Acknowledgments

First of all, I would like to thank my supervisor, Gustavo Alberto Burdman, for his encouragement and guidance throughout this project. I am deeply indebted to Department of Mathematical Physics at the University of Sao Paulo’s Physics Institute. I am also grateful to the elementary particle physics group, for its helpful tips, seminars and enjoyable discussions.

I would like to thank to my thesis committee members, Gustavo Burdman, Enrico Bertuzzo, Oscar José Pinto Éboli, Ricardo D’Elia Matheus and Sérgio Ferraz Novaes for their important comments.

In particular, thanks to my friends and colleagues, Leonardo Lima, Lindber Salas, Yuber, Denis, Boris, Gabi, Leila, Leonardo Duarte, Hugo Camacho for great discussions on elementary particle physics.

Thanks too to my undergraduate professors Jorge Abel Espichán Carrillo and Jaime Francisco Vento Flores and Jesús Félix Sánchez Ortiz who encouraged me in the area of physics.

I am very grateful to my parents, Sebastián Peralta, Cirila Cano for their unconditional support all along.

I would like to Acknowledge the financial support of the Committee for the Advancement of Higher Education (CAPES).
Abstract

The Standard model of particle physics provides a successful theory to understand the experimental results of the electroweak and strong interactions. However, it does not have a satisfactory explanation for the hierarchy problem. Many extensions of the Standard Model that solve the hierarchy problem result in new particles. We will study the phenomenology of vector-like fermions resulting in theories where the Higgs boson is typically a pseudo-Nambu-Goldstone boson. In these theories we study the case where a heavy fermion will be heavier than a heavy gluon, and then the channel of a heavy fermion decaying into a color octet is considered. We study this phenomenology at high energy colliders, both the LHC as well as future machines.

CHAPTER 1

Introduction

The Standard Model (SM) of elementary particle physics is a quantum field theory that describes the strong, weak and electromagnetic interactions between elementary particles. The gauge sector of the SM is $SU(3)_C \times SU(2)_L \times U(1)_Y$, where $SU(3)_C$ and $SU(2)_L \times U(1)_Y$ indicate the strong and electroweak interactions, respectively. In the SM the electroweak symmetry breaking (EWSB) $SU(2)_L \times U(1)_Y \rightarrow U(1)_{EM}$ (here $U(1)_{EM}$ corresponds to the electromagnetic interaction) is due to the Higgs sector. As a result, after the EWSB the weak vector bosons and the fermions obtain masses through the Higgs mechanism. In this mechanism the Higgs scalar field is a doublet of $SU(2)_L$ and it acquires a vacuum expectation value (VEV) such that the symmetry $SU(2)_L \times U(1)_Y$ is spontaneously broken.

The recent discovery of a scalar boson at the Large Hadron Collider (LHC) \cite{1,2} seems to indicate that it is the SM Higgs boson. If this particle is the Higgs boson of the SM then this discovery confirms that the SM is consistent. As a consequence of the measurements related to the SM \cite{3}, we now have direct evidence of all the SM spectrum.

Despite the success of the SM when compared with experiment \cite{3,4} we have many reasons to believe that the SM is not complete since, to say the least, gravity is not included. The SM does not provide a satisfactory explanation to the hierarchy problem \cite{5,6}. Here we focus on extensions of the SM that solve the hierarchy problem. In particular, we study quiver theories \cite{7,8,9,10,11,12} and their phenomenology. Using quiver theories \cite{5,13,14} as well as other similar theories where the Higgs is a pseudo-Nambu-Goldstone boson (pNGB).

We study the fermion excitations in these models by computing their masses and wave functions. Considering both cases left- and right-handed zero mode fermions, we will study the more relevant phenomenology.
To reproduce the phenomenology of these fermion excitations, we compute all their couplings. The one to the Higgs sector will be crucial to do the phenomenology. For instance, the coupling to the first excitations of the gauge bosons will be neglected, but only because we computed first and now we know they will play no role in the pair production.

We study the phenomenology of vector-like quarks at high energy Colliders. Prompted by our results in quiver theories, the vector-like quark can be heavier than the excited gluons, we study the phenomenology of production and decay of vector-like quark at the LHC and beyond taking into account the decay channel $T \rightarrow Gt$, with $Q$ the vector-like quark, $G$ the heavy gluon and $q$ a SM quark.

We start in chapter 2 by presenting the SM, jointly with the motivations to study physics beyond SM. In chapter 3 we briefly study one simple Little Higgs model [15] and introduce the quiver theories, for both gauge bosons and fermions. The Higgs is induced as a pNGB, by considering the quiver theory of EWSB. And then the couplings of fermions excited states were computed. In chapter 4 we study the phenomenology at the LHC of the excited heavy quarks in quiver theories, by using the most relevant couplings computed. In chapter 5 we begin to study the phenomenology of the heavy quarks at a future high energy Collider in a general vector-like theories. Finally we conclude and present the future studies in chapter 6.
CHAPTER 2

The Standard Model

The Standard Model (SM) of elementary particle physics is a quantum field theory that describes the electromagnetic, weak and strong interactions. The theoretical and experimental research in elementary particle physics in the 60s gave evidence of a possible unification of the weak and electromagnetic interactions, due to the fact that both are of vectorial nature and have universal couplings. In other words, they are both described by a gauge theory. Finally, between the years 60 and 70, the SM was first developed by Glashow, Weinberg and Salam, setting the foundations of our modern understanding of elementary particles.

The four basic ingredients necessary to the SM are: quarks, leptons, gauge bosons and the Higgs boson. All the electroweak and strong interactions are explained by gauge theories, namely the SM Lagrangian is invariant under the gauge transformations of $SU(3)_C \times SU(2)_L \times U(1)_Y$, for the strong and electroweak interactions respectively. We can study the strong interactions separately of the electroweak interactions, since both gauge sectors do not mix. The SM has a domain of applicability of at least several hundred of GeV. It is worth mentioning that not only works splendidly in theory, but it has also passed every experiment test so far. In addition, the model presents important symmetries in describing such interactions. In general, the symmetries have a central role in physics, namely, they protect some physical quantity and determine the dynamic structure of the fields. In this chapter, besides a brief introduction to the SM, we will present the gauge hierarchy problem and the problem of the hierarchy of SM fermion masses.
2.1 Quantum Chromodynamics

The sector of strong interactions of the SM better known as QCD is a non-Abelian gauge theory where generators belong to the local symmetry group $SU(3)_C$, and the internal degree of freedom is the named color. One of the properties of QCD is asymptotic freedom, that makes possible to use perturbative methods at very small distances \[16\]. The Lagrangian of QCD is

$$\mathcal{L} = -\frac{1}{4} F_{\mu\nu}^{i} F^{\mu\nu i} + \sum_{r} \bar{q}_{r\alpha} i\gamma_{\mu} \gamma_{5} q_{r}^{\beta}. \quad (2.1)$$

Notice that in (2.1), $r$ is the flavor index of quarks; the index of the adjoint representation is $i = 1, 2, \ldots, 8$ of 8 generators of $SU(3)_C$; $\alpha, \beta = 1, 2, 3$ are the indexes of the fundamental representation, these are the indexes of color, $q_r^{\beta}$ is a the quark field and $F_{\mu\nu}^{i}$ is the gauge field strength tensor which is given by

$$F_{\mu\nu}^{i} = \partial_{\mu} G_{\nu}^{i} - \partial_{\nu} G_{\mu}^{i} - g_{s} f_{ijk} G_{\mu}^{j} G_{\nu}^{k}. \quad (2.2)$$

In (2.2) the fields $G_{\mu}^{i}$ are the gluons fields and the structure constants $f_{ijk}$ ($i, j, k = 1, 2, \ldots, 8$) are defined by

$$[\lambda_{i}, \lambda_{j}] = 2i f_{ijk} \lambda^{k}. \quad (2.3)$$

The matrices $\lambda^{k}$ are the Gell-Mann matrices for $SU(3)$. The covariant derivative is given by

$$D_{\mu}^{\alpha} = \partial_{\mu} \delta_{\beta}^{\alpha} + \frac{1}{2} i g_{s} G_{\mu}^{i} \lambda_{\beta}^{i}, \quad (2.4)$$

with $g_{s}$ the gauge coupling constant in $SU(3)_c$ local. We should point out that the mass terms for the quarks fields will appear after the EW symmetry breaking.

2.2 Electroweak Model

The Glashow-Weinberg-Salam theory (GWS) where fermions are chiral is a gauge theory with symmetry $SU(2)_L \times U(1)_Y$, where $L$ and $Y$ represent the left-handed chirality with symmetry of weak isospin, and weak hypercharge, respectively. The left-handed leptons are

$$L_{e} = \begin{pmatrix} \nu_{e} \\ e^{-} \end{pmatrix}, \quad L_{\mu} = \begin{pmatrix} \nu_{\mu} \\ \mu^{-} \end{pmatrix}, \quad L_{\tau} = \begin{pmatrix} \nu_{\tau} \\ \tau^{-} \end{pmatrix}, \quad (2.5)$$

with weak isospin $I_{L} = 1/2$ and hypercharge $Y_{L_{L}} = -1$, and the right-handed leptons are

$$R_{e,\mu,\tau} = e_{R}, \mu_{R}, \tau_{R}, \quad (2.6)$$

with hypercharge $Y_{R_{L}} = -2$, where the hypercharge is given by the Gell-Mann and Nishijima relation $Q = I_{3} + (1/2)Y$. The SM does not include the right-handed
neutrinos because these have no SM gauge quantum numbers. The left-handed quarks are given by

\[ L_q^1 = \begin{pmatrix} u \\ d \end{pmatrix}_L \quad L_q^2 = \begin{pmatrix} c \\ s \end{pmatrix}_L \quad L_q^3 = \begin{pmatrix} t \\ b \end{pmatrix}_L, \]

(2.7)

with weak isospin \( I_q = 1/2 \) and hypercharge \( Y_{L_q} = 1/3 \). The right-handed quarks are

\[ R_u^{(1,2,3)} = u_R, c_R, t_R \]

(2.8)

and

\[ R_d^{(1,2,3)} = d_R, s_R, b_R \]

(2.9)

with \( Y_{R_u} = 4/3 \) and \( Y_{R_d} = -2/3 \), respectively.

Now, we write the Lagrangian \( \mathcal{L} \) that is invariant under the gauge symmetry \( SU(2)_L \times U(1)_Y \) in three parts, as follows

\[ \mathcal{L} = \mathcal{L}_G + \mathcal{L}_F + \mathcal{L}_H, \]

(2.10)

with

\[ \mathcal{L}_G = -\frac{1}{4} W^\mu_{\nu} W^{\mu\nu} - \frac{1}{4} B_{\mu\nu} B^{\mu\nu}, \]

(2.11)

where the field strength tensor \( W^\mu_{\nu} \) corresponds to the gauge symmetry \( SU(2)_L \), with coupling \( g \) and is given by

\[ W^\mu_{\nu} = \partial_\nu W^\mu - \partial_\mu W^\nu + g \varepsilon^{ijk} W^j_{\mu} W^k_{\nu}, \]

(2.12)

and the field strength tensor \( B_{\mu\nu} \) corresponds to the \( U(1)_Y \) field with coupling \( g' \) and is given by

\[ B_{\mu\nu} = \partial_\nu B_\mu - \partial_\mu B_\nu. \]

(2.13)

The kinetic term for the fermions is written in two parts

\[ \mathcal{L}_F = \mathcal{L}_{\text{leptons}} + \mathcal{L}_{\text{quarks}}, \]

(2.14)

that are given by

\[ \mathcal{L}_{\text{leptons}} = \overline{R}_\ell^n \ i \gamma^\mu \left( \partial_\mu + ig' 2 B_\mu Y \right) R^\ell_n \]

\[ + \overline{L}_\ell^n \ i \gamma^\mu \left( \partial_\mu + ig' 2 B_\mu Y + ig 2 \vec{\sigma} \cdot \vec{W}_\mu \right) \overline{L}_\ell^n, \]

(2.15)

where the index \( \ell \) represents the leptons (\( \ell = e, \mu, \tau \)); and the second term in (2.14) is
The Standard Model

\[ \mathcal{L}_{\text{quarks}} = R^a_u \gamma^\mu \left( \partial_\mu + \frac{g'}{2} B_\mu Y \right) R^a_u + R^a_d \gamma^\mu \left( \partial_\mu + \frac{g'}{2} B_\mu Y \right) R^a_d + \bar{L}^n_q \gamma^\mu \left( \partial_\mu + \frac{g}{2} \sigma \cdot W_\mu \right) L^n_q, \]  

(2.16)

where the index \( n \) is the index of generations \( (n = 1, 2, 3) \). In (2.15) and (2.16) \( \sigma \) represents the Pauli matrices:

\[
\sigma^1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma^2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma^3 = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}.
\]  

(2.17)

The Lagrangian (2.11) has four massless gauge bosons \( W^1_\mu, W^2_\mu, W^3_\mu \) and \( B_\mu \) because their mass terms are not invariant under gauge transformations. In addition, the gauge symmetry \( SU(2)_L \times U(1)_Y \) prohibits mass terms for fermions, since the left- and right-handed components of the fermionic fields transform in different ways under the \( SU(2)_L \times U(1)_Y \) gauge symmetry.

In the SM, the electroweak symmetry is spontaneously broken through the Higgs mechanism. This is done by introducing a scalar that is a doublet of \( SU(2)_L \), such that it includes two complex scalar fields as follows

\[ \Phi = \begin{pmatrix} \phi^+ \\ \phi^0 \end{pmatrix}, \]  

(2.18)

and with hypercharge \( Y_\Phi = 1 \). The Lagrangian for \( \Phi \) is given by

\[ \mathcal{L}_\Phi = (D^\mu \Phi)^\dagger (D_\mu \Phi) - V(\Phi^\dagger \Phi), \]  

(2.19)

where

\[ D_\mu = \partial_\mu + \frac{g'}{2} B_\mu Y + \frac{g}{2} \sigma \cdot W_\mu \]  

(2.20)

and the potential in \( \mathcal{L}_\Phi \) is

\[ V(\Phi^\dagger \Phi) = \mu^2 (\Phi^\dagger \Phi) + \lambda (\Phi^\dagger \Phi)^2. \]  

(2.21)

In the following, we will work with the ground state that minimizes the potential (2.21), considering the case for \( \mu^2 < 0 \). Then we can write the VEV for \( \Phi \) as follows:

\[ \langle \Phi \rangle_0 = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ v \end{pmatrix}, \]  

(2.22)
2.2 Electroweak Model

where $v = \sqrt{-\mu^2/\lambda}$. Using the nonlinear sigma model [17], jointly with (2.22), we parameterize the field $\Phi$ as

$$\Phi = \exp\left(\frac{i \xi^j(x) \sigma^j}{2v}\right) \begin{pmatrix} 0 \\ (v + h(x))/\sqrt{2} \end{pmatrix},$$  (2.23)

where $\sigma^j$ are Pauli matrices (2.17). But we will work in the unitary gauge, such that the Nambu-Goldstone Bosons (NGB's) $\xi^j$ can be removed by the following gauge transformation:

$$\Phi \rightarrow \exp\left(-\frac{i \xi^j(x) \sigma^j}{2v}\right)\Phi = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ v + h(x) \end{pmatrix},$$  (2.24)

so $\mathcal{L}_\Phi$ in (2.19) can be written in terms of physical fields as

$$\mathcal{L}_\Phi = \frac{1}{2} \partial_\mu h \partial_\mu h + \frac{g^2}{4} (v + h)^2 \left[ W_\mu^+ W^-_\mu + \frac{1}{2 \cos^2 \theta_W} Z_\mu Z^\mu \right] - \mu^2 \left(\frac{(v + h)^2}{2} - \frac{\lambda}{4} \frac{(v + h)^4}{4}\right),$$  (2.25)

where the Weinberg angle is defined by the relation $\tan \theta_W \equiv g'/g$. We also have defined the mediator fields of the charged weak interactions $W^{\pm}_\mu$,

$$W^{\pm}_\mu = (W^{1}_\mu \pm i W^{2}_\mu)/\sqrt{2}.$$

These physical fields $W^{\pm}_\mu$ acquire mass equivalent to $M_W = gv/2 = ev/2 \sin \theta_W$ and the field that mediates the neutral weak interactions $Z_\mu$,

$$Z_\mu = W^{3}_\mu \cos \theta_W - B_\mu \sin \theta_W,$$

acquires a mass $M_Z = \sqrt{g^2 + g'^2}/2 = M_W/ \cos \theta_W$. The photon field is written as the orthogonal neutral combination

$$A_\mu = B_\mu \cos \theta_W + W^{3}_\mu \sin \theta_W,$$

and its mass is $M_A = 0$, leaving the $U(1)_{EM}$ unbroken. There are also Yukawa interactions between the Higgs doublet $\Phi$ with the quarks and leptons, that can be written as

$$\mathcal{L}_{\Phi F} = \mathcal{L}_{Y \text{(quarks)}} + \mathcal{L}_{Y \text{(leptons)}},$$  (2.29)

where

$$\mathcal{L}_{Y \text{(quarks)}} = - \sum_{i,j=1}^{3} \left[ G_{ij}^u \bar{R}_u^i \left( \Phi^d L^j_q \right) + G_{ij}^d \bar{R}_d^i \left( \Phi^u L^j_q \right) + h.c. \right],$$  (2.30)
\[ \mathcal{L}_{Y(\text{leptons})} = - \sum_{i,j=1}^{3} \left[ G_{i,j}^\ell (\mathbf{U}_i^\ell \Phi) R_j^\ell + \text{h.c.} \right], \quad (2.31) \]

where \( G_{ij}^u, G_{ij}^d \) and \( G_{ij}^\ell \) are the Yukawa couplings, these are not diagonal in the generation indexes nor real, and \( \Phi \equiv i \sigma_2 \Phi^* \). We note that all these terms are also gauge invariant under \( SU(2)_L \) and have zero net hypercharge \( Y \).

In the following we will consider \( \mathcal{L}_{Y(\text{quarks})} \) in (2.30), and after replacing \( \phi \) (2.24) in (2.30), we can identify

\[ -\bar{u}_i^L M_{ij}^u u_j^L + \text{h.c.}, \quad (2.32) \]

where \( u_j^L \) is the left-handed up-type quark of the doublet \( L^j_q \) (2.7) and \( \bar{u}_R = \{ \bar{u}_R, \bar{c}_R, \bar{t}_R \} \).

To the down-type quarks we have also

\[ -\bar{d}_i^L M_{ij}^d d_j^L + \text{h.c.}, \quad (2.33) \]

where \( d_j^L \) is the left-handed down-type quark of the doublet \( L^j_q \) (2.7) and \( \bar{d}_R = \{ \bar{d}_R, \bar{s}_R, \bar{b}_R \} \).

The matrices \( M^u \) and \( M^d \), which are generally not diagonal, are given by \( M_{ij}^{u(d)} = G_{ij}^{u(d)} v / \sqrt{2} \). To diagonalize these mass matrices, the unitary matrices \( U(D)_{L,R} \) are defined such as:

\[ u_i^L = U_{ij}^L u_j^L, \quad d_i^L = D_{ij}^L d_j^L, \quad (2.34) \]

\[ u_i^R = U_{ij}^R u_j^R, \quad d_i^R = D_{ij}^R d_j^R, \quad (2.35) \]

Note that the gauge eigenstates \( (q) \) are linear combinations of the mass eigenstates \( (q') \), so we have to do the basis changes given by (2.34) and (2.35) to diagonalize \( M^U \) and \( M^D \), as follows

\[ M^U_{\text{diag}} \equiv U_R^\dagger M^U U_L = \begin{pmatrix} m_u & 0 & 0 \\ 0 & m_e & 0 \\ 0 & 0 & m_t \end{pmatrix}, \quad (2.36) \]

\[ M^D_{\text{diag}} \equiv D_R^\dagger M^D D_L = \begin{pmatrix} m_d & 0 & 0 \\ 0 & m_s & 0 \\ 0 & 0 & m_b \end{pmatrix}. \quad (2.37) \]

Considering the quark sector in (2.29) after the EW symmetry breaking, we need to go to the mass basis to diagonalize the Yukawa terms in (2.30). This is done with the \( U_{L,R}, D_{L,R} \) unitary transformations.
2.2 Electroweak Model

For the case of charged current $J_{W}^{+}$, we have that it must be proportional to

$$
\left( \bar{u}' \ c' \ \bar{t}' \right)_{L} U_{L}^{\dagger} \gamma_{\mu} \ D_{L} \left( \begin{array}{c}
\frac{d'}{b'}
\end{array} \right)_{L}.
$$

(2.38)

That is, the charged current coupling will not be diagonal anymore, since $U_{L}^{\dagger}D_{L} \neq 1_{3}$. This unitary matrix that express the mixing between the quarks is known as Cabibbo-Kobayashi-Maskawa (CKM) matrix

$$
V_{\text{CKM}} \equiv U_{L}^{\dagger}D_{L} = \left( \begin{array}{ccc}
V_{ud} & V_{us} & V_{ub} \\
V_{cd} & V_{cs} & V_{cb} \\
V_{td} & V_{ts} & V_{tb}
\end{array} \right).
$$

(2.39)

In the case of neutral current $J_{Z}$, considering up-type SM quarks, it must be proportional to

$$
\left( \bar{u}' \ c' \ \bar{t}' \right)_{L,R} U_{L,R}^{\dagger} \gamma_{\mu} U_{L,R} \left( \begin{array}{c}
\frac{u'}{c'} \ \frac{t'}{t'}
\end{array} \right)_{L,R}.
$$

(2.40)

So there is no mixing of the quarks in the sector of neutral currents, due to the fact that $U_{L}$ and $U_{R}$ are unitary, namely, the couplings are diagonal. Thus, in the Standard Model there are no interactions that change flavor in neutral currents, at least at tree level.

