed with saturated NaHCO₃ (2.5 mL) solution. The organic layer was dried over anhydrous Na₂SO₄, filtered, and concentrated to afford a crude product, which was purified by flash column chromatography to afford products 3A to 3C, 3F, 3H, 3J, and 3K.

**Method C**
A 25-ml Schlenk tube equipped with a magnetic stir bar was charged with 1 (0.2 mmol, 1.0 equiv.), 2 (94.5 mg, 0.3 mmol, 1.5 equiv.), CuCN (1.8 mg, 0.02 mmol, 0.1 equiv.), and EtOAc (2.0 mL) under argon atmosphere. The sealed tube was then stirred at 60°C for 24 hours. After completion of the reaction as monitored by TLC, EtOAc (30 mL) was added, and the reaction mixture was washed with saturated NaHCO₃ (2.5 mL) solution. The organic layer was dried over anhydrous Na₂SO₄, filtered, and concentrated to afford a crude product, which was purified by flash column chromatography to afford products 3L to 3Q.