Now we will consider $\mathcal{L}_{Y(\text{leptons})}$, jointly with $\phi$ in (2.24), we can obtain mass terms

$$
-\bar{e}^{i} L_{i,j} e^{j}_{R} + \text{h.c.},
$$

(2.41)

where $e^{i}_{L,R} = \{ e_{L,R}, \mu_{L,R}, \tau_{L,R} \}$ and we identify from (2.31) that the charged lepton mass matrix is given by $M_{i,j}^{\ell} = G_{i,j}^{\ell} v/\sqrt{2}$.

To diagonalize $M_{i,j}^{\ell}$, the matrices $U_{\ell}$ and $W_{\ell}$ are defined as

$$
e^{i}_{L} = U_{\ell}^{i,j} e^{j}_{L}, \quad e^{i}_{R} = W_{\ell}^{i,j} e^{j}_{R}.
$$

(2.42)

Then these basis changes yield the diagonal lepton mass matrix

$$
M_{\text{diag}}^{\ell} \equiv D_{R}^{\dagger} M^{D} D_{L} = \left( \begin{array}{ccc}
m_{e} & 0 & 0 \\
0 & m_{\mu} & 0 \\
0 & 0 & m_{\tau}
\end{array} \right).
$$

(2.43)

With this procedure it is possible to obtain the masses terms to the leptons. However, the value of $M_{\ell}$ is not predicted by the theory since the Yukawa couplings $G_{i,j}^{\ell}$ were introduced arbitrarily to reproduce the masses of the observed leptons. Just as in the quark case, the theory does not provide the values of $M_{i,j}^{u(d)}$. That
is, the Yukawa couplings $G_u^{(d)}$ were arbitrarily introduced to correctly give the masses of the fermions observed, once they are diagonalized.

## 2.3 Motivation of Physics Beyond the SM

In the previous sections we saw that the SM of elementary particles offers a theoretical explanation for the interactions of all elementary particles we know of today. It is extremely successful when compared with the experimental data we have nowadays. As examples, we have the detection of neutral currents in the decade of 70s, the predictions made to the bosons mass $W^\pm$ and $Z$, experiments made in LEPI, LEPII and the Tevatron [18, 19] with high precision ($\lesssim 1\%$).

The model needs a scalar particle remaining form the process of spontaneous symmetry breaking in the electroweak sector, the Higgs boson that couples with the other particles of the SM and that recently has been discovered at the LHC [1, 2].

Despite the success of the SM, it has deficiencies in how to explain the hierarchy problem and the hierarchy of the SM fermion masses among many others. The hierarchy problem is related to the quantum instability of the vacuum that sets the electroweak scale around $m_{EW} \sim 250 GeV$. In addition, the SM does not include the interaction with gravity, which is non-renormalizable and can be ignored up to scales of order of Planck mass.

### 2.3.1 The Gauge Hierarchy Problem

Despite the success of the SM when compared with experiment [3, 4] we have quite important reasons to believe that the SM is not complete, besides the fact that gravity is not included. Among all these, the one that requires new physics not too far above the TeV scale is the hierarchy problem. The SM does not provide a satisfactory explanation to the hierarchy problem [5, 6]. This problem can be understood when we calculate the quantum corrections to the Higgs mass. For instance, the largest of these corrections comes from the virtual top pair contribution up to 1 loop to the Higgs propagator as in Figure (2.1). This contribution is given by
2.3 Motivation of Physics Beyond the SM

\[ -i\delta m_h^2 = -N_c \left( \frac{\lambda_t}{\sqrt{2}} \right)^2 \int \frac{d^4 p}{(2\pi)^4} \text{Tr} \left[ \left( \frac{\not{p} + m_t}{p^2 - m_t^2} \right) \left( \frac{\not{p} + m_t}{p^2 - m_t^2} \right) \right] \]

\[ = -2N_c \lambda_t^2 \int \frac{d^4 p}{(2\pi)^4} \left( p^2 + m_t^2 \right) \left( p^2 - m_t^2 \right) \]  

(2.44)

Using a Wick rotation, i.e., \( p_0 \to ip_4, \ p^2 \to -p_E^2 \), jointly with the angular integration, we obtain

\[ \delta m_h^2 = -\frac{N_c \lambda_t^2}{8\pi^2} \int_{0}^{\Lambda_{UV}^2} dp_E^2 \frac{p_E^2(p_E^2 - m_t^2)}{(p_E^2 + m_t^2)^2} \]

\[ = -\frac{N_c \lambda_t^2}{8\pi^2} \left[ \Lambda_{UV}^2 + ... \right] \]  

(2.45)

where \( N_c = 3 \), and \( \Lambda_{UV} \) is the highest energy where we believe the SM can be used for this computation. For instance, if we consider \( \Lambda_{UV} = M_{\text{Planck}} \), the scale where gravity becomes strong and needs to be included,

\[ M_{\text{Planck}} = \left( \frac{\hbar c}{G_{\text{Newton}}} \right)^{1/2} \simeq 1.2 \times 10^{19} \text{ GeV} \]  

(2.46)

where in this scale the quantum gravitational effects will become important. On the other hand, the recent discovery of a new particle at the Large Hadron Collider (LHC) \([1, 2]\) confirms that this particle is like the Higgs boson of the SM with mass \( m_h \approx 125 \text{ GeV} \), when the electroweak symmetry is broken by the VEV of scalar Higgs.

So, as shown in (2.45), this correction to the Higgs mass squared has quadratic sensitivity to the cutoff of the theory, and then, if the SM is valid until the Planck scale, we will need a large fine tuning to obtain the observed Higgs mass in the electroweak scale. This fine tuning is not natural and needs new physics beyond the SM to restore naturalness \([5]\). That is not the case for the masses associated to other SM elementary particles, for instance, considering a light fermion or a
gauge boson as can be found in Ref. [20], as we see below.

Let us consider the quantum corrections to the self-energy of the electron as an example, as shown in Figure (2.2). We will compute this correction at zero external momentum, considering the one-loop diagram of the electron propagator that comes from the $\gamma$ boson contribution, this result in a contribution given by

$$\delta m_{e\gamma} = m_e e^2 \frac{1}{2\pi^2} \int_0^\Lambda dp_E \frac{p_E^3}{(p_E^2)(p_E^2 + m_e^2)}$$

$$= m_e e^2 \frac{1}{4\pi^2} \ln \left( \frac{\Lambda^2 + m_e^2}{m_e^2} \right). \quad (2.47)$$

Consequently, from the loop considered to determine $\delta m_e$, we can see that this is divergent but only logarithmically sensitive to the cutoff of the theory. If, for instance, we use $\Lambda_{UV} = M_{Planck}$ we have

$$\delta m_e = 0.3m_e, \quad (2.48)$$

which is not that large. It is also a multiplicative shift, a reflection of chiral symmetry.

Similarly to the previous calculations, we illustrate the quantum correction at one-loop of the W self energy, at external zero momentum. For instance, considering the contributions as indicated in Figure (2.3).
The corresponding contribution to the $\delta m^2_W$ after a Wick rotation and the angular integration associated with the first diagram in Figure (2.3) is given by

\[
\delta m^2_{Wa} = N_c g^2 m_t m_b \frac{1}{8\pi^2} \int_0^A dp_E \left( \frac{p_E^3}{(p_E^2 + m_t^2)(p_E^2 + m_b^2)} \right)
\]

\[
= \frac{N_c g^2 m_t m_b}{16\pi^2(m_t^2 - m_b^2)} \left[ m_t^2 \ln \left( \frac{A^2 + m_t^2}{m_t^2} \right) - m_b^2 \ln \left( \frac{A^2 + m_b^2}{m_b^2} \right) \right]
\]

where $N_c = 3$ due that we deal with three colors of quarks.

Now, from the diagram in Figure (2.2b) gives a contribution to the $\delta m^2_W$ given by

\[
\delta m^2_{Wb} = g^2 m_W^2 \frac{1}{8\pi^2} \int_0^A dp_E \left( \frac{p_E^3}{(p_E^2 + m_W^2)(p_E^2 + m_h^2)} \right)
\]

\[
= \frac{g^2 m_W^2}{16\pi^2(m_W^2 - m_h^2)} \left[ m_W^2 \ln \left( \frac{A^2 + m_W^2}{m_W^2} \right) - m_h^2 \ln \left( \frac{A^2 + m_h^2}{m_h^2} \right) \right]
\]

Notice that according to (2.49) and (2.50) for the contributions considered to the $\delta m^2_W$, these contributions are also divergent but have logarithmic divergence to the cutoff. And it is possible to write these contributions as proportional to $m_W^2$. Consequently, in the massless limit of fermions as well as gauge bosons we will have the mass parameters quantum corrections go to zero and recover a chiral and EW gauge symmetry, respectively.

We conclude that the quadratically divergence takes place in the Higgs mass squared as indicated in (2.45), and its quantum correction is unnatural, it is due that in the SM there is no symmetry that protects the Higgs mass.
2.3.2 Problem of Fermion Mass Hierarchy

When we review in Section 2.2 the electroweak sector of the SM, especially when through Higgs mechanism the $\Phi$ acquired an VEV, we obtained mass terms. That is as a consequence of the Yukawa interactions given by (2.31) and (2.30), these mass terms can be identified as

$$M_f = \frac{G_f v}{\sqrt{2}},$$

(2.51)

where $G_f$ are Yukawa couplings of the fermions, and are extremely varied. For instance, we have that the coupling for the electron and the top are $G_e \sim 10^{-6}$ and $G_t \sim 1$, respectively. This is a problem, since the SM does not explain why the fermions can have masses so different, after the electroweak symmetry breaking through the Higgs mechanism.

Thus, to explain the fact that these couplings are so different it is necessary to introduce physics beyond the Standard Model. There are many other problems with the SM. The strong CP problem, origin of baryon asymmetry, dark matter, among others. We will focus on theories that address the hierarchy problem, and in particular in which the Higgs mass is protected by a symmetry similar to that protecting the pion mass in QCD, i.e, the Higgs will be a pNGB.

The hierarchy problem (and maybe the problem of the fermion mass hierarchy) seem to be a good guides to construct theories Beyond the SM. Let us consider theories that solve these hierarchy problems generating large hierarchy of scales.
CHAPTER 3

New Fermions in BSM Theories

As was pointed out in the previous chapter, the SM does not provide a satisfactory explanation for the hierarchy problem. Extensions of the SM that solve the hierarchy problem without supersymmetry \cite{21} require the presence of new states partners of the SM fields under some symmetry. In particular there will be partners of fermions, especially of the top quark, of gauge bosons, etc. We will focus here on the Vector-like quarks that are partners of the SM fermions. Several theories have been suggested in the literature, for instance Little Higgs models \cite{15, 22}, composite Higgs models \cite{23, 24, 25} and quiver theories \cite{8, 10}.

As a first example, we will study how the hierarchy problem is addressed in a Little Higgs model \cite{15, 26}. Firstly, we consider two independent $SU(3)$ global symmetries, with two nonlinear sigma fields that parametrize the spontaneous symmetry breaking associated with the coset $[SU(3)/SU(2)]^2$ and are given by

\[
\phi_1 = \exp \left\{ \frac{i}{f} \begin{pmatrix} 0 & 0 & k_1 \\ 0 & 0 & k_2 \\ k_1^* & k_2^* & 0 \end{pmatrix} \right\} \exp \left\{ \frac{i}{f} \begin{pmatrix} 0 & 0 & H_1 \\ 0 & 0 & H_2 \\ H_1^* & H_2^* & 0 \end{pmatrix} \right\} \begin{pmatrix} 0 \\ 0 \\ f \end{pmatrix}, \tag{3.1}
\]

\[
\phi_2 = \exp \left\{ \frac{i}{f} \begin{pmatrix} 0 & 0 & k_1 \\ 0 & 0 & k_2 \\ k_1^* & k_2^* & 0 \end{pmatrix} \right\} \exp \left\{ \frac{-i}{f} \begin{pmatrix} 0 & 0 & H_1 \\ 0 & 0 & H_2 \\ H_1^* & H_2^* & 0 \end{pmatrix} \right\} \begin{pmatrix} 0 \\ 0 \\ f \end{pmatrix}, \tag{3.2}
\]

where $H_1, H_2, k_1$ and $K_2$ are complex fields, with the same symmetry breaking scale given by $f$. The symmetry breaking pattern is the coset $[SU(3)/SU(2)]^2$, therefore, after the breaking symmetry of the two $SU(3)$ we will identify 10 spontaneously broken generators, resulting in 10 NGBs. Notice that two singlet
fields of $SU(2)$ were ignored for simplicity in the parametrization of both scalar fields $\phi_1$ and $\phi_2$. Then, we add the interaction between the scalar fields and gauge bosons associated with the $SU(3)$ through the covariant derivatives acting on $\phi_1$ and $\phi_2$. We write the Lagrangian $\mathcal{L}$ associated with these fields as follows

$$\mathcal{L} = (D^\mu \phi_1)^\dagger (D_\mu \phi_1) + (D^\mu \phi_2)^\dagger (D_\mu \phi_2),$$  \hspace{1cm} (3.3)$$

where

$$D_\mu = \partial_\mu - ig A_\mu^a T^a,$$  \hspace{1cm} (3.4)$$

such that $T^a$ are the $SU(3)$ generators with $a = 1, 2, \ldots, 8$. We can identify the interactions between the scalar fields and the gauge bosons by expanding the kinetic terms in (3.3),

$$\begin{align*}
&D^\mu \phi_i)^\dagger (D_\mu \phi_i) = (\partial_\mu \phi_j)^\dagger (\partial^\mu \phi_j) + g \left[ i \phi_i^\dagger A_\mu^a T^a \partial^\mu \phi_i + \text{h.c.} \right] \\
&\quad + g^2 \left[ \phi_i^\dagger A_\mu^a A_\nu^b T^b T^a \phi_i \right].
\end{align*}$$  \hspace{1cm} (3.5)$$

Figure 3.1. Quantum corrections at one-loop for two-point function of the scalar fields $\phi_i$ due to the $SU(3)$ gauge interaction.

In the calculation of the quantum contribution from Figure (3.1a) the Feynman gauge will be used. This gives

$$i \Sigma_{(a)} = \int \frac{d^4 k}{(2\pi)^4} \left[ i g^2 g^a T^r_{i j} T^s_{j m} \right] \left( \frac{-ig_{\mu \nu} \delta^r s}{k^2} \right),$$  \hspace{1cm} (3.6)$$

$$= -8ig^2 \left( T^r_{i j} T^s_{j m} \right) \frac{1}{16\pi^2} A^2.$$  \hspace{1cm} (3.6)$$

from Figure (3.1b), we also have

$$i \Sigma_{(b)} = \int \frac{d^4 k}{(2\pi)^4} \left( ig k^a T^r_{i j} \right) \left( i \delta^j a \right) \left( ig k^a T^a_{i m} \right) \left( \frac{-ig_{\mu \nu} \delta^r s}{k^2} \right),$$  \hspace{1cm} (3.7)$$

$$= ig^2 \left( T^r_{i j} T^s_{j m} \right) \frac{1}{16\pi^2} A^2.$$  \hspace{1cm} (3.7)$$
So the contributions potential
\[ \propto \frac{g^4}{16\pi^2} A^2 \left( \phi_1 \phi_1 + \phi_2 \phi_2 \right), \quad (3.8) \]

and then substituting (3.1), (3.2) in (3.8) we will obtain a constant term that that does not contribute to the potential for $H$, since (3.8) does not depend on the Higgs.

![Figure 3.2. Quantum correction at one-loop from the interaction terms of two gauge boson and two scalars included in (3.3).](image)

Now, we consider the quantum correction from Figure (3.2) we can write the Feynman integral by considering a power counting
\[ i \Sigma_4 \propto \int \frac{d^4k}{(2\pi)^4} \times \left( \frac{g^2}{k^2} \right)^2 \left( \frac{g^2}{k^2} \right)^2, \quad (3.9) \]

which results in
\[ = \frac{g^4}{16\pi^2} \ln \left( \frac{A^2}{\mu^2} \right), \quad (3.10) \]

the following operator that does not have a quadratic divergence
\[ \frac{g^4}{16\pi^2} \ln \left( \frac{A^2}{\mu^2} \right) |\phi_1 \phi_2|^2. \quad (3.11) \]

To identify the coefficient of $H^\dagger H$, i.e., its mass squared we will substitute the parameterizations (3.1), (3.2) in (3.11), for this purpose we compute
\[ \phi_1 \phi_2 = \begin{pmatrix} 0 & f \end{pmatrix} \exp \left\{ -\frac{2i}{f} \begin{pmatrix} 0 & H \\ H^\dagger & 0 \end{pmatrix} \right\} \begin{pmatrix} 0 \\ f \end{pmatrix}, \quad (3.12) \]

after expanding the exponential matrix up to order of $\frac{1}{f^2}$ we have
\[ \phi_1^\dagger \phi_2 = \begin{pmatrix} 0 & f \end{pmatrix} \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} - \frac{2i}{f} \begin{pmatrix} 0 & H \\ H^\dagger & 0 \end{pmatrix} \]
\[ - \frac{2}{f^2} \begin{pmatrix} HH^\dagger & 0 \\ 0 & H^\dagger H \end{pmatrix} + \mathcal{O} \left( \frac{1}{f^3} \right) \begin{pmatrix} 0 \\ f \end{pmatrix} \]
\[ = f^2 - 2H^\dagger H + \cdots \] (3.13)
we can substitute this result in (3.11), obtaining a mass term
\[ - \frac{g^2 f^2}{4\pi^2} \ln \left( \frac{A^2}{\mu^2} \right) H^\dagger H. \] (3.14)
Thus we have a theory that does not have quadratic divergence at one-loop for the mass of \( H \), and it is the pseudo-Nambu Goldstone Boson associated with two scalar fields that break separately each \( SU(3) \) to \( SU(2) \). The fact that to generate a genuine contribution to the Higgs potential we need the contributions of both \( \phi_1 \) and \( \phi_2 \) is an example of the so-called collective breaking. Notice that the term given in (3.11) explicitly breaks both \( SU(3) \) to the diagonal.

There is a similar mechanism for the Yukawa contributions to the potential. The \( \phi_1 \) and \( \phi_2 \) Yukawas are
\[ \mathcal{L} = -\lambda_1 \bar{t}_1 R \phi_1^\dagger \Psi_L - \lambda_2 \bar{t}_2 R \phi_2^\dagger \Psi_L + \text{h.c.}, \] (3.15)
where \( \Psi_L \) is a \( SU(3) \) triplet given by
\[ \Psi_L = \begin{pmatrix} t \\ b \\ T \end{pmatrix}_L, \] (3.16)
and taking into account the \( SU(2) \) doublet
\[ Q_L = \begin{pmatrix} t \\ b \end{pmatrix}_L, \] (3.17)
jointly with
\[ H = \begin{pmatrix} H_1 \\ H_2 \end{pmatrix}. \] (3.18)
Now, we can substitute (3.1), (3.2) in (3.15) and using the rotation where $k_1$ and $k_2$ are removed, i.e., in unitary gauge for $SU(3)$ jointly with (3.17), we have

\[-\lambda_1 \bar{t}_{1R} \left[ \exp \left\{ \frac{i}{f} \begin{pmatrix} 0 & H \\ H^\dagger & 0 \end{pmatrix} \right\} \begin{pmatrix} 0 \\ f \end{pmatrix} \right]^\dagger \begin{pmatrix} Q \\ T \end{pmatrix}_L,\]

\[-\lambda_2 \bar{t}_{2R} \left[ \exp \left\{ -\frac{i}{f} \begin{pmatrix} 0 & H \\ H^\dagger & 0 \end{pmatrix} \right\} \begin{pmatrix} 0 \\ f \end{pmatrix} \right]^\dagger \begin{pmatrix} Q \\ T \end{pmatrix}_L, \tag{3.19}\]

expanding the exponential matrix functions up to order of \(\frac{1}{f^2}\)

\[-\lambda_1 \bar{t}_{1R} \begin{pmatrix} 0 \\ f \end{pmatrix} \left[ 1 \right. - \frac{i}{f} \begin{pmatrix} 0 & H \\ H^\dagger & 0 \end{pmatrix} - \frac{1}{2f^2} \begin{pmatrix} HH^\dagger & 0 \\ 0 & HH^\dagger \end{pmatrix} \right] \begin{pmatrix} Q \\ T \end{pmatrix}_L,\]

\[-\lambda_2 \bar{t}_{2R} \begin{pmatrix} 0 \\ f \end{pmatrix} \left[ 1 \right. + \frac{i}{f} \begin{pmatrix} 0 & H \\ H^\dagger & 0 \end{pmatrix} - \frac{1}{2f^2} \begin{pmatrix} HH^\dagger & 0 \\ 0 & HH^\dagger \end{pmatrix} \right] \begin{pmatrix} Q \\ T \end{pmatrix}_L, \tag{3.20}\]

and considering

\[\lambda_1 = \lambda_2 = \frac{\lambda}{\sqrt{2}} \tag{3.21}\]

the terms given in (3.20) are simplified to

\[-\frac{\lambda}{\sqrt{2}} \left[ f (\bar{t}_{1R} + \bar{t}_{2R}) T_L + i (\bar{t}_{2R} - \bar{t}_{1R}) H^\dagger Q_L - \frac{1}{2f} (\bar{t}_{2R} + \bar{t}_{1R}) H^\dagger HT_L + \ldots + \text{h.c.} \right], \tag{3.22}\]

now, writing the following combinations

\[T_R = \bar{t}_{1R} + \bar{t}_{2R} \tag{3.23}\]

\[\bar{t}_R = \frac{i}{\sqrt{2}} (\bar{t}_{2R} - \bar{t}_{1R}) \tag{3.24}\]

substituting these combinations, we rewrite (3.22) as

\[-\lambda \left[ f T_R T_L + \bar{t}_R H^\dagger Q_L - \frac{1}{2f} T_R H^\dagger HT_L + \ldots + \text{h.c.} \right], \tag{3.25}\]
where as in Ref. [26], here $H$ can be identified as

$$H = \frac{1}{\sqrt{2}} \left( h - i\varphi_3 \right),$$  \hspace{1cm} (3.26)

expanding about the symmetric point, $\langle h \rangle = 0$, we identify from (3.25) the following terms

$$-\lambda f \bar{T}_R T_L - \frac{\lambda}{\sqrt{2}} \bar{t}_R t_L h + \frac{\lambda}{4f} \bar{T}_R T_L h^2 + ... + \text{h.c.}$$  \hspace{1cm} (3.27)

From these, we can compute the corrections to the Higgs mass squared up to 1 loop, these quantum corrections to the Higgs propagator are shown in Figure (3.3).

The contribution to the Higgs mass squared from Figure (3.3a) is given by

$$\delta m^2_{h(a)} = -N_c \lambda^2 \frac{1}{4\pi^2} \int_0^A dE \frac{p^3_E}{p^4_E}$$

$$= -\frac{N_c}{8\pi^2} \lambda^2 A^2,$$  \hspace{1cm} (3.28)

and from Figure (3.3b), we also have

$$\delta m^2_{h(b)} = N_c \lambda^2 \frac{1}{4\pi^2} \int_0^A dE \frac{p^3_E}{p^4_E}$$

$$= \frac{N_c}{8\pi^2} \lambda^2 A^2.$$  \hspace{1cm} (3.29)
Thus the quadratic divergent contributions to the Higgs mass (3.28) and (3.29) are canceled by the addition of the quantum corrections at one-loop from the top and $T$. And also we saw that the model involves three scales $\Lambda$, $f$ and $M_{\text{weak}} \sim$ such that its squared is given by the mass term in (3.14), where $\Lambda \lesssim 4\pi f$ as in Ref. [15], this could be obtained by doing a naive dimensional analysis after expanding the kinetic term of the scalar fields (3.1), (3.2). The size of $f$ is of order to the TeV scale if $g$ is equal to the $SU(2)$ gauge coupling. Thus, it is important to study theories where we will have fermion masses that are in the TeV scale to solve the hierarchy problem through to the cancellation of the quadratic divergence as above. This was an example of theories where a Vector-like quark must be present to solve the hierarchy problem. In the next sections we will introduce another example where the fermion masses can be in the TeV scale.

### 3.1 Quiver Theories

This section has attempted to provide a brief summary of the literature relating to quiver theories [7, 8, 10], because these are another possibility to address the hierarchy problem and the fermion mass hierarchies, in similar way to AdS$_5$ theories [5] [13] [14]. To study the more important phenomenology associated with the excited SM particles as studied in Ref. [10], we need to compute the couplings involved by obtaining their wave functions as we will see below.

In the quiver theories approach we consider a four dimensional (4D) gauge theory associated with a product gauge group

$$G = G_0 \times G_1 \times \ldots \times G_{N-1} \times G_N.$$  \hspace{1cm} (3.30)

Here, we will consider that $G_j = SU(n)_j$ is a gauge symmetry, where $j = 0, 1, \ldots, N$. In addition to this framework, we include a set of scalar link fields $\Phi_j$, with $j = 1, \ldots, N$, such that $\Phi_j$ transforms under the bi-fundamental representation of groups $G_{j-1} \times G_j$, as follows:

$$\Phi_j \rightarrow U_{j-1} \Phi_j U_j^\dagger.$$  \hspace{1cm} (3.31)

The action with the considerations mentioned above is given by

$$S = \int d^4x \left\{ \sum_{j=0}^N \frac{1}{2} \Tr \left[ F_{\mu\nu}^j F^{j\mu\nu} \right] + \sum_{j=1}^N \Tr \left[ (D_\mu \Phi_j)^\dagger (D^\mu \Phi_j) \right] - V(\Phi_j) \right\},$$  \hspace{1cm} (3.32)
where \( F_{\mu\nu}^j = F_{\mu\nu}^a T_j^a \) is the gauge field strength tensor. Here \( T_j^a \) are the generators of the symmetry group \( SU(n)_j \) and \( F_{\mu\nu}^a \) is more explicitly given by

\[
F_{\mu\nu}^a = \partial_\mu A_\nu^a - \partial_\nu A_\mu^a + g_j f_{abc} A_\mu^b A_\nu^c, \tag{3.33}
\]

where \( f_{abc} \) are related through the commutation relations \( [T_j^a, T_j^b] = if_{abc} T_j^c \).

The covariant derivative \( D_\mu \Phi_j \) is given by

\[
D_\mu \Phi_j = \partial_\mu \Phi_j + ig_j A_\mu^a \Phi_j - ig_j A_{\mu, j}^a \Phi_j - ig_j \Phi_j A_{\mu, j}^a T_j^a. \tag{3.34}
\]

In addition, we assume that the \( \Phi_j \)'s develop a diagonal VEV, such that \( SU(n)_{j-1} \times SU(n)_j \) is broken down to the diagonal group. This means that for each VEV we have to have \( n^2 - 1 \) Nambu-Goldstone Bosons (NGBs) and we can use the parameterization of the non-linear sigma models for the \( \Phi_j \)'s given by

\[
\Phi_j = v_j e^{i\pi_j^a \hat{T}_j^a / v_j}, \tag{3.35}
\]

where the broken generators are \( \hat{T}_j^a \)'s, the NGBs are \( \pi_j^a \) and the \( \Phi_j \)'s VEVs \( v_j \) are related with the breaking of \( SU(n)_{j-1} \times SU(n)_j \). The model can be schematically represented by Figure (3.4). We choose to parametrize the \( v_j \)'s as

\[
v_j = v q^j, \tag{3.36}
\]

with \( 0 < q < 1 \), such that \( v \) is the UV mass scale and then we have that the \( v_j \)'s decrease as follow \( v_1 > v_j > v_N \). These choices have been studied in [7, 8, 9, 10]. In this example we can consider that each gauge coupling satisfies

\[
g_0 = g_1 = ... g_N = g, \tag{3.37}
\]

and as we have indicated that all gauge groups are identical \( T_j^a = T_{j-1}^a = T^a \), with \( j = 1, \ldots, N \). The action (3.32) can be represented by the bosonic quiver diagram of Figure (3.4), where the circles represent the gauge group’s \( G_j \), \( j = 0, 1, \ldots, N \). Here \( j \) is identified with the index of the site in the quiver diagram, henceforth we will call \( j \) as site index. To expand the kinetic term of the \( \Phi_j \)'s in (3.32), we need to use (3.35). we obtain

![Figure 3.4: Quiver diagram associated with the theory in (3.32).](image-url)
3.1 Quiver Theories

\[
\text{Tr } [(D_\mu \Phi_j) \dagger (D^\mu \Phi_j)] = \text{Tr } [(\partial_\mu \Phi_j) \dagger (\partial^\mu \Phi_j)] + g \text{Tr } [i(\partial_\mu \Phi_j) \dagger (A_\mu^{\mu} \Phi_j - \Phi_j A_\mu)] + \text{h.c.}
\]

\[
+ v_j^2 g^2 \text{Tr } [A_{\mu,j-1} A_{\mu,j}^{\mu}] - 2g^2 \text{Tr } \left[ \Phi_j A_{\mu,j-1} A_{\mu,j}^{\mu} \right] \\
+ v_j^2 g^2 \text{Tr } [A_{\mu,j} A_{\mu,j}^{\mu}] .
\]  (3.38)

After that, we replace (3.35) in (3.38), using the normalization \( \text{Tr } [T^a T^b] = \frac{1}{2} \delta^{ab} \), such that we consider only quadratic terms in the fields \( \pi^a_j \) and \( A_{\mu,j}^a \). Thus we have

\[
\sum_{j=1}^N \text{Tr } [(D_\mu \Phi_j) \dagger (D^\mu \Phi_j)] = \sum_{j=1}^N \left[ \frac{1}{2} (\partial_\mu \pi^a_j)^2 - v_j g \partial_\mu \pi^a_j (A^{\mu, a}_j - A^{\mu, a}_{j-1}) + \frac{1}{2} v_j^2 g^2 (A_{\mu,j-1}^a)^2 \\
- v_j^2 g^2 A_{\mu,j-1, \mu}^a + \frac{1}{2} v_j^2 g^2 (A_{\mu,j-1}^a)^2 \right] \\
= \sum_{j=1}^N \frac{1}{2} [\partial_\mu \pi^a_j - v_j g (A^{\mu, a}_j - A^{\mu, a}_{j-1})]^2 .
\]  (3.39)

As we can see, (3.39) includes the cross term mixing the NGBs with the gauge bosons in (3.32). To cancel these quadratic terms of the form \( \partial_\mu \pi^a_j (A^{\mu, a}_j - A^{\mu, a}_{j-1}) \), we chose to introduce the gauge-fixing term

\[
\mathcal{L}_{GF} = -\frac{1}{2\xi} \sum_{j=0}^{N} [\partial_\mu A^{\mu, a}_j + \xi g (v_j \pi^a_j - v_{j+1} \pi^a_{j+1})]^2 ,
\]  (3.40)

where \( \xi \) is the gauge parameter, and we considered that \( \xi \) is the same site for all sites. Then (3.40) can be written as

\[
\mathcal{L}_{GF} = -\frac{1}{2\xi} \sum_{j=0}^{N} (\partial_\mu A^{\mu, a}_j)^2 + \sum_{j=0}^{N} g A^{\mu, a}_j (v_j \partial_\mu \pi^a_j - v_{j+1} \partial_\mu \pi^a_{j+1}) \\
- \frac{1}{2} \sum_{j=0}^{N} \xi [g (v_j \pi^a_j - v_{j+1} \pi^a_{j+1})]^2 ,
\]  (3.41)

where the second term was integrated by parts. This can be rewritten as follows

\[
\mathcal{L}_{GF} = -\frac{1}{2\xi} \sum_{j=0}^{N} (\partial_\mu A^{\mu, a}_j)^2 + \sum_{j=1}^{N} g v_j \partial_\mu \pi^a_j (A^{\mu, a}_j - A^{\mu, a}_{j-1}) \\
- \frac{1}{2} \sum_{j=0}^{N} \xi [g (v_j \pi^a_j - v_{j+1} \pi^a_{j+1})]^2 .
\]  (3.42)
Thus the action (3.32), using (3.39), with the inclusion of the gauge-fixing term in the form of (3.42) is given by

\[ S = \int d^4x \left\{ -\sum_{j=0}^{N} \left[ \frac{1}{4}(F^a_{\mu\nu})^2 + \frac{1}{2\xi}(\partial_{\mu}A^a_{\mu})^2 \right] + \frac{1}{2} \sum_{j=1}^{N} (\partial_{\mu}\pi^a_j)^2 \right\} \]

\[-\frac{1}{2} \sum_{j=1}^{N-1} \xi [g(v_j\pi^a_j - v_{j+1}\pi^a_{j+1})]^2 - \frac{1}{2} \xi g^2 v_1^2(\pi^a_1)^2 - \frac{1}{2} \xi g^2 v_N^2(\pi^a_N)^2 \]

\[+ \frac{1}{2} \sum_{j=1}^{N} v_j^2 g^2(A^a_{\mu} - A^{a}_{\mu - 1})^2 \} \]  

(3.43)

Notice that this action includes the mass terms of NGBs and gauge bosons. The mass term for the NGBs in the Lagrangian associated with the action (3.43) is given by

\[ L_{M_a} = -\frac{1}{2} \sum_{j=1}^{N-1} \xi [g(v_j\pi^a_j - v_{j+1}\pi^a_{j+1})]^2 - \frac{1}{2} \xi g^2 v_1^2(\pi^a_1)^2 - \frac{1}{2} \xi g^2 v_N^2(\pi^a_N)^2 \equiv -\frac{1}{2} \pi^{aT} M^2_\pi \pi^a, \]

(3.44)

where \( \pi^{aT} \) was written in the basis \( \pi^{aT} = (\pi^a_1, \pi^a_2, \ldots, \pi^a_N) \). To write the mass matrix \( M^2_\pi \) for the NGBs, we used the parametrization (3.36), obtaining

\[ M^2_\pi = g^2 v^2 \xi \begin{pmatrix}
2q^2 & -q^3 & 0 & \ldots & 0 & 0 \\
-q^3 & 2q^4 & -q^5 & \ldots & 0 & 0 \\
0 & -q^5 & 2q^6 & \ldots & 0 & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & 0 & \ldots & 2q^{2(N-1)} & -q^{2N} \\
0 & 0 & 0 & \ldots & -q^{2N} & 2q^{2N}
\end{pmatrix}. \]

(3.45)

The determinant of \( M^2_\pi \) is given by

\[ \text{Det}[M^2_\pi] = (g^2 v^2 \xi)^N (N + 1)q^{N(N+1)}. \]

(3.46)

We can see that it is different from zero. In other words, the NGBs have no zero mode in their mass eigenstate basis, such that these NGB masses are proportional to \( \sqrt{\xi} \), so by taking the limit \( \xi \rightarrow \infty \), it corresponds to the unitary gauge. In this limit the NGBs disappear from the theory. We will use this gauge, and we say that the NGBs are eaten by the gauge bosons which become massive. We will see later that it is possible to extend one of the NGBs to be the Higgs by choosing differently the boundary conditions.
To determine the spectrum of the massive gauge bosons, we consider the mass term for the gauge bosons in the Lagrangian associated with the action (3.43) that is given by

\[ L_{M_A} = \frac{1}{2} \sum_{j=1}^{N} v_j^2 g^2 (A_{j}^{\mu} a - A_{j-1}^{\mu} a)^2 \equiv -\frac{1}{2} (A_{\mu}^a)^T M_A^2 A_{\mu} a. \] (3.47)

Analogously to the case of the NGBs, \((A_{\mu}^a)^T\) was written in the basis \((A_{\mu}^a)^T = (A_{\mu,0}, A_{\mu,1}, \ldots, A_{\mu,N})\), and using the parametrization (3.36), \(M_A^2\) can be written as follows

\[
M_A^2 = g^2 v^2 \begin{pmatrix}
q^2 & -q^2 & 0 & 0 & \ldots & 0 & 0 \\
-q^2 & q^2 + q^4 & -q^4 & 0 & \ldots & 0 & 0 \\
0 & -q^4 & q^4 + q^6 & -q^6 & \ldots & 0 & 0 \\
\vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & 0 & 0 & \ldots & q^{2(N-1)} + q^2N & -q^{2N} \\
0 & 0 & 0 & 0 & \ldots & -q^{2N} & q^{2N}
\end{pmatrix}.
\] (3.48)

The spectrum of masses can be obtained by diagonalizing this matrix. For this purpose, we will define the orthonormal rotation

\[
A_{\mu,j}^a = \sum_{n=0}^{N} f_{j,n} A_{\mu}^{a (n)},
\] (3.49)

where the \(A_{\mu}^{a (n)}\) are the mass eigenstates, such that in this basis \(L_{M_A}\) can be written as

\[
L_{M_A} = \frac{1}{2} \sum_{n=0}^{N} m_{n}^2 (A_{\mu}^{a (n)})^2.
\] (3.50)

Here we perform a numerical calculation of \(f_{j,n}\) for hypothetical gauge bosons, following our previous formulation. Considering \(v \lesssim M_P = 10^{19} \text{ GeV}\) and \(v_N \approx \mathcal{O}(1) \text{ TeV}\), We show their wave-functions in Figures (3.5) and (3.6) for \(N = 4\) and \(N = 15\), respectively. In both cases, the zero mode of gauge bosons will be flat as in AdS5 theories with fields in the bulk \[13, 27\].
Figure 3.5. Gauge boson wave functions, where $j$ is a index of site and $n$ is a index of Kaluza-Klein mode. In this case $N = 4$ and some allowed $n$ are shown. For the visualization, we choose by the opposite signs of $f^{j,0}$ and $f^{j,2}$.

Figure 3.6. Gauge boson wave functions, where $j$ is a index of site and $n$ is a index of Kaluza-Klein mode. In this case $N = 15$ and some allowed $n$ are shown. For the visualization, we choose by the opposite signs of $f^{j,2}$ and $f^{j,3}$.

In order to understand better the behavior of the gauge boson wave functions, we now look at the equations they satisfy.

The coefficients $f^{j,n}$ can be obtained from the equations of motion for the fields $A^\mu_j$ by using the Lagrangian given for

$$\mathcal{L}_A = \sum_{j=0}^{N} \left\{ -\frac{1}{4} F_{\mu\nu,j} F_{\mu\nu}^{j} + \frac{g^2}{2} [v_j(A_{\mu,j-1} - A_{\mu,j})]^2 \right\}, \quad (3.51)$$
where for simplicity, the abelian case was supposed, and then we can use the Euler-Lagrange equations

$$\frac{\partial L}{\partial A_{\nu,j}} - \partial_\mu \left( \frac{\partial L}{\partial (\partial_\mu A_{\nu,j})} \right) = 0,$$

(3.52)

we obtain the following equation

$$(\partial^2 A^\nu_\mu - \partial^\nu \partial_\mu A^\mu_j) + g^2 v^2_j (A^\nu_j - A^\nu_{j-1}) + g^2 v^2_{j+1} (A^\nu_j - A^\nu_{j+1}) = 0.$$  (3.53)

Now, we will use Lorentz gauge $\partial_\mu A^\mu_j = 0$ and substituting (3.49) in (3.53) we obtain

$$f^j_n \partial^2 A^{\nu(n)}_{\nu,n} + g^2 v^2 q^2 [(1 + q^2) f^{j,n} - f^{j-1,n} - q^2 f^{j+1,n}] A^{\nu(n)} = 0.$$  (3.54)

Imposing that $A^{\nu(n)}$ satisfies the Proca equation, that is

$$\partial^2 A_{\nu,n} = -m_n^2 A_{\nu,n},$$  (3.55)

thus, we substitute (3.55) and using the definition $x^2_n \equiv m^2_n / g^2 v^2$ in (3.54), it happens that we obtain

$$[q + q^{-1} - q^{-1}(x_n q^{-j})^2] f^{j,n} - q f^{j+1,n} - q^{-1} f^{j-1,n} = 0,$$  (3.56)

jointly with the discrete Neumann boundary conditions

$$f^{0,n} = f^{-1,n}, \quad f^{N,n} = f^{N+1,n},$$  (3.57)

with the normalization condition

$$\sum_{j=0}^N (f^{j,n})^2 = 1.$$  (3.58)

We will now concentrate in the zero mode, $n = 0$ and $m_0 = 0$.

The equation (3.56) for the zero mode is

$$[q + q^{-1}] f^{0,0} - q f^{1,0} - q^{-1} f^{-1,0} = 0,$$  (3.59)

such that for $j = 0$ in (3.56), we have

$$[q + q^{-1}] f^{0,0} - q f^{1,0} - q^{-1} f^{-1,0} = 0,$$

and using (3.57) we obtain

$$f^{0,0} = f^{1,0},$$  (3.60)
iterating to the others $j'$s we have
\[ f^{0,0} = f^{1,0} = f^{2,0} = \ldots = f^{N,0}, \quad (3.61) \]

and by using the normalization condition (3.58), we obtain
\[ f_{j,0} = \frac{1}{\sqrt{N+1}}. \quad (3.62) \]

This means that the components of zero mode are equal in all sites. It is analogous to what happens in AdS$_5$ theory, where the zero modes of the gauge bosons are delocalized, as can be seen in Figures (3.5) and (3.6) for $n = 0$. For massive modes the equation (3.56) has solution as shown in Ref. [28]. For this purpose we define the following variables
\[ t[j] = x_n q^{-j}, \quad (3.63) \]
\[ F(t[j]) = q^j f^{j,n}, \quad (3.64) \]

and we substitute (3.63) and (3.64) in the equation of $q$-differences (3.56) we obtain
\[ (q + q^{-1} - q^{-1} t^2) F(t) - F(tq^{-1}) - F(tq) = 0. \quad (3.65) \]

The equation (3.65) is a special case of Hahn-Exton equation [28, 29] with solutions that are called $q$-Bessel functions. More general solutions can be written as
\[ F(t) = AJ_\nu(t; q^2) + BY_\nu(t; q^2), \quad (3.66) \]

where in general $J_\nu(t; q^2)$ and $Y_\nu(t; q^2)$ are the $q$-Bessel and $q$-Neumann functions respectively. It is interesting to examine the continuum limit $q \to 1^-$ and $N \to \infty$, as we will in the next section, we obtain the continuous ordinary functions of Bessel and Neumann [28],
\[ J_\nu(t; q) = \frac{\Gamma_q(q^{\nu+1}; q)}{\Gamma_q(q; q)} \sum_{i=0}^\infty \frac{(-1)^i q^{i(i+1)/2}}{(q^{\nu+1}; q)_i (q; q)_i} t^{2i}, \quad (3.67) \]

with the factors $(y; q)_i$ are defined as
\[ (y; q)_k = \begin{cases} 1 & \text{se } k = 0 \\ \prod_{n=0}^{k-1} (1 - y q^n) & \text{se } k \geq 1 \end{cases}, \quad (3.68) \]

for $y \in \mathbb{C}$, $i \in \mathbb{Z}_+ = \{0, 1, 2, \ldots\}$ and $(y; q)_\infty \equiv \lim_{i \to \infty} (y; q)_i$. Meanwhile
\[ Y_\nu(t; q) = \frac{\Gamma_q(\nu) \Gamma_q(1-\nu)}{\pi} q^{-\nu^2/2} \left[ \cos(\pi \nu) q^{\nu/2} J_\nu(t; q) - J_{-\nu}(t q^{-\nu/2}; q) \right], \quad (3.69) \]
where the function $\Gamma_q(\nu)$ is defined for

$$\Gamma_q(\nu) = \frac{(q;q)_\infty}{(q^\nu;q)_\infty} (1 - q)^{1-\nu}. \quad (3.70)$$

Using (3.64), (3.65) and the boundary conditions (3.57), it is possible to find the coefficients $f^{j,n}$ to within a constant $N_n$ that can be obtained from the normalization condition (3.58) as follow

$$f^{j,n} = N_n q^{-j} \left[ Y_0(x_n; q^2) J_1(x_n q^{-j}; q^2) - J_0(x_n; q^2) Y_1(x_n q^{-j}; q^2) \right]. \quad (3.71)$$

Additionally, the spectrum of masses is obtained from the equation

$$J_0(x_n; q^2) Y_0(q^{-(N+1)} x_n; q^2) - Y_0(x_n; q^2) J_0(q^{-(N+1)}; q^2) = 0. \quad (3.72)$$

In the continuum limit, when $q \to 1^-$, these coefficients (3.71) coincide to the wave functions of the excited gauge bosons in $AdS_5$ theory. Thus with the deconstruction of a 5-dimensional gauge theory it is possible to produce a correspondent quiver theory in four dimensions.

### 3.1.1 Relation to $AdS_5$

We know that the $AdS_5$ theories solve the gauge hierarchy problem, as well as the hierarchy of fermion masses. However, these theories are non renormalizable, so it is interesting to obtain a higher universe of theories that solve large hierarchies. We will start considering a continuous 5-dimensional gauge action in the Abelian case. The extension to the non-Abelian case is straightforward. Working with $AdS_5$ theories, where the extra dimension is compactified on the orbifold $S_1/Z_2$ with $-L \leq y \leq L$ and the metrics is given by

$$ds^2 = e^{-2k|y|} \eta_{\mu\nu} dx^\mu dx^\nu - dy^2, \quad (3.73)$$

where $k$ is the $AdS_5$ curvature. The action for gauge bosons is given by

$$S_A = \int d^5x \sqrt{g} \left[ -\frac{1}{4g_5^2} F_{MN} F^{MN} \right], \quad (3.74)$$

where $g_5$ is the gauge coupling in 5 dimensions, and $F_{MN} = \partial_M A_N - \partial_N A_M$ with $M = 0, 1, 2, 3$ and 5 ($y$).

The action (3.74) can be simplified to
$S_5^A = \int d^5 x \sqrt{g} \left[ -\frac{1}{4g_5^2} g^{\MO \NP} F_{\MN} F_{\OP} \right],$

\[ = \int d^4 x \int_0^L dy \sqrt{\tilde{g}} \left[ -\frac{1}{4g_5^2} e^{4ky} F_{\mu\nu} F^{\mu\nu} + \frac{1}{2g_5^2} e^{2ky} (F_{5\mu})^2 \right], \]

\[ = \int d^4 x \int_0^L dy \left[ -\frac{1}{4g_5^2} F_{\mu\nu} F^{\mu\nu} + \frac{1}{2g_5^2} e^{-2ky} \left( \partial_5 A_\mu - \partial_\mu A_5 \right)^2 \right]. \quad (3.75) \]

We will discretize the compact dimension, with spacing $\ell$. So the action (3.75) will now be

\[ S_5^A = \ell \int d^4 x \left[ \sum_{j=0}^N -\frac{1}{4g_5^2} (F_{j\mu\nu} F^{j\mu\nu}) \right. \]

\[ \left. + \sum_{j=1}^N \frac{1}{2g_5^2} e^{-2kj} \left( \frac{A_j^i - A_j^{i-1}}{\ell} - \partial_\mu A_5^j \right)^2 \right], \quad (3.76) \]

where the derivatives with respect to $y$ taken to be discretized. This action can be compared to the action from the quiver theory, To make this clear we will rescale the gauge fields as

\[ S_4^A = \int d^4 x \left[ -\sum_{j=0}^N \frac{1}{4g^2} (F_{\mu\nu,j} F^{\mu\nu}) \right. \]

\[ + \frac{1}{2} \sum_{j=1}^N \left[ \partial_\mu \pi_j + v_j (A_{\mu,j-1} - A_{\mu,j}) \right]^2 \right]. \quad (3.77) \]

We can see the equivalence of both theories setting the dictionary between discretized five-dimensional gauge theory with the purely four-dimensional gauge theory (3.77) as shown in Ref. [7]. The dictionary identifying both theories is shown in Table (3.1). In this way, we identify the sites zero and $N$ as branes UV and IR respectively.

We know that AdS$_5$ theories solve the hierarchy problem of particle physics for $kL \approx 37$ [13 30 31 32]. The continuous theory (AdS$_5$) is obtained from a quiver theory when $N \to \infty$, such that $N\ell = L$, where $L$ is the size of the extra dimension and $\ell$ is the network spacing. So we have

\[ kN\ell \sim 37. \quad (3.78) \]

Now, we will see that happens by using (3.36), the matching in Table (3.1), jointly
3.1 Quiver Theories

\[
\begin{array}{c|c}
\text{Theory with 4 dimensions} & \text{Theory with 5 dimensions} \\
\hline
\frac{1}{g^2} & \leftrightarrow & \frac{\ell}{g_5} \\
v & \leftrightarrow & \frac{1}{\sqrt{\ell g_5}} \\
q & \leftrightarrow & e^{-k\ell} \\
\end{array}
\]

Table 3.1. Dictionary between a quiver theory and a gauge theory with 5 dimensional discretized with a curve extra dimension.

with \( v \lesssim M_P = 10^{19} \text{ GeV} \) and \( v_N \simeq \mathcal{O}(1) \text{ TeV} \),

\[
e^{-kN\ell} = \frac{v_N}{v} \simeq 10^{-16}, \tag{3.79}
\]

and then

\[
q \simeq 10^{-16/N}. \tag{3.80}
\]

In the continuum limit we have that (3.79) corresponds to the expression in AdS\(_5\) theories with metric given by (3.73). So we see that the deconstruction of AdS\(_5\) can be seen as a way to obtain four-dimensional theories that solve the hierarchy problem. This will be the case as long as (3.80) is satisfied. However, for large values of \( N \) the four-dimensional theory is very similar to AdS\(_5\). In order to obtain a very different theory from deconstruction, \( N \) must be small.

From (3.80) we can infer the following relation

\[
k\ell \sim \frac{37}{N}, \tag{3.81}
\]

identifying two cases, the first one is if \( N > 37 \), this means that \( k\ell < 1 \) or \( k < \Lambda_{UV} \), we still have an AdS\(_5\) theory. But if \( N < 37 \), then \( k\ell > 1 \) or \( k > \Lambda_{UV} \), then \( N < 37 \), we will have a pure four-dimensional theory different from AdS\(_5\), since no continuum limit possible since curvature is larger than \( M_{Planck} \).
3.1.2 Higgs in Quiver Theories

In the SM, the Higgs boson is required in order to trigger EWSB. However we do not know how the Higgs sector was obtained in low energies. One possibility to consider is the Higgs as a pNGB as shown in Refs. [23, 33, 34, 35]. The discovery of the Higgs boson of the SM [1, 2], suggests that we need to focus not only on gauge bosons and fermions, as we will see in the next subsection, but on the Higgs sector of quiver theories as recently considered in Refs. [8, 9, 10, 12, 36]. In this section we include the Higgs as a pNGB. This is achieved by switching on the gauge fields associated to $G_j$, with $j = 1, ..., N - 1$, and reducing the gauge groups $G_0$ to $H_0$ and $G_N$ to $H_N$ so that some of the NGBs are not eaten by gauge bosons. Here $H_0$ and $H_N$ are subgroups of $G_0$ and $G_N$ respectively. Consequently, to consider the Higgs as a pNGB, the gauge structure given in Figure (3.4) needs to be modified.

![Quiver diagram associated with a quiver theory considering the Higgs as a pNGB](image)

Figure 3.7: Quiver diagram associated with a quiver theory considering the Higgs as a pNGB, where $G_j = SU(3)$, $0 < j < N$ and $H_0 = H_N = SU(2) \times U(1)$ will be gauged.

Here, we would have four degrees of freedom that will be identified with the degrees of freedom of the Higgs doublet, after the breaking of the quiver symmetry. In particular, we will switch on the gauge fields associated to $SU(3)_j$ for $1 < j < N - 1$ and $H_0 = H_N = SU(2) \times U(1)$, the gauge structure in this case is given by the quiver diagram in Figure (3.7). In this way, in the 0 and $N$ sites, the symmetry $SU(2) \times U(1)$ not include the generators associated to $SU(3)/SU(2) \times U(1)$, where the matrices in the fundamental representation of $SU(3)$ are given by the eight Gell-Mann matrices

$$T^a = \frac{\lambda^a}{2}.$$

These matrices are given by
\[
\begin{align*}
\lambda^1 &= \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, & \lambda^2 &= \begin{pmatrix} 0 & -i & 0 \\ i & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, & \lambda^3 &= \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \\
\lambda^4 &= \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}, & \lambda^5 &= \begin{pmatrix} 0 & 0 & -i \\ 0 & 0 & 0 \\ i & 0 & 0 \end{pmatrix}, & \lambda^6 &= \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}, \\
\lambda^7 &= \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -i \\ 0 & i & 0 \end{pmatrix}, & \lambda^8 &= \frac{1}{\sqrt{3}} \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -2 \end{pmatrix}.
\end{align*}
\] (3.83)

We define the matrices
\[
Y^a \equiv \{T^1, T^2, T^3, T^8\} \quad (3.84)
\]
and
\[
X^\alpha \equiv \{T^4, T^5, T^6, T^7\}, \quad (3.85)
\]
are the generators associated to \(SU(2) \times U(1)\) and \(SU(3)/SU(2) \times U(1)\) respectively. We use the convention that Latin and Greek indices take values of 1, 2, 3, 8 and 4, 5, 6, 7, respectively. Notice that the generators \(X^\alpha\) will be associated with the degrees of freedom of the Higgs doublet. Now, we will expand the kinetic term of the \(\Phi_j\)'s, such that we will consider only quadratic terms in the NGBs and gauge fields associated to the generators \(X^\alpha\)

\[
\begin{align*}
\frac{1}{2} [\partial_\mu \pi^\alpha_1 - v_1 g A^\alpha_\mu] &+ \sum_{j=2}^{N-1} \frac{1}{2} [\partial_\mu \pi^\alpha_j - v_j g (A^\alpha_{\mu j} - A^\alpha_{\mu,j-1})]^2 \\
&+ \frac{1}{2} [\partial_\mu \pi^\alpha_N + v_N g A^\alpha_{\mu N}]^2.
\end{align*}
\] (3.86)

The cross terms mixing the NGB's with the gauge bosons associated to \(X^\alpha\) can be canceled by introducing the gauge-fixing term

\[
L_G = -\sum_{j=1}^{N-1} \frac{1}{2\xi} [\partial_\mu A^{\mu\alpha}_j - \xi g (v_j \pi^\alpha_j - v_j v_{j+1} \pi^\alpha_{j+1})]^2.
\] (3.87)
After adding this gauge-fixing term to expansion in (3.86), we obtain
\[
\frac{1}{2} \sum_{j=1}^{N} (\partial_\mu \pi_j^a)^2 - \sum_{j=1}^{N-1} \frac{1}{2\xi} (\partial_\mu A^\mu_\alpha_j)^2 - \frac{1}{2} \sum_{j=1}^{N-1} \xi [g(v_j^{\pi_j^a} - v_{j+1}^{\pi_{j+1}^a})]^2 + \frac{1}{2} \sum_{j=2}^{N-1} v_j^2 g^2 (A^\mu_\alpha_j - A^\mu_\alpha_{j-1})^2 - \frac{1}{2} g^2 v_1^2 (A^\mu_\alpha_1)^2 - \frac{1}{2} g^2 v_N^2 (A^\mu_\alpha_{N-1})^2. \tag{3.88}
\]

Here, we identify the mass matrix \(M^2_{A^\alpha}\) for the gauge bosons associated to \(X^\alpha\), this is given by
\[
M^2_{A^\alpha} = g^2 v^2 \begin{pmatrix}
q^2 + q^4 & -q^4 & 0 & 0 & \cdots & 0 & 0 \\
-q^4 & q^4 + q^6 & -q^6 & 0 & \cdots & 0 & 0 \\
0 & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
0 & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
0 & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
0 & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & 0 & 0 & \cdots & -q^{2N} & q^2(N-1) + q^{2N}
\end{pmatrix}, \tag{3.89}
\]
where we used the parametrization (3.36). We also identify the mass matrix \(M^2_{\pi^\alpha}\) for the NGBs associated to \(X^\alpha\) as follow
\[
M^2_{\pi^\alpha} = g^2 v^2 \xi \begin{pmatrix}
q^2 & -q^3 & 0 & 0 & \cdots & 0 & 0 \\
-q^3 & 2q^4 & -q^5 & 0 & \cdots & 0 & 0 \\
0 & -q^5 & 2q^6 & -q^7 & \cdots & 0 & 0 \\
\vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
0 & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
0 & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & 0 & 0 & \cdots & 2q^{2(N-1)} & -q^{2N-1} \\
0 & 0 & 0 & 0 & \cdots & -q^{2N-1} & q^{2N}
\end{pmatrix}. \tag{3.90}
\]
But now, unlike in the case of (3.45), the determinant vanishes:
\[
\text{Det}[M^2_{\pi^\alpha}] = 0. \tag{3.91}
\]
This indicates that the NGBs associated to \(X^\alpha\) have a zero mode in their mass eigenstate basis. This mode is a physical state due the fact that, in the unitary gauge, that is, \(\xi \to \infty\), this state will not disappear from the theory.

Now, we will define the orthonormal rotation that diagonalizes \(M^2_{\pi^\alpha}\)
\[
\pi_j^\alpha = \sum_{n=1}^{N} b^{j,n} \pi^{\alpha \alpha (n)}, \tag{3.92}
\]
where the index \(n\) indicates the eigenmode. Since we are interested in the zero mode, we focus on \(b^{j,0}\), henceforth we will denote it as \(b^j\). It is possible to show
(using the eigenvalue equation associated to $M_{2\alpha}^2$ for the zero eigenvalue) that,

$$b^j = \frac{q^{N-j}}{\sqrt{\sum_{j=1}^{N} q^{2(j-1)}}}, \quad (3.93)$$

where we used the normalization condition

$$\sum_{j=1}^{N} |b^j|^2 = 1. \quad (3.94)$$

Then, by using (3.92) and (3.93), we obtain

$$\pi^\alpha (0) = \sum_{j=1}^{N} \frac{q^{N-j}}{\sqrt{\sum_{j=1}^{N} q^{2(j-1)}}} \pi_j^\alpha. \quad (3.95)$$

The expression (3.93) indicates that the Higgs is always localized close the N-th site. This fact will be used in Subsection 3.1.5.

Also, we notice that the combination $\pi_j^\alpha X^\alpha$ gives

$$\pi_j^\alpha X^\alpha = \frac{1}{2} \begin{pmatrix} 0 & 0 & \pi_j^4 - i\pi_j^5 \\ 0 & 0 & \pi_j^5 - i\pi_j^4 \\ \pi_j^4 + i\pi_j^5 & \pi_j^5 + i\pi_j^7 & 0 \end{pmatrix}, \quad (3.96)$$

where the Higgs doublet $H$, as shown in Ref. [10], is identified as $(h_1 \ h_2)^T$, where $h_1$ and $h_2$ are given by $\frac{1}{\sqrt{2}}(\pi_j^4 - i\pi_j^5)$ and $\frac{1}{\sqrt{2}}(\pi_j^6 - i\pi_j^7)$ respectively.

In this way, we have obtained a Higgs out of the breaking of the (partially gauged) global symmetry $H_0 \times G_1 \times \ldots \times G_{N-1} \times H_N$. Is this global symmetry that protects the Higgs mass.

### 3.1.3 Fermions in Quiver Theories

We will study the spectrum of Vector-like quarks in quiver theories and their couplings to gauge bosons and the Higgs as can be found in Ref. [10]. Then the phenomenology will be done in the following chapter.
The fermions are included in the quiver theories by the following action:

\[
S_\psi = \int d^4x \left\{ \sum_{j=0}^{N} \left[ \bar{\psi}_{L,j} i D_j \psi_{L,j} + \bar{\psi}_{R,j} i D_j \psi_{R,j} - (\mu_j \bar{\psi}_{L,j} \psi_{R,j} + \text{h.c.}) \right] - \sum_{j=1}^{N} \lambda (\bar{\psi}_{R,j-1} \Phi_j \psi_{L,j} + \text{h.c.}) \right\},
\]

(3.97)

where the fermions \(\psi_j\) are vector-like, transform in the fundamental representation of \(SU(n)_j\), \(\lambda\) are Yukawa couplings, and \(\mu_j\) is the mass term in the interaction eigenstates.

Using the link fields in terms of their VEVs (3.36), as shown in Refs. [7, 8, 10, 12]. In addition, we need to consider the next relations that were shown in Ref. [7]

\[
\mu_j = -g v q^{c+j+1/2}, \quad \lambda = g,
\]

(3.98)

where \(c\) is the localization parameter for fermions associated to AdS\(_5\) theories for fermions in the Bulk. Now, we can identify the mass term for the fermions in the Lagrangian associated with the action (3.97) as

\[
\mathcal{L}_M = - \sum_{j=0}^{N} (\mu_j \bar{\psi}_{L,j} \psi_{R,j} + \text{h.c.}) - \sum_{j=1}^{N} \lambda v_j (\bar{\psi}_{R,j-1} \psi_{L,j} + \text{h.c.}) \equiv - \Psi_L M_\psi^T \Psi_R + \text{h.c.},
\]

(3.99)
where $\Psi_{L/R}^T$ was written in the basis $\Psi_{L/R}^T = (\psi_{L/R,0}; \psi_{L/R,1}, \ldots, \psi_{L/R,N})$, we can change from this basis to the mass eigenstate basis as follow

$$\psi_{L/R,j} = \sum_{n=0}^{N} h_{L/R}^{j,n} \chi_{L/R}^{(n)},$$

(3.100)

where $\chi_{L/R}^{(n)}$ are the mass eigenstate. Thus, to find $\psi_{L,j}$ as a linear combination of $\chi_{L}^{(n)}$, we can obtain it by diagonalizing the matrix

$$M_\psi^T M_\psi = \begin{pmatrix}
\mu_0^2 & \lambda \mu_0 v_1 & 0 & \cdots & 0 & 0 \\
\lambda \mu_0 v_1 & \lambda^2 v_1^2 + \mu_1^2 & \lambda \mu_1 v_2 & \cdots & 0 & 0 \\
0 & \lambda \mu_1 v_2 & \lambda^2 v_2^2 + \mu_2^2 & \cdots & 0 & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & 0 & \cdots & \lambda^2 v_{N-1}^2 + \mu_{N-1}^2 & \lambda \mu_{N-1} v_N \\
0 & 0 & 0 & \cdots & \lambda \mu_{N-1} v_N & \lambda^2 v_N^2 + \mu_N^2
\end{pmatrix}.$$  

Analogously we diagonalize the matrix $M_\psi M_\psi^T$ to obtain $\psi_{R,j}$ as a linear combination of $\chi_{R}^{(n)}$. Now, we need to indicate if the action (3.97) belongs to a fermion with left- or right- handed zero mode. Thus, the case where we will have a fermion with left-handed zero mode is achieved by taking $\mu_N = 0$, it corresponds to the
quiver diagram of Figure (3.8), in this case the linear combination

\[ \psi_{L,j} = \sum_{n=0}^{N} h_{L}^{i_{n}}(c_{L})\chi_{L}^{(n)} \] (3.101)

is found by diagonalizing the matrix

\[ M_{\psi}^{T}M_{\psi} = g^{2}v^{2} \begin{pmatrix} q^{c_{L}+\frac{1}{2}} & -q^{c_{L}+\frac{3}{2}} & \ldots & 0 & 0 \\ -q^{c_{L}+\frac{5}{2}} & q^{2c_{L}+3} + q^{2} & \ldots & 0 & 0 \\ 0 & -q^{c_{L}+\frac{7}{2}} & \ldots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \ldots & q^{2c_{L}+2N-1} + q^{2(N-1)} & -q^{c_{L}+\frac{1}{2}(4N-1)} \\ 0 & 0 & \ldots & -q^{c_{L}+\frac{1}{2}(4N-1)} & q^{2N} \end{pmatrix} \].

(3.102)

To write this matrix explicitly, the parametrizations (3.36) and (3.98) were used.

On the other hand, if we take \( \mu_{0} = 0 \), we will have a fermion with right-handed zero mode, for this case the quiver diagram corresponds to Figure (3.9), such that the linear combination

\[ \psi_{R,j} = \sum_{n=0}^{N} h_{R}^{i_{n}}(c_{R})\chi_{R}^{(n)} \] (3.103)

can be found by diagonalizing the matrix

\[ M_{\psi}M_{\psi}^{T} = g^{2}v^{2} \begin{pmatrix} q^{2} & -q^{c_{R}+\frac{5}{2}} & \ldots & 0 & 0 \\ -q^{c_{R}+\frac{5}{2}} & q^{4} + q^{2c_{R}+3} & \ldots & 0 & 0 \\ 0 & -q^{c_{R}+\frac{7}{2}} & \ldots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \ldots & q^{2c_{R}+2N-5} + q^{2(N-2)} & -q^{c_{R}+\frac{1}{2}(4N-7)} \\ 0 & 0 & \ldots & -q^{c_{R}+\frac{1}{2}(4N-7)} & q^{2c_{R}+2N-3} \end{pmatrix} \],

(3.104)

where we used the parametrizations (3.36) and (3.98). Notice that the values of \( c_{L,R} \) for fermions zero mode of the SM were found in Ref. [8].
3.1 Quiver Theories

3.1.3.1 Equation of Motion for $\psi_L^{(n)}$ and $\psi_R^{(n)}$

We saw that $\chi_L^{(n)}$ and $\chi_R^{(n)}$ are the mass eigenstates. We will impose that they satisfy the Dirac equation

\[
i\slashed{\partial} \chi_L^{(n)} - m_n \chi_R^{(n)} = 0, \tag{3.105}\]
\[
i\slashed{\partial} \chi_R^{(n)} - m_n \chi_L^{(n)} = 0. \tag{3.106}\]

On the other hand the equations of motion can be obtained from (3.97). Expressing the link fields in terms of their VEVs, we obtain

for $\bar{\psi}_{R,j}$:
\[
i \slashed{\partial}\bar{\psi}_{R,j} + \lambda v_j \psi_{L,j} + \mu_j \psi_{L,j+1} + \psi_{L,j} = 0, \tag{3.107}\]

for $\bar{\psi}_{L,j}$:
\[
i \slashed{\partial}\bar{\psi}_{L,j} + \lambda v_j \psi_{R,j} - \mu_j \psi_{R,j-1} + \psi_{R,j} = 0. \tag{3.108}\]

Using (3.109), (3.107) and (3.108) we obtain

\[
m_n h_R^{j,n} + \mu_j h_L^{j,n} + \lambda v_j h^{j+1,n}_R = 0, \tag{3.109}\]
\[
m_n h_L^{j,n} + \mu_j h_R^{j,n} + \lambda v_j h^{j-1,n}_R = 0, \tag{3.110}\]

where the equations (3.109) and (3.110) are coupled. After decoupling these we obtain

\[
(\mu_j^2 + \lambda^2 v_j^2 - m_n^2) h_L^{j,n} + \lambda \mu_j v_{j+1} h^{j+1,n}_L + \lambda \mu_{j-1} v_j h^{j-1,n}_L = 0, \tag{3.111}\]
\[
(\mu_j^2 + \lambda^2 v_{j+1}^2 - m_n^2) h_R^{j,n} + \lambda \mu_{j+1} v_{j+1} h^{j+1,n}_R + \lambda \mu_j v_j h^{j-1,n}_R = 0. \tag{3.112}\]

In the next subsection we will obtain the analytical zero mode wave functions by imposing conditions to have a left-handed zero mode or a right-handed zero mode.

Zero Mode Wave-Function

To obtain the SM fermion spectrum as the zero modes, we can impose as boundary condition $h_R^{N,n} = 0$, that is $\psi_{R,N} = 0$ to obtain a left-handed zero mode, or we can impose $h_L^{0,n} = 0$, that corresponds to $\psi_{L,0} = 0$ to obtain a right-handed zero mode.

In the case of a left-handed zero mode, we use (3.109) to obtain

\[
\mu_j h_L^{j,0} + \lambda v_{j+1} h_L^{j+1,0} = 0,
\]
which is equivalent to
\[ \frac{h_{L}^{j+1,0}}{h_{L}^{j,0}} = q^{c_{L}^{-1/2}}. \] (3.113)

Since \( 0 < q < 1 \), for \( c_{L} > 1/2 \) the left-handed zero mode wave function will be “localized” close to the zero site corresponding to the left side of quiver diagram in Figure (3.8), and for \( c_{L} < 1/2 \) it will be localized close to the N site, that corresponds to the right side of the quiver diagram in Figure (3.9). The 0 site corresponds to the UV scale because \( v_{1} \) is largest and the N site corresponds to the IR scale because \( v_{N} \) is the smallest VEV. Nothing to do with fermion localization.

Alternatively, if we consider a right-handed zero mode, we use (3.110) to obtain
\[ \mu_{j} h_{R}^{j,0} + \lambda v_{j} h_{R}^{-1,0} = 0, \]
and then
\[ \frac{h_{R}^{j,0}}{h_{R}^{-1,0}} = q^{-(c_{R}+1/2)}. \] (3.114)
So for \( c_{R} > -1/2 \) the right-handed zero mode wave function is localized in the N site (IR), on the other hand for \( c_{R} < -1/2 \) it will be localized closer to the zero site (UV).

To obtain an analytical expression for the zero mode wave functions for the fermions, we write
\[ h_{L,R}^{j,0} = z_{L,R}^{j} h_{L,R}^{0,0}, \] (3.115)
where we have considered the definitions \( z_{L} \equiv q^{c_{L}^{-1/2}} \) and \( z_{R} \equiv q^{-(c_{R}+1/2)} \), such that the normalization conditions for the zero mode wave functions can be written as follows
\[ \sum_{j=0}^{N} |h_{L,R}^{j,0}|^2 = |h_{L,R}^{0,0}|^2 \sum_{j=0}^{N} z_{L,R}^{2j} = 1, \] (3.116)
and then we obtain
\[ h_{L,R}^{0,0} = \sqrt{\frac{1 - z_{L,R}^2}{1 - z_{L,R}^{2(N+1)}}}. \] (3.117)

So if the zero mode wave function of a fermion is closer to the N site associated to the scale (IR), this has more coupling with the Higgs. In analogous way, if the zero mode wave function of a fermion is localized closer to the zero site, such that it is associated to the scale UV, it has less coupling with the Higgs, given that the Higgs is localized close to the N-th site.
The quiver theories will have characteristics similar to AdS$_5$ theories, but from this point of view we can say that they have different phenomenology, in important aspects of the theory. We mention that the AdS$_5$ theories are a particular case of quiver theories in the continuum limit.

**Spectrum of Excited States**

To understand the phenomenology, such as the production or decay of the excited fermions in quiver theories, we need to compute the spectrum of these excited states. Based on Subsection 3.1.3 we computed the masses of the excited fermions ($n > 0$) by diagonalizing the fermion mass matrices (3.102) or (3.104) to have left- and right-handed zero modes, respectively. Once we have fixed $N$ jointly with $v = M_P = 10^{19}$ GeV and $v_N = 1$ TeV, then these matrices will depend on the localization parameters.

Thus the masses for the first excited states of fermions with left-handed zero modes are shown in Figure (3.10), for $c_L > 0.5$, i.e., in which their left-handed zero modes wave functions are localized in the UV sites; the masses will be of order $v_N$, differently, for $c_L < 0.5$, the masses will be exponentially heavier.

The case when there are right-handed zero modes, the masses for the first excited states of fermions are shown in Figure (3.11). We see that for $c_R > -0.5$, i.e., the case in which their right-handed zero modes wave functions are localized in the IR sites; similarly to the previous case, the masses will be of order $v_N$ and be exponentially heavier for $c_R < -0.5$.

**Figure 3.10.** Masses of the first excited states of the fermions that belong to their tower with left-handed zero mode, the solid and dashed lines correspond to $N=4$, 15, respectively.
Having computed the wave functions and mass spectrum for the fermion excitations, their couplings will be computed below.

3.1.4 Couplings of Fermionic Excited States

Based in the approach of $[10, 11, 12]$ we can now compute the couplings of the excited fermions to the gauge bosons and the Higgs sector in the frame of quiver theories. The rest of this subsection is organized as follows: First, we show how to compute the couplings of the excited fermions to gauge boson excitations, for both cases left- and right-handed fermion zero modes. We will concentrate in computing the couplings of the zero-mode fermions, for the cases of the first and third generations of quarks, to the first excited state of a gluon. In addition, the couplings of the excited fermions to their zero mode and the first excited gauge bosons. Afterwards we shall focus on obtaining the couplings of the fermions considered in the previous subsection to the Higgs sector. The relevant wave functions showing in Appendix $A$ will be used below.

3.1.4.1 Couplings to Gauge Bosons

We will obtain the coupling of the excited fermions to gauge boson excitations in the quiver theories. These couplings are included in the kinetic terms in (3.97). We first consider the case where the spectrum includes a fermion with a left-
handed zero mode, as follows

\[ \mathcal{L}_{\psi_L A} = \sum_{j=0}^{N} \tilde{g}_j \bar{\psi}_{L,j} \gamma^\mu A_{\mu,j} \psi_{L,j}, \quad (3.118) \]

where \( \tilde{g}_j \) is the gauge coupling associated with the \( SU(n)_j \) gauge group, \( \psi_{L,j} \) and \( A_{\mu,j} \) are interaction eigenstates associated to the site \( j \), such that \( j = 0, 1, \ldots, N \).

Now, we can write the fields included in (3.118) by using their mass eigenstates basis (3.49) and (3.101). Note also in this case that \( h_{L}^{j,n} \) is given in (3.100) and obtained by diagonalizing the matrix \( M_{\psi}^T M_{\psi} \) (3.102) by taking \( \mu_N = 0 \), such that (3.118) can be written as

\[ \mathcal{L}_{\psi_L A} = \sum_{j,n,m,p=0}^{N} \left[ \tilde{g} (h_{L}^{j,n})^* f^{j,m} h_{L}^{j,p} \right] \bar{\chi}_{L}^{(n)} \gamma^\mu A_{\mu}^{(m)} \chi_{L}^{(p)}, \quad (3.119) \]

where we have used the expansion given in (3.49), \( A_{\mu}^{(m)} = A_{\mu}^{a(m)} T^a \) and \( \tilde{g}_j \) was assumed to be equal to \( \tilde{g} \). We also define the effective coupling of the \( n \) and \( p \) fermion excitations to the \( m \) gauge boson excitation as

\[ g_{L}^{n,m,p} \equiv \tilde{g} \sum_{j=0}^{N} \left[ (h_{L}^{j,n})^* f^{j,m} h_{L}^{j,p} \right]. \quad (3.120) \]

Notice that in (3.120), for a given number of sites in this model, this \( g_{L}^{n,m,p} \) depends on the value of \( c_L \) according to (3.101). In addition, it allows the mixing between different modes of a left-handed fermion to a gauge boson excitation.

Now, to establish the relation between \( \tilde{g} \) and the SM couplings, \( g_{L}^{n,m,p} \) in (3.120), we impose that for \( n = m = p = 0 \)

\[ g_{L}^{0,0,0} = \tilde{g} \sum_{j=0}^{N} \left[ (h_{L}^{j,0})^* f^{j,0} h_{L}^{j,0} \right], \quad (3.121) \]

we obtain the corresponding SM gauge coupling of the zero modes. We can use (3.62) and the fact the \( h_{L}^{j,0} \) satisfies the normalization condition for a given value of \( c_L \). The coupling \( g_{L}^{0,0,0} \) in (3.121) may be written in the form

\[ g_{L}^{0,0,0} = \frac{\tilde{g}}{\sqrt{N+1}} \sum_{j=0}^{N} \left[ (h_{L}^{j,0})^* h_{L}^{j,0} \right]; \quad (3.122) \]

from which we obtain

\[ g_{L}^{0,0,0} = g = \frac{\tilde{g}}{\sqrt{N+1}}, \quad (3.123) \]
where $g$ is the gauge coupling of the SM, so (3.124) yields
\[
\tilde{g} = g\sqrt{N + 1},
\] (3.124)
and then substituting (3.124) into (3.120). We find then that
\[
g_{L}^{n,m,p} = g\sqrt{N + 1} \sum_{j=0}^{N} [(h_{L}^{j,n})^* f^{j,m} h_{L}^{j,p}].
\] (3.125)

On the other hand, in the case of a fermion with right-handed zero mode, we proceed in a similar way, analogously to the previous case. We have
\[
\mathcal{L}_{\psi_{L,A}} = \sum_{j=0}^{N} \tilde{g}_{j} \bar{\psi}_{R,j} \gamma^{\mu} A_{\mu,j} \psi_{R,j}.
\] (3.126)

Thus, considering this type of spectrum we can write
\[
g_{R}^{n,m,p} = g\sqrt{N + 1} \sum_{j=0}^{N} [(h_{R}^{j,n})^* f^{j,m} h_{R}^{j,p}].
\] (3.127)

where for a fixed number of sites, $g_{R}^{n,m,p}$ will depend on the value of $c_{R}$, since in this case $h_{R}^{j,n}$ is obtained diagonalizing the matrix $M_{\psi}M_{\psi}^{T}$ (3.104) by taking $\mu_{0} = 0$. In subsections (3.1.4.1) and (3.1.4.1) we will show some results, for couplings that involve a first excited state of a gauge boson to excited fermions.

**Zero Mode**

Here we perform a numerical calculation, first to obtain the couplings of the left-handed zero mode to a first excited state of a gauge boson, i.e. $g_{L}^{0,1,0}(c_{L})$. Using (3.125), we obtain this coupling as a function of the localization parameter $c_{L}$, for specific quiver theories with five and sixteen sites, i.e. $N = 4$ and $N = 15$ respectively. As shown in Figure (3.12), that agrees with the analytical calculation obtained in the previous Refs. [8, 9, 11]. In this plot there are two plateaus: the upper plateau, for $c_{L} < 0.5$ corresponds to left-handed fermions whose zero modes are localized close to the $N$-th site, that is, in the IR region. And the lower plateau, for $c_{L} > 0.5$, where the left-handed fermions have their zero modes localized close to the zeroth site, that is, in the UV region.
Figure 3.12. Couplings of the left-handed zero mode to a first excited state of a gauge boson, in units of the SM gauge boson coupling, as a function of the localization parameter. For $N=4$, $N=15$.

Figure 3.13. Couplings of the fermions with right-handed zero mode to a first excited state of gauge boson, in units of the SM gauge boson coupling, as a function of the localization parameter. For $N=4$, $N=15$.

We also obtain the couplings of the fermions with a right-handed zero-mode
to a first excited state of gauge boson, i.e. \( g_{R}^{0,1,0}(c_{R}) \), as a function of the localization parameter \( c_{R} \), for specific quiver theories with five and sixteen sites, i.e. \( N = 4 \) and \( N = 15 \) respectively, \( (3.125) \) was used.

The Figure \( (3.13) \) shows this calculation, which is in agreement with the analytical calculation obtained in the previous Refs. \[8, 9, 11\]. In this plot there are also two plateaus: the lower plateau, for \( c_{R} < -0.5 \), corresponds to right-handed zero-mode fermions localized close to the zeroth site, that is, in the UV region. And the upper plateau, for \( c_{R} > -0.5 \), corresponds to right-handed zero-modes localized close to the \( N \)-th site, that is, in the IR region.

**Off Diagonal Couplings**

We will compute the off diagonal couplings involving the first excited fermion, a zero-mode fermion and a first excitation of gauge boson. This will be later used to study the phenomenology of the excited fermions. A similar procedure was followed to obtain the values of the couplings of the first excited fermions to their zero mode and the first excited of a gauge boson. We use \( (3.120) \) and \( (3.127) \) with \( n=0 \) and \( m=p=1 \), then we can substitute these values to obtain

\[
g_{L}^{0,1,1} = g\sqrt{N + 1} \sum_{j=0}^{N} [(h_{L}^{j,0})^{*} f_{j}^{1,1} h_{L}^{j,1}] ,
\]

\[
g_{R}^{0,1,1} = g\sqrt{N + 1} \sum_{j=0}^{N} [(h_{R}^{j,0})^{*} f_{j}^{1,1} h_{R}^{j,1}] .
\]

As we have already mentioned, \( g_{L}^{0,1,1} \) and \( g_{R}^{0,1,1} \) depend on the values of \( c_{L} \) and \( c_{R} \). These couplings appear in the effective Lagrangian as

\[
g_{L}^{0,1,1} \bar{\chi}^{(0)}_{L} \gamma^{\mu} A_{\mu}^{(1)} \chi_{L}^{(1)} + \text{h.c.}
\]

and

\[
g_{R}^{0,1,1} \bar{\chi}^{(0)}_{R} \gamma^{\mu} A_{\mu}^{(1)} \chi_{R}^{(1)} + \text{h.c.}
\]

To calculate the couplings in \( (3.128) \) and \( (3.129) \), the localization parameters \( c_{L,R} \) that are found in Refs. \[8, 11\] were used. This choice corresponds to a solution that gives the correct quark masses as well as the correct CKM matrix. In addition, we considered the values of \( c_{L,R} \) for the first and third generation of SM quarks. These localization parameters are \( c_{uR} = -0.73 \), \( c_{uL} = 0.62 \), \( c_{dR} = -0.96 \), and \( c_{dL} = 0.62 \).
and \( c_{tR} = -0.12, c_{tL} = 0.51, c_{bR} = -0.61 \) for the first and third generation respectively.

The results are displayed in Table (3.2), as shown in Ref. [10]. The column labeled \( 'u^{(1)}' \) gives the values of the couplings between the first excited state of the up quark from the first-generation of the SM to their zero mode, i.e., the up quark and the first excited state of a gauge boson \( A^{(1)} \) in units of the zero-mode SM gauge coupling obtained by using the values of localization parameters \( c_{uL} \) and \( c_{uR} \), for left and right handed chiralities, and for quiver theories with \( N = 4 \) or \( N = 15 \).

Analogously, the column labeled \( 'd^{(1)}' \) contains the values of the couplings between the first excited state of the down quark from the first-generation of the SM to their zero mode, i.e., the down quark and the first excited state of a gauge boson \( A^{(1)} \) in units of the zero-mode SM gauge coupling. In this case we used the values of localization parameters \( c_{uL} \) and \( c_{uR} \). On the other hand the columns labeled respectively \( 't^{(1)}' \) and \( 'b^{(1)}' \), were obtained by using the values of the localization parameters \( c_{tR}, c_{tL} \) and \( c_{bR} \), for left and right handed chiralities, and for quiver theories with \( N = 4 \) or \( N = 15 \). As can be seen, just the largest couplings are found in the third generation, particularly the right-handed top sector for a quiver theory with \( N = 15 \). This is in agreement with the overlap of the wave-functions that were shown in Figures (3.5) and (3.6) for the gauge boson and top fermion with right-handed zero mode and localization parameter \( c_{R} \) for a quiver theory with \( N = 15 \).

| N | L  | R  | L  | R  |
|---|----|----|----|----|
| 4 | 0.028 | 5.2 \times 10^{-4} | 0.028 | 1.1 \times 10^{-7} |
|   | 0.85 | 0.075 | 0.85 | 0.04 |
| 15| 0.033 | 7.1 \times 10^{-4} | 0.033 | 1.7 \times 10^{-7} |
|   | 0.83 | 1.49 | 0.83 | 0.046 |

Table 3.2. The couplings of the first excited fermions to their zero mode and the first excited gauge boson, in units of the zero-mode SM gauge coupling, for \( N=4, N=15 \)

### 3.1.5 Couplings to the Higgs Boson

Based on Subsection \( 3.1.3 \), where it was studied how treat the wave-functions associated to fermions in quiver theories, we now consider the couplings of the excited fermions to the Higgs sector. We will follow the approach from Ref. [10]. Then to obtain these couplings, we need to consider the general form of the fermion couplings to the link fields that contain the Higgs doublet. As we have seen in (3.97), it will involve fermions of the same tower \( \psi_{L,j} \) and \( \psi_{R,j} \) with a
common zero mode, that is, after the application of the boundary condition to have left- or right- handed zero mode.

Moreover, we consider another type of Yukawa terms involving fermions of different towers, as follow

$$\bar{\psi}_{R,j}^{-1}\Phi_j \xi_{L,j},$$

(3.132)

where $\xi_{L,j}$ is associated to a tower with a zero mode, and $\psi_{R,j-1}$ is associated to a tower with a zero mode different from $\xi_{L,j}$. Notice that this term is gauge invariant due also to the transformation (3.31), so is allowed by the theory.

Here the term given in (3.132) is related to the quiver diagram of Figure (3.14). In contrast to the Yukawa terms included in (3.97), where these can be obtained from the deconstruction of AdS$_5$ theory with fermions as shown in Ref. [7] and then these have analog in the continuum limit, the term in (3.132) does not have analog in the continuum limit.

**Figure 3.14.** Quiver diagram including the interaction between fermions of different towers associated to (3.132).

The Higgs is a pNGB extracted from the link fields $\Phi_j$ in the manner explained in Subsection 3.1.2.

The coupling in (3.132) can be written as

$$-\sum_{j=1}^{N} y_j \bar{\psi}_{R,j-1} \Phi_j \xi_{L,j} + h.c.,$$

(3.133)
3.1 Quiver Theories

where the Yukawa couplings $y_j$ in (3.133) are assumed to be $O(1)$, and the fermion fields $\xi_{L,j}$ and $\psi_{R,j-1}$ correspond to different zero modes, characterized by the localization parameters $c_L$ or $c_R$, with appropriate quantum numbers. The Higgs doublet is given by

$$H = \frac{1}{\sqrt{2}} \left( \sqrt{2} \varphi^+ v + H^0 + i \varphi_3 \right).$$

(3.134)

Then, to obtain the couplings of the excited fermions to the Higgs sector, the rotations (3.101) and (3.103) were substituted into (3.133), and the Higgs doublet couplings in (3.133) are rewritten as follows

$$- \sum_{j=1}^{N} \sum_{n,m=0}^{N} y_j (h_{R,j}^{-1,n})^* h_{L,j}^{m} b_j^{(n)} Q_L^{(m)} + H.C.,$$

(3.135)

where $b^j$ is given by (3.93).

Notice that after the quiver symmetry breaking, we still have terms in the theory invariant under $SU(2) \times U(1)$, as mentioned above, and then we consider terms that are invariant under $SU(2)$ and have zero net hypercharge $Y$. Thus, considering mixing of the excited states of quarks belonging to the same family, we can write

$$\mathcal{L} \supset - \sum_{n,m=0}^{N} \sum_{j=1}^{N} y_{uj} (h_{R,j}^{-1,n})^* h_{L,j}^{m} (c_{R_u})^* b_j^{(n)} R_u^{(m)} H^1 L_q^{(m)} + H.C.,$$

$$- \sum_{n,m=0}^{N} \sum_{j=1}^{N} y_{dj} (h_{R,j}^{-1,n})^* h_{L,j}^{m} (c_{R_d})^* b_j^{(n)} R_d^{(m)} H^1 L_q^{(m)} + H.C.,$$

(3.136)

where $\tilde{H} = i \sigma_2 H^*$.

Here $R_u^{(n)}$ and $R_d^{(n)}$ are the excited states of the right-handed up- and right-handed down-type quarks fields, respectively with different right-handed zero modes. Also in (3.136) $L_q^{(m)}$ contains the excited states of the left-handed quarks. After that, we select the coupling between the first excited state of the right-handed up-type quark to the Higgs doublet and the left-handed doublet of SM quarks from the same family as follow

$$- \sum_{j=1}^{N} y_{uj} (h_{R,j}^{-1,1})^* h_{L,j}^{0} (c_{R_u})^* b_j^{(1)} R_u^{(1)} \tilde{H}^1 L_q^{(0)} + H.C.,$$

(3.137)

The results are shown in Table (3.3). For instance, considering the third gener-
ation of SM quarks, i.e., using \((3.137)\), with the localization parameters \(c_{tR}, c_{tL}\) and \((3.93)\), we obtained the couplings displayed in the column labeled \(t_R^{(1)} t_L^{(0)}\), for quiver theories with \(N = 4\) or \(N = 15\). On the other hand the column labeled \(u_R^{(1)} u_L^{(0)}\) were obtained by using the values of the localization parameters \(c_{uR}, c_{uL}\) (corresponding to the first generation of SM quarks).

We also considered the coupling between the right-handed up-type SM quark to the Higgs doublet and the first excited state of the left-handed doublet of quarks associated to the same family as follow

\[
- \sum_{j=1}^{N} y_{uR}(h_{R}^{j-1,0}(c_{R_u}))^* h_{L}^{j,1}(c_{L_q}) b_{R_u} \bar{H}_{L}^{(0)} + \text{h.c.},
\]

The results are also shown in Table \((3.3)\). For instance, considering the third generation of SM quarks, i.e., using \((3.138)\), with the localization parameters \(c_{tR}, c_{tL}\) and \((3.93)\), for the Higgs wave function, we obtained the couplings displayed in the column labeled \(t_L^{(1)} t_R^{(0)}\), for quiver theories with \(N = 4\) or \(N = 5\). Similarly, the values of the couplings in the column labeled \(u_L^{(1)} u_R^{(0)}\) was obtained by using the values of the localization parameters \(c_{uR}, c_{uL}\) (corresponding to the first generation of SM quarks). The next selection of couplings, that we have considered is between the right-handed down-type SM quark to the Higgs doublet and the first excited state of the left-handed doublet of quarks associated to the same family

\[
- \sum_{j=1}^{N} y_{dR}(h_{R}^{j-1,0}(c_{R_d}))^* h_{L}^{j,1}(c_{L_q}) b_{R_d} \bar{H}_{L}^{(0)} + \text{h.c.},
\]

The evaluation for this couplings are also shown in Table \((3.3)\). For instance, considering the third generation of SM quarks, i.e., using \((3.139)\), with the localization parameters \(c_{tR}, c_{tL}\) and \((3.93)\), we obtained the couplings displayed in the column labeled \(t_L^{(1)} t_R^{(0)}\), for quiver theories with \(N = 4\) or \(N = 15\). Similarly, by considering the first generation and showed in the column labeled \(u_L^{(1)} d_R^{(0)}\), where the localization parameters \(c_{dR}, c_{uL}\) were used.

Finally, we also considered the coupling between the first excited state right-handed down-type quark to the Higgs doublet and the left-handed doublet of SM quarks associated to the third generation of SM quarks. This coupling was calculated by using

\[
- \sum_{j=1}^{N} y_{dR}(h_{R}^{j-1,1}(c_{R_d}))^* h_{L}^{j,0}(c_{L_q}) b_{R_d} \bar{H}_{L}^{(0)} + \text{h.c.},
\]
and the results are shown in the column labeled $b_R^{(1)}$, $t_L^{(0)}$, in Table (3.3).

As can be seen in Table (3.3), the larger couplings are found in the third generation. Once again, this agrees with the overlap of the wave-functions associated with the localization parameters ($c_{IL}$, $c_{IR}$ and $c_{bR}$, the wave-functions associated with these localization parameters were obtained in Appendix (A)) and with the (3.93).

Table 3.3. Couplings of fermions from different towers to the Higgs doublet, for allowed modes 0 and 1.

| N  | $t_R^{(1)}$ | $t_L^{(0)}$ | $u_R^{(1)}$ | $u_L^{(0)}$ | $t_L^{(1)}$ | $b_R^{(0)}$ | $u_L^{(1)}$ | $d_R^{(0)}$ | $b_R^{(1)}$ | $t_L^{(0)}$ |
|----|------------|------------|------------|------------|------------|------------|------------|------------|------------|------------|
| 4  | 0.365      | 0.028      | 4.1 $\times$ 10^{-9} | 0.00173    | 0.041      | 3.02 $\times$ 10^{-6} | 0.0143    | 1.28 $\times$ 10^{-7} | 2.64 $\times$ 10^{-4} |
| 15 | 0.179      | 0.352      | 3.4 $\times$ 10^{-5} | 3.02 $\times$ 10^{-4} | 0.0143    | 1.28 $\times$ 10^{-7} | 0.001     |

Now that we have calculated the couplings in this section, we will study in the next chapter the phenomenology of the excited fermions.

3.2 General Effective Theory for New Fermions

Our aim is to provide alternatives to the study of the phenomenology involving new heavy fermions that, besides quiver theories there are also many others Vector-like quarks theories. So it is of interest to study Vector-like quark phenomenology in a general model-independent way. Generically, we can consider vector-like quarks as being multiplets of $SU(2)_L$ as shown in Refs. [37, 38, 39], such that these new fermions will be coupled to SM fermions and gauge bosons through the Yukawa terms and kinetic terms, respectively. Our procedure will be according to Ref. [38], where these new fermions couple to the third generations of SM quarks. In this section, the cases of a singlet vector-like up-type and SM doublet will be studied. For the first case, we will use the bound associated to the $tbW$ coupling [40] and for the second one, the constraint associated to the decay $Z \rightarrow b\bar{b}$ [41] will be used. It is due to after the EWSB the mixing between the vector-like quarks and the third generation of the SM quarks induce deviations on the couplings associated with these measurements. In addition to these cases, for each one the interaction with a heavy gluon will be included.
3.2.1 Vector-like quark SU(2)-singlet up-type, T

Let us consider a vector-like up-type fermion $T'$, a singlet of $SU(2)_L$ with hypercharge equal to $2/3$. It couples to the SM quarks through the Yukawa couplings as follows

$$\mathcal{L}_{Y(VLT)} = -Y^u_{i\beta} q'_L \Phi u'_{R\beta} - Y^d_{ij} q'_L \Phi d'_{Rj} + \text{h.c.},$$

where $i, j = 1, 2, 3$ correspond to indexes of generations in the SM ($q'_L$, $u'_R$ are $SU(2)_L$-doublet and -singlet, respectively) and the index $\beta = 1, 2, 3, 4$, such that $u'_4 = T'$. To indicate that the fermions are not in their mass eigenstate primes are used. In addition, there is a vector-like term of the form

$$\mathcal{L}_{M(VLT)} = -M T'_L T'_R + \text{h.c.},$$

The Higgs doublet is given by

$$\Phi = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ v + H \end{pmatrix}.$$ (3.143)

We substitute (3.143) in (3.141) and considering the mixing between $T'$ and the third generation, we can identify the mass term that is written as follows

$$\mathcal{L}_{\text{Mass}} = - \left( t'_L \quad T'_L \right) M_{t'T'} \left( \begin{array}{c} t'_R \\ T'_R \end{array} \right) + \text{h.c.},$$

where

$$M_{t'T'} = \begin{pmatrix} \frac{v}{\sqrt{2}} Y^u_{33} & \frac{v}{\sqrt{2}} Y^u_{34} \\ 0 & M \end{pmatrix}.$$ (3.145)

We have that the masses in the mass eigenstate are given by

$$m^2_{t_i} = \frac{M^2 + \frac{v^2}{2} (|Y^u_{33}|^2 + |Y^u_{34}|^2) - \sqrt{\left( M^2 + \frac{v^2}{2} (|Y^u_{33}|^2 + |Y^u_{34}|^2) \right)^2 - 2v^2M^2|Y^u_{33}|^2}}{2},$$

$$m^2_{T'} = \frac{M^2 + \frac{v^2}{2} (|Y^u_{33}|^2 + |Y^u_{34}|^2) + \sqrt{\left( M^2 + \frac{v^2}{2} (|Y^u_{33}|^2 + |Y^u_{34}|^2) \right)^2 - 2v^2M^2|Y^u_{33}|^2}}{2},$$

(3.146) (3.147)
by using (3.146), (3.147), jointly with $v^2 \ll M^2$, we can expand the square roots in powers of $\left(\frac{v}{M}\right)^2$ as follow

$$m_t^2 = \frac{M^2 + \frac{v^2}{2} (|Y^u_{33}|^2 + |Y^u_{34}|^2) - M^2 \left[ 1 + \frac{1}{2} \left(\frac{v}{M}\right)^2 (|Y^u_{34}|^2 - |Y^u_{33}|^2) + O\left(\frac{v}{M}\right)^4 \right]}{2},$$

(3.148)

$$m_T^2 = \frac{M^2 + \frac{v^2}{2} (|Y^u_{33}|^2 + |Y^u_{34}|^2) + M^2 \left[ 1 + \frac{1}{2} \left(\frac{v}{M}\right)^2 (|Y^u_{34}|^2 - |Y^u_{33}|^2) + O\left(\frac{v}{M}\right)^4 \right]}{2}.$$

(3.149)

and then $m_t^2$ and $m_T^2$ go as $\left(\frac{v}{\sqrt{2}} Y^u_{33}\right)^2$ and $M^2 + \left(\frac{v}{\sqrt{2}} Y^u_{34}\right)^2$, respectively. Therefore, this means that $m_T$ is greater than the unphysical vector-like mass. Also, using (3.146) and (3.147), we can deduce the relation

$$m_T^2 = M^2 \left( 1 + \frac{\frac{v^2}{2} |Y^u_{34}|^2}{M^2 - m_t^2} \right).$$

(3.150)

This relation is shown in Figure (3.15). We see that the differences between $m_T$ and $M$ decrease for large $M$, whereas for small $M$, these differences increase.

![Figure 3.15](image)

**Figure 3.15.** Correlation between the mass vector-like and $m_T$, for $\frac{v}{\sqrt{2}} |Y^u_{34}| = 100$, 200 and 500 from left to right.
Now, we write $M_{t'T'}$ as factorized as follows

$$M_{t'T'} = V_L^\dagger \begin{pmatrix} m_t & 0 \\ 0 & m_T \end{pmatrix} V_R,$$

(3.151)

where $V_{L,R}$ are given by

$$V_{L,R} = \begin{pmatrix} \cos \theta_{u,u}^L & \sin \theta_{u,u}^L \\ -\sin \theta_{u,u}^L & \cos \theta_{u,u}^L \end{pmatrix},$$

(3.152)

in such a way that the next relations are obtained by using (3.152), (3.151) and (3.145)

$$\begin{align*}
\frac{v}{\sqrt{2}} Y_{33} u \cos \theta_{u}^L \cos \theta_{u}^R - \frac{v}{\sqrt{2}} Y_{34} u \cos \theta_{u}^L \sin \theta_{u}^R + M \sin \theta_{u}^L \sin \theta_{u}^R &= m_t, \\
\frac{v}{\sqrt{2}} Y_{33} u \sin \theta_{u}^L \cos \theta_{u}^R - \frac{v}{\sqrt{2}} Y_{34} u \sin \theta_{u}^L \sin \theta_{u}^R - M \cos \theta_{u}^L \sin \theta_{u}^R &= 0, \\
\frac{v}{\sqrt{2}} Y_{33} u \sin \theta_{u}^L \sin \theta_{u}^R - \frac{v}{\sqrt{2}} Y_{34} u \sin \theta_{u}^L \cos \theta_{u}^R - M \cos \theta_{u}^L \cos \theta_{u}^R &= 0, \\
\frac{v}{\sqrt{2}} Y_{33} u \sin \theta_{u}^L \sin \theta_{u}^R - \frac{v}{\sqrt{2}} Y_{34} u \sin \theta_{u}^L \cos \theta_{u}^R + M \cos \theta_{u}^L \cos \theta_{u}^R &= m_T,
\end{align*}$$

(3.153)

where, assuming real Yukawa couplings, we have

$$\sin \theta_u^L = \frac{v M}{\sqrt{2}} \frac{Y_{34} u}{\sqrt{(M^2 - m_t^2)^2 + v^2 M^2 |Y_{34} u|^2 / 2}},$$

(3.154)

and

$$\sin \theta_u^R = \frac{m_t}{M} \sin \theta_u^L.$$  

(3.155)

To obtain the couplings between $T$ to the SM third generations and the EW gauge bosons we first write the fermion-gauge boson interaction in the EW basis

$$\begin{pmatrix} \bar{T}_L \\ \bar{T}_R \end{pmatrix} i \gamma^\mu \left( -ig A^a_{\mu} \sigma^a - ig' B_{\mu} \right) \begin{pmatrix} t'_L \\ t'_R \end{pmatrix},$$

$$\begin{pmatrix} \bar{T}_L \\ \bar{T}_R \end{pmatrix} i \gamma^\mu \left( -ig B_{\mu} \right) t'_R + \bar{b}'_R i \gamma^\mu \left( -ig' B_{\mu} \right) b'_R,$$

$$\begin{pmatrix} \bar{T}_L \\ \bar{T}_R \end{pmatrix} i \gamma^\mu \left( -ig B_{\mu} \right) T'_L,$$

(3.156)

where $A^a_{\mu}$ and $B_{\mu}$ are the gauge bosons of $SU(2)_L$ and $U(1)_Y$ respectively. In the
following we use the vector mass eigenstates jointly with the rotations defined by (3.152) and, furthermore we will neglect the prime in $b'_L$, because we have considered the mixing between the up sector of the SM third generation and $T'$ according to (3.141) where the down-type quarks are not affected by the mixing. After these substitutions in (3.156), we obtain in the mass eigenstates

$$ \left( \cos \theta^L_u \frac{g}{\sqrt{2}} t_L W^+ b_L + \text{h.c.} \right) $$

$$ + \frac{g}{2c_W} \tilde{b} \tilde{Z} \left( \cos^2 \theta^L_u P_L - \frac{4 s^2_W}{3} \right) b $$

$$ + \frac{g}{2c_W} \tilde{T} \tilde{Z} \left( \sin^2 \theta^L_u P_L - \frac{4 s^2_W}{3} \right) T $$

$$ + \left( \sin \theta^L_u \frac{g}{\sqrt{2}} \tilde{T}_L W^+ b_L + \text{h.c.} \right) $$

$$ + \left( \cos \theta^L_u \sin \theta^L_u \frac{g}{2c_W} \tilde{t} P_L T + \text{h.c.} \right) $$

$$ + \frac{2g_{sw}}{3} \left( \tilde{t} A t + \tilde{T} A T \right) - \frac{g_{sw}}{3} \left( \tilde{b} A b \right), \quad (3.157) $$

while the Higgs interaction involving $T$ and the SM third generation comes from the Yukawa couplings (3.141), by using (3.152), as follows

$$ - \frac{g_{mt}}{2m_W} \sin^2 \theta^L_u \tilde{T} T H $$

$$ - \frac{g_{mt}}{2m_W} \tilde{T} \left( \frac{m_t}{m_T} \cos \theta^L_u \sin \theta^L_u P_R + \cos \theta^L_u \sin \theta^L_u P_L \right) t H + \text{h.c.} $$

$$ - \frac{g_{mt}}{2m_W} \cos^2 \theta^L_u \tilde{t} t H - \frac{g_{mt}}{2m_W} \cos^2 \theta^L_u \tilde{b} b H. \quad (3.158) $$

We can use a CMS measurement of single top cross sections at 7 TeV [40], that is the $V_{tb}$ ($tbW$ coupling), such that $|V_{tb}| > 0.92$, which results in the constraint

$$ |\sin \theta^L_u| < 0.4. \quad (3.159) $$

We point out that $\sin^2 \theta^L_u$ is always further suppressed by $\frac{v}{M}$. The QCD interaction of the Vector-like quark is just as in the SM: $T$, the interaction following is
considered

$$\mathcal{L}_{gTT} = g_s \bar{T} \gamma_\mu T^a g^{\mu,a} T.$$  \hspace{1cm} (3.160)

Finally, we also allow for the interaction of the Vector-like quark with a heavy gluon $G$, given by

$$\mathcal{L}_{GTt} = g_s (f_L \bar{t} L \gamma_\mu T^a G^\mu,a T_L + f_R \bar{t} R \gamma_\mu T^a G^\mu,a T_R + \text{h.c.}), \quad (3.161)$$

where $g_s f_L$ and $g_s f_R$ are left- and right-handed couplings between $t$, $T$ and $G$.

### 3.2.2 Vector-like quark SM SU(2)-doublet

Considering a vector-like SM \( \left( T' \ B' \right)^T \), where it is a doublet of $SU(2)_L$ and has hypercharge 1/6, this couples to the SM quarks in the weak eigenstate through the Yukawa couplings as follow

$$\mathcal{L}_{Y(VLT)} = -Y^u_{ai} \bar{t}^\prime_{La} \Phi u^\prime_{Ri} - Y^d_{aj} \bar{t}^\prime_{La} \Phi d^\prime_{Rj} + \text{h.c.}, \quad (3.162)$$

where $i,j = 1,2,3$ correspond to indexes of generations in the SM ($q_{Li}^\prime$ is a doublet of $SU(2)_L$ and $u_{Ri}^\prime$ is a singlet of $SU(2)_L$) and the index $\alpha = 1,2,3,4$, such that $q_{L,R4}^\prime = \left( T^\prime_{L,R} \ B^\prime_{L,R} \right)^T$, to indicate that the fermions are not in their mass eigenstate primes are used, jointly with the mass vector-like term

$$\mathcal{L}_{M(VLT)} = -M q_{La} q_{R4} + \text{h.c.}. \quad (3.163)$$

Thus we substitute (3.143) in (3.162) and considering the mixing between $T'$, $B'$ and the SM third generation, we can identify the mass term that is written as follows

$$\mathcal{L}_{\text{Mass}} = \left( \bar{T}^\prime_{L} \ T^\prime_{L} \right) \text{M}^u \left( \begin{array}{c} u^\prime_L \\ T^\prime_R \end{array} \right) + \left( \bar{B}^\prime_{L} \ B^\prime_{L} \right) \text{M}^d \left( \begin{array}{c} b^\prime_R \\ B^\prime_R \end{array} \right) + \text{h.c.}, \quad (3.164)$$
Now, we write $M_{u,d}$ as factorized as follows

$$M_{u,d} = V_{L,R}^{u,d} \begin{pmatrix} m_{t,b} & 0 \\ 0 & m_{T,B} \end{pmatrix} V_{R}^{u,d} + h.c., \quad (3.165)$$

where $V_{L,R}^{u,d}$ are given by

$$V_{L,R}^{u,d} = \begin{pmatrix} \cos \theta_{u,d}^{L,R} & \sin \theta_{u,d}^{L,R} \\ -\sin \theta_{u,d}^{L,R} & \cos \theta_{u,d}^{L,R} \end{pmatrix}. \quad (3.166)$$

we also have the relations

$$M_{T,B}^2 = M^2 \left( 1 + \frac{v^2 |Y_{u,d}^{d3}|^2}{2 M^2 - m_{t,b}^2} \right). \quad (3.167)$$

Here the next relations are obtained by using (3.166), (3.165) and (3.164)

$$\frac{v}{\sqrt{2}} Y_{u,d}^{33} \cos \theta_{u,d}^{L} \cos \theta_{u,d}^{R} - \frac{v}{\sqrt{2}} Y_{u,d}^{34} \cos \theta_{u,d}^{L} \sin \theta_{u,d}^{R} + M \sin \theta_{u,d}^{L} \sin \theta_{u,d}^{R} = m_{t,b},$$

$$\frac{v}{\sqrt{2}} Y_{u,d}^{33} \sin \theta_{u,d}^{L} \cos \theta_{u,d}^{R} - \frac{v}{\sqrt{2}} Y_{u,d}^{34} \sin \theta_{u,d}^{L} \sin \theta_{u,d}^{R} - M \cos \theta_{u,d}^{L} \sin \theta_{u,d}^{R} = 0,$$

$$\frac{v}{\sqrt{2}} Y_{u,d}^{33} \sin \theta_{u,d}^{L} \sin \theta_{u,d}^{R} - \frac{v}{\sqrt{2}} Y_{u,d}^{34} \sin \theta_{u,d}^{L} \cos \theta_{u,d}^{R} - M \sin \theta_{u,d}^{L} \cos \theta_{u,d}^{R} = 0,$$

$$\frac{v}{\sqrt{2}} Y_{u,d}^{33} \cos \theta_{u,d}^{L} \sin \theta_{u,d}^{R} - \frac{v}{\sqrt{2}} Y_{u,d}^{34} \cos \theta_{u,d}^{L} \cos \theta_{u,d}^{R} + M \cos \theta_{u,d}^{L} \cos \theta_{u,d}^{R} = m_{T,B}, \quad (3.168)$$

where

$$\sin \theta_{u,d}^{R} = \frac{v M}{\sqrt{2}} \frac{Y_{u,d}^{34}}{\sqrt{(M^2 - m_{t,b}^2)^2 + \frac{v^2 M^2 |Y_{u,d}^{d3}|^2}{2}}} \quad (3.169)$$

and

$$\tan \theta_{u,d}^{L} = \frac{m_{t,b}}{M_{T,B}} \tan \theta_{u,d}^{R}. \quad (3.170)$$

To obtain the couplings between $T, B$ to the SM third generations and the EW
gauge bosons, we first write the fermion-gauge boson interaction in the EW basis

\[
\begin{pmatrix}
    t'_L & b'_L \\
    t'_R & b'_R
\end{pmatrix}
\begin{pmatrix}
    i\gamma^\mu (-igA^a_\mu\tau^a - ig' B_\mu Y)
\end{pmatrix}
\begin{pmatrix}
    t'_L \\
    b'_L
\end{pmatrix}
\]

\[
+ t'_R i\gamma^\mu (-ig' B_\mu Y) t'_L + \bar{b}'_R i\gamma^\mu (-ig' B_\mu Y) b'_R
\]

\[
+ \begin{pmatrix}
    \bar{T}'_L & \bar{B}'_L \\
    \bar{T}'_R & \bar{B}'_R
\end{pmatrix}
\begin{pmatrix}
    i\gamma^\mu (-igA^a_\mu\tau^a - ig' B_\mu Y)
\end{pmatrix}
\begin{pmatrix}
    T'_L \\
    B'_L
\end{pmatrix}
\]

\[
+ \begin{pmatrix}
    \bar{T}'_R & \bar{B}'_R \\
    \bar{T}'_L & \bar{B}'_L
\end{pmatrix}
\begin{pmatrix}
    i\gamma^\mu (-igA^a_\mu\tau^a - ig' B_\mu Y)
\end{pmatrix}
\begin{pmatrix}
    T'_R \\
    B'_R
\end{pmatrix},
\]

in the following we rewrite all interaction terms\(^1\) in the vector mass eigenstates, to do this the following definitions will be considered

\[
e^{u,d}_{L,R} \equiv \cos \theta^{L,R}_{u,d},
\]

\[
s^{u,d}_{u,d} \equiv \sin \theta^{L,R}_{u,d},
\]

Now, we write in the mass eigenstate the Higgs interaction involving \(T, B\) and the SM third generations, which comes from the Yukawa couplings (3.162), by using (3.166), as follows

\[
- \frac{g m_T}{2 m_W} (s^u_R)^2 \bar{T} T H
\]

\[
- \frac{g m_B}{2 m_W} (s^{d}_R)^2 \bar{B} B H
\]

\[
- \frac{g m_T}{2 m_W} \bar{T} \left( \frac{m_t}{m_T} c^u_R s^u_R P_L + s^u_R c^u_R P_R \right) t H + \text{h.c.}
\]

\[
- \frac{g m_B}{2 m_W} \bar{B} \left( \frac{m_b}{m_B} c^d_R s^d_R P_L + s^d_R c^d_R P_R \right) b H + \text{h.c.}
\]

\[
- \frac{g m_t}{2 m_W} (c^u_R)^2 \bar{t} t H - \frac{g m_b}{2 m_W} (c^d_R)^2 \bar{b} b H,
\]

Thus, we can identify from (B.1) the coupling to study the single production of

\(^1\)The passing from the EW to the mass eigenstate can be seen in Appendix (B) by using the definitions given in (3.172) and (3.173).
3.2 General Effective Theory for New Fermions

$T$ via $W$, that is given by

$$\frac{g}{\sqrt{2}} \sin (\theta_L^u - \theta_L^d) T_L W^+ b_L - \frac{g}{\sqrt{2}} \cos \theta_R^u T_R W^+ b_R + \text{h.c.} \quad (3.175)$$

Notice that the angle $\theta_L^d$ is negligible, because is suppressed by the $m_b$ according to (3.170).

In the mass eigenstate basis we have also found terms as

$$-\frac{g}{2c_W} \bar{b}_L Z b_L + \frac{gs_W^2}{3c_W} \bar{b}_L Z b_L - \frac{g}{2c_W} (s_R^d)^2 \bar{b}_R Z b_R, \quad (3.176)$$

and

$$\frac{g}{\sqrt{2}} (c_L^u c_L^d + s_L^u s_L^d) \bar{t}_L W^+ b_L + \text{h.c.} \quad (3.177)$$

respectively.

First, we can compute the $s_R^d$, by using the constraint associated to $Z \rightarrow b\bar{b}$, $R_b = 0.21629 \pm 0.00066$ that is found in Ref. [41], the width is as follows

$$\Gamma(Z \rightarrow b\bar{b}) = \frac{e^2 (m_Z^2 (m_Z^2 - 4m_b^2))^{1/2}}{288\pi c_W^2 s_W^2 m_Z^2} \times \left( -9c_W^4 m_b^2 + 42c_W^2 s_W^2 m_b^2 
- 54c_W^2 (s_R^d)^2 m_b^2 - 17s_W^2 m_b^2 - 30s_W^2 (s_R^d)^2 m_b^2 - 9(s_R^d)^4 m_b^2 + 9c_W^4 m_Z^2 
+ 6c_W^2 s_W^2 m_Z^2 + 5s_W^4 m_Z^2 + 12s_W^2 (s_R^d)^2 m_Z^2 + 9(s_R^d)^4 m_Z^2 \right) \quad (3.178)$$

then we obtain,

$$0.09 < s_R^d < 0.16 \text{ or } -0.16 < s_R^d < -0.09. \quad (3.179)$$

Now, we used it jointly with (3.170) and $M_B = 2250 GeV$, obtaining

$$0.0002 < s_R^d < 0.0003 \text{ or } -0.0003 < s_R^d < -0.0002. \quad (3.180)$$

After that, we use (3.180) in (3.177), and applying the measurement of the $V_{tb}$ ($tbW$ coupling) given in Ref. [40],

and then we have

$$c_L^u > 0.92, \quad (3.181)$$

which results in the constraint

$$s_L^u < 0.4. \quad (3.182)$$
and for the QCD pair production of $T$, the following interaction is considered

$$\mathcal{L}_{TT} \supset g_s \bar{T}\gamma_\mu T^a \gamma^{a\mu} T,$$

(3.183)

and also we will consider the next interaction

$$\mathcal{L}_{Tt} \supset g_s (f_L \bar{t}_L \gamma_\mu T^a T_L G^{a\mu} T_L + f_R \bar{t}_R \gamma_\mu T^a G^{a\mu} T_R + h.c.),$$

(3.184)

where $g_s f_{L,R}$ are the left- and right-handed couplings between $T$, $t$ and $G$. Similarly for the QCD pair production of $B$, the following interaction is considered

$$\mathcal{L}_{BB} \supset g_s \bar{B}\gamma_\mu B^a \gamma^{a\mu} B,$$

(3.185)

and also we can consider the next interactions

$$\mathcal{L}_{Bb} \supset g_s (g_L \bar{b}_L \gamma_\mu B^a B_L + g_R \bar{b}_R \gamma_\mu B^a G^{a\mu} B_R + h.c.),$$

(3.186)

where $g_s g_{L,R}$ are the left- and right-handed couplings between $B$, $b$ and $G$. Now that we have know the couplings associated for the single production of $T$, we will study the production and decay of this heavy state.
CHAPTER 4

Vector-Like Heavy Quarks at the LHC

In this chapter we will study the production and decay of vector-like quarks, motivated by extensions of the SM where the Higgs is a pNGB. We will focus on quiver theories as well as a model-independent effective Lagrangian approach. In particular, inspired by quiver theories we will add a possible decay mode of the heavy quark into a heavy gluon which has not been considered in the literature. It because the possibility of a first excited state of fermion as in quiver theories can be heavier than the first excited gluon as in Ref. [10]. We will first consider the phenomenology of the quiver theories and comment on the model-independent case, which only requires a rescaling of our results. We will focus on the phenomenology associated to single production of the first excited state of the top quark with left-handed zero mode (we denoted it by $T_L$) through the EW interactions because this mode of production becomes dominant over the pair production at higher masses [12], as saw in Table (3.3) the more relevant couplings were found in the third generation. Considering the following interactions involving $T_L$

$$\mathcal{L}_{g_{T_L}T_L} \supset g_s \bar{T}_L \gamma_\mu T^a g^{\mu,a} T_L, \quad (4.1)$$

$$\mathcal{L}_{GT_{L}L} \supset g_s \bar{T}_L \gamma_\mu T^a G^{\mu,a} (g^L_{T_GL} P_L) t, \quad (4.2)$$

$$\mathcal{L}_{TL_{EW}} \supset - c_{TL_{th}} \bar{T}_L H P_R t + h.c.$$

$$+ c_{T_LbW} \frac{e}{\sqrt{2} s_W} \bar{T}_L \gamma_\mu W^{\mu,+} P_L b + h.c.$$

$$+ c_{T_LZt} \frac{e}{2 s_W c_W} \bar{T}_L \gamma_\mu Z^{\mu} P_L t + h.c., \quad (4.3)$$

where $g^L_{T_GL}$ and $c_{T_Lth}$ are inferred from Tables (3.2) e (3.3), respectively, $G^{\mu,a}$ is the first excited state of the gluon, $H$ is the Higgs boson, $W^{\mu,+}$ and $Z^\mu$ are the massive EW gauge bosons. Now, to find a relation between $c_{TL_{th}}$, $c_{T_LbW}$
and \(c_{T_L Zt}\) we will use the equivalence theorem. Firstly, to obtain a the relation between \(c_{T_L th}\) and \(c_{T_L Zt}\), the widths of \(T_L\) to Higgs-top and Z-top will be assumed to be equal at high energies, for \(m_T \gg m_t, m_h, m_Z\). The \(T_L \to Zt\) partial width is given by

\[
\Gamma_{Zt} = \frac{1}{96\pi m_T^3} (m_t^4 - 2m_t^2 m_{T_L}^2 - 2m_t^2 m_{Z}^2 + m_{T_L}^4 - 2m_{T_L}^2 m_{Z}^2 + m_{Z}^4)^{1/2} \times \\
\left[ \frac{3e^2}{4m_Z^2 c^2 s^2 W} m_t^4 - \frac{3e^2}{2m_Z^2 c^2 s^2 W} m_t^2 m_{T_L}^2 + \frac{3e^2}{4c^2 s^2 W} m_t^2 + \frac{3e^2}{4m_Z^2 c^2 s^2 W} m_{T_L}^4 \right. \\
+ \left. \frac{3e^2}{4c^2 s^2 W} m_{T_L}^2 - \frac{3e^2}{2c^2 s^2 W} m_{Z}^4 \right] (c_{T_L Zt})^2 ,
\]

(4.4)

expanding in powers of \(\frac{m_t}{m_{T_L}}\) or \(\frac{m_{Z}}{m_{T_L}}\), we obtain

\[
\Gamma_{Zt} = \frac{m_{T_L}}{96\pi} \left\{ 1 + \mathcal{O} \left( \frac{m_t}{m_{T_L}} \right)^2 \right\} + \mathcal{O} \left( \frac{m_{Z}}{m_{T_L}} \right) \left\{ \frac{3e^2}{4c^2 s^2 W} \left( \frac{m_t}{m_{T_L}} \right)^2 \right\} - \left. \frac{3e^2}{2c^2 s^2 W} \left( \frac{m_t}{m_{Z}} \right)^2 \right\} + \frac{3e^2}{4c^2 s^2 W} \left( \frac{m_{T_L}}{m_{Z}} \right)^2 \\
+ \frac{3e^2}{4c^2 s^2 W} - \frac{3e^2}{2c^2 s^2 W} \left( \frac{m_{Z}}{m_{T_L}} \right)^2 \right\} (c_{T_L Zt})^2 .
\]

(4.5)

The partial width corresponding to the decay mode of \(T_L\) into \(ht\) is as follows

\[
\Gamma_{ht} = \frac{1}{96\pi m_{T_L}^3} (m_h^4 - 2m_h^2 m_{T_L}^2 - 2m_h^2 m_{T_L}^2 + m_T^4 - 2m_{T_L}^2 m_{T_L}^2 + m_{T_L}^4)^{1/2} \times \\
\left[ -3m_h^2 + 3m_t^2 + 3m_{T_L}^2 \right] (c_{T_L th})^2 ,
\]

(4.6)

this can be expanded in powers of \(\frac{m_h}{m_{T_L}}\) or \(\frac{m_t}{m_{T_L}}\), we obtain

\[
\Gamma_{ht} = \frac{m_{T_L}}{96\pi} \left\{ 1 + \mathcal{O} \left( \frac{m_h}{m_{T_L}} \right)^2 \right\} + \mathcal{O} \left( \frac{m_t}{m_{T_L}} \right) \left\{ \frac{3e^2}{4c^2 s^2 W} \left( \frac{m_t}{m_{T_L}} \right)^2 \right\} \times \\
\left. -3 \left( \frac{m_h}{m_{T_L}} \right)^2 + 3 \left( \frac{m_t}{m_{T_L}} \right)^2 \right\} (c_{T_L th})^2 .
\]

(4.7)

The Goldstone equivalence theorem as in Ref [42] implies that the ratios of the branching fractions of \(T_L \to th, tZ\) and \(W^+ b\) are approximately 1:1:2. Then, for \(m_{T_L} \gg m_h, m_t, m_W\) we have \(\Gamma_{Zt} \simeq \Gamma_{ht}\), which results in a relation between
\[ \frac{e}{2c_W s_W} \left( \frac{m_{T_L}}{m_Z} \right) c_{T_L Z t} = c_{T_L t h}. \] (4.8)

In addition, to obtain the relation between \( c_{T_L Z t} \) and \( c_{T_L b W} \), we write the \( T_L \to W^+ b \) partial width,

\[
\Gamma_{W^+ b} = \frac{1}{96\pi m_{T_L}^2} \left[ \left( m_b - 2m_{T_L}^2 - 2m_{W}^2 + m_{T_L}^2 - 2m_{T_L}^2 m_W + m_{W}^2 \right)^{1/2} \times \right.
\frac{3e^2}{2s_W^2} m_b^2 + \frac{3e^2}{2s_W^2} m_{T_L}^2 - 3e^2 m_{W}^2 m_{T_L}^2
\left. + \frac{3e^2}{2s_W^2} m_{T_L}^2 - \frac{3e^2}{s_W^2} m_W^2 \right] (c_{T_L b W})^2. \] (4.9)

In an analogous way to the previous expansion (4.6), but now expanding in powers of \( \frac{m_W}{m_{T_L}} \) or \( \frac{m_b}{m_{T_L}} \), we obtain

\[
\Gamma_{W^+ b} = \frac{m_{T_L}}{96\pi} \left[ 1 + \mathcal{O} \left( \left( \frac{m_b}{m_{T_L}} \right)^2 \right) + \mathcal{O} \left( \left( \frac{m_W}{m_{T_L}} \right)^2 \right) \right] \left[ \frac{3e^2}{2s_W^2} \left( \frac{m_b}{m_{T_L}} \right)^2 \right.
\frac{3e^2}{2s_W^2} \left( \frac{m_b}{m_{T_L}} \right)^2 - \frac{3e^2}{s_W^2} \left( \frac{m_b}{m_W} \right)^2
\left. + \frac{3e^2}{2s_W^2} \left( \frac{m_{T_L}}{m_W} \right)^2 - \frac{3e^2}{s_W^2} \left( \frac{m_W}{m_{T_L}} \right)^2 \right] (c_{T_L b W})^2. \] (4.10)

Again we use the equivalence theorem to establish the relation between \( c_{T_L Z t} \) and \( c_{T_L b W} \), imposing that \( \Gamma_{Z t} \simeq \frac{1}{2} \Gamma_{W^+ b} \), which results in

\[
\frac{1}{c_W} \left( \frac{m_W}{m_Z} \right) c_{T_L t Z} = c_{T_L b W}. \] (4.11)

Notice that the coupling \( c_{T_L t h} = Y_{T_L t h} \), where \( Y_{T_L t h} / \sqrt{2} \) is inferred from the third column in Table (3.3). Using (4.7), (4.8), we can study the EW single \( T_L \) production for instance at the LHC. Figure (4.1) shows the single production of \( T_L \) through fusion of \( W b \), i.e., involving \( c_{T_L b W} \). We will consider both the model-independent case as well as the case of quiver theories. On the one hand we will consider the couplings given in Ref. [42], here we point out that \( c_{T_L b W} \) is actually \( \sin \theta_L^u \) mentioned in Subsection (3.2.1), for the study of the single production of the heavy fermion. On the other hand, from the quiver theory the couplings given in Table (3.3) will be also considered. According to quiver theories, once we fix
the parameters, e.g., $N$, $v_1$ and $v_N$, we are ready to compute all the couplings of
the excited fermions, relevant for their production and decay at the LHC. In the
next section we consider the pair production and the single production of $T_L$.

4.1 Heavy $T_L$ Production at LHC

In this section, we consider $T_L$ production. On the one hand, there is a heavy
quark pair production via QCD, where these pairs come from quark-antiquark
and gluon-gluon fusion [43, 44]. On the other hand, we consider the single pro-
duction channel of $T_L$ via the $Wb$ EW fusion. This production mode is shown
in Figure (4.1).

We computed the pair and single $T_L$ production cross section at the LHC
with $s = \sqrt{13}$ by using MadGraph [15]. The first production mode is model-
independent since is just QCD pair production. Figure (4.2) shows these produc-
tion modes as a function of $m_{T_L}$. We considered the single production channel
of $T_L$ via the $W$ exchange process $pp \to T_Lb\bar{j}$ as can be seen in the top panel of
Figure (4.2), the black line shows the pair production of $T_L$ via QCD, whereas
the other lines correspond to the single production for fixed values of the cou-
plings $c_{T_LbW} \lesssim 0.4$ as considered in Ref. [42]. It shows that the single production
dominate for $m_{T_L}$ greater than 1 TeV.

Also, the $T_L$ production as a function of the mass of $T_L$ in quiver theories
was computed. As shown in the bottom panel of Figure (4.2), the pair $T_L pro-
duction is the same as in the top panel case. While, the single production cross section is given for the cases N=4 and N=15 by the medium turquoise and dark turquoise lines, respectively. It is shown that the pair production dominates for $m_{T_L}$ masses below 1 TeV for both cases N=4 and N=15; however the single production dominates for $m_{T_L}$ greater than 1 TeV and 3.9 Tev for N=15 and N=4 respectively.

4.2 Analysis Heavy $T_L$ Decay Modes

Here, we examine the $T_L$ decay to the Higgs sector and the additional way in which $T_L$ can decay, i.e., the decay mode $T_L \to Gt$, where $G$ the color-octet. To study the contribution of $G$ to the signal, we will first compute the mass difference between $T_L$ and $G$, i.e. $\Delta m$, for quiver models couplings. In order to have comparable branching ratios, the following condition is required

$$\Gamma_{W^+b} \lesssim \Gamma_{Gl},$$

where $\Gamma_{Gl}$ is the $T_L \to Gt$ partial width and is given by

$$\Gamma_{Gl} = \frac{1}{24\pi m_G^2 m_{T_L}^3} \left( m_G^4 - 2m_G^2 m_t^2 - 2m_G^2 m_{T_L}^2 + m_t^4 - 2m_t^2 m_{T_L}^2 + m_{T_L}^4 \right)^{1/2} \times$$

$$\left[ m_{T_L}^4 + m_G^2 m_t^2 - 2m_G^4 + m_G^2 m_{T_L}^2 + m_t^4 - 2m_t^2 m_{T_L}^2 \right] (g_{T_L Gt})^2.$$  \hspace{1cm} (4.13)

We consider quiver models with $N = 4(15)$, with couplings $g_{T_L Gt} = 0.85(0.83)$ and $Y_{tLHt} = 0.028(0.352)$, respectively. Notice that the coupling $c_{T_L Ht} = Y_{tLHt}/\sqrt{2}$. Now, we can substitute (4.9), (4.13) in (4.12) and considering $G$ mass to be 2 TeV, and then, after solving for $m_{T_L}$, the mass differences are listed in Table (4.1).

| $N$ | $m_G$ [GeV] | $\text{min } m_{T_L}$ [GeV] | $\Delta m$ |
|-----|-------------|----------------------------|-----------|
| 4   | 2000        | 2172                       | 172       |
| 15  | 2000        | 2278                       | 279       |

Table 4.1. Masses involved in the decay modes of $T_L$ to the color-octet and EW sector for $N = 4, 15$.

From the information of the bottom panel of Figure (4.2) and Table (4.1), we conclude that to produce a heavy $T_L$ decaying to $G$ with reasonable branching ratio, we must consider the single production as the dominant channel for $N = 15$. 
Figure 4.2. Cross sections for QCD pair and single production for $T_L$ at LHC with $\sqrt{s} = 13$ TeV as a function of $m_{T_L}$. For fixed values of $c_{T_L bW}$ (top panel) and couplings from quiver theories with $N = 4, 15$ (bottom panel). In the later $c_{T_L h t}$ was inferred from the third column in Table (3.3) and $c_{T_L bW}$ vary according to (4.8) and (4.13) with respect to the $T_L$ mass.
4.3 Prospects for the LHC

The previous section has shown that according to the condition (4.12), it is possible to study the case where both decay modes are comparable. The decay modes into the Higgs and EW gauge bosons were studied in the literature [37, 38, 42, 46]. Here, we will concentrate on the decay mode $T_L \rightarrow Gt$. We will consider both the $N = 15$ quiver theory as well as the model-independent case. We opted as signal process the production of that heavy top decaying into $G$, which afterwards decay into a pair of bottom quarks, i.e. $pp \rightarrow T_L b_j \rightarrow Gtb_j \rightarrow b\bar{b}Wbj$. To study the feasibility of detecting the signal we consider the example of single top production $pp \rightarrow tbj \rightarrow Wbbj$ as a background, this simple background was considered to estimate the required luminosity for the discovery of our signal. The couplings considered in for our signal were based on quiver theories with $N = 15$ and the masses were chosen to be $m_T$ and $m_G$ as 2.27 and 2 TeV, respectively. The cross sections both for signal and background were computed at $\sqrt{s} = 13$ TeV pp collider jointly with a cut given by $H_T > 500$ GeV (similar to Ref. [42]), where $H_T$ is the total transverse hadronic energy and defined by

$$H_T = \sum_{\text{hadronic particles}} \|\mathbf{p_T}\|,$$

where $\mathbf{p_T}$ is the transverse momentum.

Thus, considering this cut we simulated 50K and 500K events for signal and background, respectively. To generate the events, the chain MadGraph [45]-Pythia [47]-Delphes [48] was used. After that, the comparison between the signal and background distributions was obtained by using Madanalysis (ma5) [49, 50, 51]. The baseline luminosity was assumed to be 1 $ab^{-1}$. Then, we implemented other kinematic cuts on the events as can be seen in Table (4.2). It shows a summary of the results of applying simple kinematic cuts, the selected cuts were inferred sequentially according to the kinematic distributions showed in Figures (4.3), (4.4), and (4.5). We considered the Fastjet algorithm anti-kt with $\Delta R = 0.6$ interfaced in ma5. For details of the recombination algorithm anti-kt see [52].

For the first selection after generating events, we took into account the number of jets distributions as shown in Figure (4.3). To compare the shapes of the curves related to both background and signal datasets, the events were normalized to unity. We select the following cut

$$N_j > 6,$$
Table 4.2. Best cut-flow analysis obtained with ma5. Notice that a generator cut of $H_T > 500$ GeV was applied. Fastjet algorithm anti-kt with $\Delta R = 0.6$.

|                  | Signal     | SM single top |
|------------------|------------|---------------|
| Cross section    | $5.2 \times 10^{-5}$ pb | 0.2 pb |
| Events before cuts | 50K a.u.  | 500K a.u.     |
| $N_j > 6$       | 19952      | 51112         |
| $H_T > 800$ GeV | 18272      | 22290         |
| $p_T,j_1 > 400$ GeV | 14231      | 7408          |
| Reco. Eff.      | 0.28       | $1.48 \times 10^{-2}$ |

Figure 4.3. Number of jets distributions for events normalized to unity before any cuts.

where $N_j$, is the number of jets. Figure (4.4) shows the total transverse hadronic energy of jets distributions after the selection (4.15). To obtain this plot the events also were normalized to unity. So a good discrimination between signal and background can be obtained by using the following cut

$$H_T > 800 \text{ GeV}. \quad (4.16)$$
4.3 Prospects for the LHC

Figure 4.4. Total transverse hadronic energy of jets distributions for events normalized to unity after the selection $N_j > 6$.

Figure 4.5. Transverse-momentum of the hardest jet distributions for events normalized to unity after the selection $H_T > 800$ GeV.
After these cuts, we also considered the transverse-momentum of the hardest jet distributions for events as shown in Figure (4.5), in such a way that to compare both signal and background distributions the events were also normalized to unity in this plot. Then, we select

$$p_{T,j_1} > 400 \text{ GeV},$$

where \(p_{T,j_1}\) is the transverse-momentum of the hardest jet.

Now, from the values in Table (4.2), we are able to estimate the amount of luminosity that we need in order to have 5\(\sigma\) discovery. To estimate the required luminosity for 5\(\sigma\) we impose that \(S/\sqrt{B} \geq 5\), where \(S\) and \(B\) are the number of events after cuts, which scale linearly with the luminosity. Then the previous requirement can be written as,

$$L \geq 25 \frac{\sigma_B \times \epsilon_B}{\sigma_S \times \epsilon_S^2},$$

where \(\sigma_B\) and \(\sigma_S\) are the background and signal cross sections, respectively. In (4.18) we also have that \(\epsilon_B\) and \(\epsilon_S\) are the efficiencies after cuts (these are given in the last row of Table (4.2)) for the background and signal, respectively. Then substituting the numerical values in (4.18), we have

$$\geq 25 \frac{0.2 \times 1.48 \times 10^{-2}}{(5.2 \times 10^{-5} \times 0.28)^2} \times \frac{1}{1000} \text{ fb}^{-1},$$

$$\geq 7.4 \times 10^{-5} \text{ fb}^{-1},$$

$$\geq 3.52 \times 10^5 \text{ fb}^{-1} (352 \text{ ab}^{-1}).$$

Clearly, this number is too big to be achieved by the LHC, for these parameters the LHC will not be sensitive to quiver theories for high masses of the vector-like quarks.

On the other hand, we can estimate the reach of the model-independent scheme presented in Section (3.2). For instance, rescaling the calculations above, this is due to the main channel for the signal is proportional to \(c_{TLWb}^2\), so we have that

$$L \geq 25 \frac{\sigma_B \times \epsilon_B}{\sigma_S \times \epsilon_S^2} \times \left(\frac{0.027}{c_{TLWb}}\right)^4,$$

where 0.027 was the value of \(c_{TLWb}\) for \(N = 15\). Now, we can see that a 5\(\sigma\) discovery can be achieved with the following values of the parameters: \(c_{TLWb} \geq 0.16\) for 300\(fb^{-1}\), \(c_{TLWb} \geq 0.12\) for 1000\(fb^{-1}\) and \(c_{TLWb} \geq 0.09\) for a High-Luminosity
Large Hadron Collider (HL-LHC) with $3000 \, fb^{-1}$.

The objects considered are too heavy, such that one possibility to study these kind of particles will be consider pp colliders, at high energies, for instance at $\sqrt{s} = 100$ TeV.
CHAPTER 5

Vector-Like Heavy Quarks at High Energy Colliders

As we saw in chapter 4 the LHC will not be sensitive for vector-like quark masses $\gtrsim 2\text{TeV}$ in quiver theories. And after estimating the coupling between the heavy top, bottom quark with W gauge boson in a model-independent approach, we concluded that more energy was need in cases where couplings are smaller than 0.09 and with large vector-like quark masses ($> 2\text{ TeV}$). Here we look at a hypothetical pp collider with $\sqrt{s} = 100\text{ TeV}$. Other center-of-mass energies are being considered, such as 27 TeV at the LHC tunnel.

Just as in the previous chapter we use as benchmark the case of the Vector-like quark $SU(2)$-singlet up-type, $T$, in the case where it is coupled to a heavy gluon $G$, such that $T$ can decay into $Gt$ with subsequent decays of $G$ into a pair of bottom or top quarks. The electroweak decays of $T$ obey the approximate relations,

$$\Gamma(T \rightarrow Ht) \simeq \Gamma(T \rightarrow Zt) \simeq \frac{1}{2} \Gamma(T \rightarrow W^+b),$$  \hspace{1cm} (5.1)

as seen in [42].

Although extensive research has been carried out on the EW channels: $T \rightarrow (H, Z)t$ and $T \rightarrow (b_L, W^+)$, no study of the $T \rightarrow Gt$ channel was done, we will focus on it. We will take into account that the interactions between $T$, $t$ and $G$ as well as $b$ and $G$ are through the qcd coupling.

We considered as signal process the single $T$ production, such that $T$ decays into $Gt$ with subsequent decays of $G$ into a quark pair of $b$ and the quark $t$ decaying semi-leptonically. We took into account the couplings indicated in Section [3.2] and the masses were chosen for $T$ and $G$ as 2.3 and 2 TeV, respectively.

At this high energies it is still true that the single-$T$ production is dominant over the pair production, as seen in Figure [5.1]. Even for small values of $\sin\theta_u^L$ such
as 0.1, single-$T$ production dominates for $m_T > 2.2$ TeV, at this point of $m_T$ jointly with $\sin \theta^L_u = 0.1$, the corresponding value of the Yukawa coupling is

$$Y^u_{34} = 1.315,$$

(5.2)

it is obtained by using the relations (3.154) and (3.150). The maximum value of the coupling $\sin \theta^L_u$ comes from the relation (3.159), and the maximum Yukawa coupling is given in the second row of Table (5.1), this would still be perturbative. Table (5.1) shows the Yukawa couplings that were obtained by using the allowed values of $\sin \theta^L_u$ according to (3.159) as well as the relations given in (3.150), (3.154) and considering the same mass for $T$ indicated above.

| $\sin \theta^L_u$ | $Y^u_{34}$ |
|-----------------|-----------|
| 0.4             | 5.25      |
| 0.3             | 3.94      |
| 0.2             | 2.63      |
| 0.1             | 1.31      |

Table 5.1. Values of the Yukawa coupling $Y^u_{34}$ for $m_T = 2.3$ TeV as a function of $\sin \theta^L_u$. 

Figure 5.1. Cross section for single and pair $T$ production at 100 TeV pp collider, as a function of the $T$ mass.
The vector-like heavy quark pair production via QCD was considered, where these pairs come from quark-antiquark and gluon-gluon fusion. The pair production dominates for $T$ masses below 0.8 TeV for $T$ as a Vector-like $SU(2)$-singlet; however the single production dominates for $m_T$ greater than 1 TeV, as shown in Figure 5.1.

The widths and branching ratios of $T$ for the maximum value of $\sin \theta^L_u$ are shown in Table 5.2. The branching ratios of $T$ to the EW sector are higher, of which the decay of $T$ into a $W^+$ boson and a $b$ quark provides easily the most proportion. Less than 1 percent of branching ratio consists of the heavy gluon mode.

\[
\begin{array}{|c|c|c|}
\hline
m_T = 2300 \text{ [GeV]} & \Gamma_T \text{ [GeV]} & Br \\
\hline
\Gamma(T \rightarrow W^+ b) & 638.8 & 0.54 \\
\Gamma(T \rightarrow Ht) & 276.2 & 0.23 \\
\Gamma(T \rightarrow Zt) & 265.8 & 0.22 \\
\Gamma(T \rightarrow Gt) & 4.3 & 0.005 \\
\hline
\end{array}
\]

Table 5.2. Decays of $T$ to the EW sector and the heavy gluon mode in units of GeV for $m_T = 2.3 \text{ TeV}, \sin \theta^L_u = 0.4$ and $m_G = 2 \text{ TeV}$.

We investigate whether the heavy gluon mode can be observed at this higher energies. Branching ratios are similar for other values of $\sin \theta^L_u$, as can be seen in Tables 5.3, 5.4 and 5.5. Similar results have been found for the branching ratios corresponding to the EW mode. However, for the heavy gluon mode its branching ratio increases with the decreases of $\sin \theta^L_u$. For instance, for $\sin \theta^L_u = 0.1$ the EW widths are lower when compared to the other cases, this is because the EW widths are increasing with $\sin \theta^L_u$.

\[
\begin{array}{|c|c|c|}
\hline
m_T = 2300 \text{ [GeV]} & \Gamma_T \text{ [GeV]} & Br \\
\hline
\Gamma(T \rightarrow W^+ b) & 359.3 & 0.52 \\
\Gamma(T \rightarrow Ht) & 167.1 & 0.24 \\
\Gamma(T \rightarrow Zt) & 160.8 & 0.23 \\
\Gamma(T \rightarrow Gt) & 6.4 & 0.009 \\
\hline
\end{array}
\]

Table 5.3. Decays of $T$ to the EW sector and the heavy gluon mode in units of GeV for $m_T = 2.3 \text{ TeV}, \sin \theta^L_u = 0.3$ and $m_G = 2 \text{ TeV}$.
\[ m_T = 2300 \text{ [GeV]} \]

| Decay | \( \Gamma \) [GeV] | \( \text{Br} \) |
|-------|-----------------|----------------|
| \( T \rightarrow W^+b \) | 159.7 | 0.50 |
| \( T \rightarrow Ht \) | 78.3 | 0.25 |
| \( T \rightarrow Zt \) | 75.4 | 0.24 |
| \( T \rightarrow Gt \) | 6.4 | 0.02 |

**Table 5.4.** Decays of \( T \) to the EW sector and the heavy gluon mode in units of GeV for \( m_T = 2.3 \text{ TeV} \), \( \sin \theta_L = 0.2 \) and \( m_G = 2 \text{ TeV} \).

\[ m_T = 2300 \text{ [GeV]} \]

| Decay | \( \Gamma \) [GeV] | \( \text{Br} \) |
|-------|-----------------|----------------|
| \( T \rightarrow W^+b \) | 39.9 | 0.46 |
| \( T \rightarrow Ht \) | 20.2 | 0.23 |
| \( T \rightarrow Zt \) | 19.4 | 0.23 |
| \( T \rightarrow Gt \) | 6.4 | 0.07 |

**Table 5.5.** Decays of \( T \) to the EW sector and the heavy gluon mode in units of GeV for \( m_T = 2.3 \text{ TeV} \), \( \sin \theta_L = 0.1 \) and \( m_G = 2 \text{ TeV} \).

### 5.1 Prospects for Future pp Colliders

In this section a different approach that showed in Section 4.3 will be considered, this due to the use of \( \sqrt{s} = 100 \text{ TeV} \) pp collider and different relations to that considered in (4.12), for instance, as shown in Table (5.2), the widths of \( T \) to the EW sector are considerably higher than the heavy gluon mode. To study this latter mode of decay at \( \sqrt{s} = 100 \text{ TeV} \) pp collider, the signal is \( pp \rightarrow T\bar{b}j \rightarrow G\bar{t}bj \rightarrow b\bar{b}W^+bbj \rightarrow b\ell\nu bbbj \) and the backgrounds considered are \( pp \rightarrow W^\pm bbbbj \rightarrow l\ell bbbbj \) and \( pp \rightarrow t\bar{b}bb \rightarrow l\ell bbb \). We do not consider \( \tau \) leptons in the final state because they are harder to identify. The cross sections for the signal and backgrounds were computed at \( \sqrt{s} = 100 \text{ TeV} \) pp collider. We simulated 100K events for signal as well as backgrounds, these were obtained by using MadGraph. These events were analyzed in Madanalysis, and then the efficiencies were obtained. Simple cuts were applied as can be seen in Table (5.6), which shows a summary of the results. The events before cuts were normalized to 3000 \( fb^{-1} \) of luminosity.

Firstly, considering \( \sin \theta_L = 0.4 \), we implemented kinematic cuts on the events as can be seen in Table (5.6). It shows a summary of the results of applying simple kinematic cuts, inferred sequentially according to the kinematic distributions showed in Figures (5.2) and (5.3).
5.1 Prospects for Future pp Colliders

|                      | Signal | $W^+bbbj$ | $tbjbb$ | Significance |
|----------------------|--------|-----------|---------|--------------|
| $\sigma [pb]$        | 0.0219 | 13.69     | 5.528   | $S/\sqrt{B}$ |
| Events before cuts   | 65700  | 41070000  | 16584000| 9            |
| $M_{j1,j2} > 1900.0$ GeV | 56607.1| 888344   | 459708  | 49           |
| $H_T > 2200.0$ GeV   | 42641  | 31213     | 8623.7  | 214          |

Table 5.6. Sequence of cuts analyzed in ma5 for $\sin\theta_u^L=0.4$.

![Figure 5.2](image)

**Figure 5.2.** The invariant mass distribution for the two more energetic jets for the signal with $m_{T,G} = 2.3$, 2 TeV, $\sin\theta_u^L = 0.4$, and the $W^+bbbj$ and $tbjbb$ backgrounds before cuts.

For the first selection in Table (5.6) after generated events, we took into account the invariant mass distribution for the two more energetic jets as shown in Figure (5.2). To compare the shapes of the curves related to both background and signal datasets, the events were normalized to unity. We select the following cut

$$M_{j1,j2} > 1900.0 \text{ GeV},$$

(5.3)

where $M_{j1,j2}$ is the invariant mass of the two more energetic jets. Figure (5.3) shows the distributions of the total transverse energy in jets, $H_T$ after the selection (5.3). To obtained this plot the events also were normalized to unity. So a good discrimination between signal and background can be obtained by using the following cut

$$H_T > 2200.0 \text{ GeV},$$

(5.4)
Figure 5.3. The transverse hadronic energy distribution for the signal with \( m_{T,G} = 2.3, \) 2 TeV, \( \sin \theta_L = 0.4, \) and the \( W^{+}b\bar{b}bj \) and \( t\bar{b}jbb \) backgrounds after the selection \( M_{j_{1}j_{2}} > 1900.0 \) GeV.

Now, assuming 70\% \textit{b}-tagging efficiency, and then considering 4 \textit{b} tags the significance will be

\[
S/\sqrt{B} \approx 50. \tag{5.5}
\]

Secondly, considering \( \sin \theta_L = 0.3, \) we implemented kinematic cuts on the events as can be seen in Table (5.7). It shows a summary of the results of applying simple kinematic cuts, the selected cuts were inferred sequentially according to the kinematic distributions showed in Figures (5.4) and (5.5).

\[ \begin{array}{|c|c|c|c|}
\hline
\sigma [\text{pb}] & \text{Signal} & W^{+}b\bar{b}bj & tbjbb & S/\sqrt{B} \\
\hline
\text{Events before cuts} & 47850 & 41070000 & 16584000 & 6 \\
\hline
M_{j_{1}j_{2}} > 1800 \text{ GeV} & 42706.6 & 1004161 & 518415 & 35 \\
\hline
H_T > 2000 \text{ GeV} & 34090.7 & 50926 & 12935 & 135 \\
\hline
\end{array} \]

Table 5.7. Sequence of cuts analyzed in ma5 for \( \sin \theta_L = 0.3. \)

For the first selection in Table (5.6) after generated events, we took into account the invariant mass distribution for the two more energetic jets as shown in Figure (5.4). To compare the shapes of the curves related to both background and signal datasets, the events were normalized to unity. We select the following cut

\[
M_{j_{1}j_{2}} > 1800.0 \text{ GeV}. \tag{5.6}
\]
Figure 5.4. The mass distribution for the two more energetic jets for the signal with $m_{T,G} = 2.3, 2$ TeV, $\sin \theta_u = 0.3$, and the $W^+bb\bar{b}j$ and $tbj\bar{b}$ backgrounds before cuts.

Figure (5.5) shows the distributions of the total transverse energy in jets after the selection $M_{j1j2} > 1800$ GeV. To obtained this plot the events also were normalized to...
unity. So a good discrimination between signal and background can be obtained by using the following cut

\[ H_T > 2000.0 \text{ GeV}, \quad (5.7) \]

Now, assuming 70% \(b\)-tagging efficiency, and then considering 4 \(b\) tags the significance will be

\[ \frac{S}{\sqrt{B}} \simeq 30. \quad (5.8) \]

Following this, considering \(\sin \theta_L^L = 0.2\), we implemented kinematic cuts on the events as can be seen in Table (5.8). It shows a summary of the results of applying simple kinematic cuts, the selected cuts were inferred sequentially according to the kinematic distributions showed in Figures (5.6) and (5.7).

![Figure 5.6](image-url)

**Figure 5.6.** The mass distribution for the two more energetic jets for the signal with \(m_{T,G} = 2.3, 2 \text{ TeV}, \sin \theta_L^L = 0.2\), and the \(W^{+}b\bar{b}b\bar{b}j\) and \(t\bar{b}j\bar{b}b\) backgrounds before cuts.

|                | Signal  | \(W^{+}b\bar{b}b\bar{b}j\) | \(tb\bar{b}b\) | Significance |
|----------------|---------|-----------------------------|----------------|--------------|
| \(\sigma [pb]\) | 0.009938 | 13.69                       | 5.528          | \(S/\sqrt{B}\) |
| Events before cuts | 29814   | 41070000                    | 16584000       | 4            |
| \(M_{j1j2} > 1800 \text{ GeV} \) | 25922.4 | 1004161                     | 518415         | 21           |
| \(H_T > 1800 \text{ GeV} \)    | 21132.2 | 70229                       | 17744          | 71           |

**Table 5.8.** Sequence of cuts analyzed in ma5 for \(\sin \theta_L^L = 0.2\).
For the first selection in Table (5.8) after generated events, we took into account the invariant mass distribution for the two more energetic jets as shown in Figure (5.6). To compare the shapes of the curves related to both background and signal datasets, the events were normalized to unity. We select the following cut

\[ M_{j_1j_2} > 1800.0 \text{ GeV}. \] (5.9)

Figure (5.7) shows the distributions of the total transverse energy in jets after the selection (5.9). To obtain this plot, the events also were normalized to unity. So a good discrimination between signal and background can be obtained by using the following cut

\[ H_T > 1800.0 \text{ GeV}, \] (5.10)

Figure 5.7. The transverse hadronic energy distribution for the signal with \( m_{T,G} = 2.3, 2 \text{ TeV}, \sin \theta_L^u = 0.2 \), and the \( W^+ b\bar{b}bj \) and \( t\bar{b}j\bar{b}b \) backgrounds after the selection \( M_{j_1j_2} > 1800 \text{ GeV} \).

Now, assuming 70% \( b \)-tagging efficiency, and then considering 4 \( b \) tags the significance will be

\[ \frac{S}{\sqrt{B}} \simeq 17. \] (5.11)

Finally, considering \( \sin \theta_L^u = 0.1 \), we implemented kinematic cuts on the events as can be seen in Table (5.9). It shows a summary of the results of apply sim-
ple kinematic cuts, the selected cuts were inferred sequentially according to the kinematic distributions showed in Figures (5.8) and (5.9).

|          | Signal | $W^{+}b\bar{b}bj$ | $t\bar{b}jjb$ | Significance |
|----------|--------|------------------|----------------|--------------|
| $\sigma[\text{pb}]$ | 0.005148 | 13.69 | 5.528 | $S/\sqrt{B}$ |
| Events before cuts | 15443 | 41070000 | 16584000 | 2 |
| $M_{j_1j_2} > 1850$ GeV | 12313.5 | 946663 | 486076 | 10 |
| $H_T > 1700$ GeV | 9455.1 | 75979 | 19734 | 31 |

Table 5.9. Sequence of cuts analyzed in ma5 for $\sin \theta_L^u=0.1$.

For the first selection in Table (5.9) after generated events, we took into account the invariant mass distribution for the two more energetic jets as shown in Figure (5.8). To compare the shapes of the curves related to both background and signal datasets, the events were normalized to unity. We select the following cut

$$M_{j_1j_2} > 1850.0 \text{ GeV}. \quad (5.12)$$

![Figure 5.8](image)

**Figure 5.8.** The mass distribution for the two more energetic jets for the signal with $m_{T,G} = 2.3$, 2 TeV, $\sin \theta_L^u = 0.1$, and the $W^{+}b\bar{b}bj$ and $t\bar{b}jjb$ backgrounds before cuts.

Figure (5.9) shows the distributions of the total transverse energy in jets after the selection $(5.12)$. To obtained this plot the events also were normalized to unity. So a good discrimination between signal and background can be obtained.
by using the following cut

\[ H_T > 1700.0 \text{ GeV}, \quad (5.13) \]

\[ \text{Figure 5.9.} \quad \text{The transverse hadronic energy distribution for the signal with } m_{T,G} = 2.3, 2 \text{ TeV}, \sin \theta^L_u = 0.1, \text{ and the } W^+bb\bar{b}j \text{ and } t\bar{b}j\bar{b} \text{ backgrounds after the selection } M_{j_1j_2} > 1850 \text{ GeV.} \]

Now, assuming 70% \( b \)-tagging efficiency, and then considering 4 \( b \) tags the significance will be

\[ \frac{S}{\sqrt{B}} \approx 7. \quad (5.14) \]

For more realistic simulation we would like to consider as background the case where the involving final state has 5 jets jointly with e\(^-\)\(\nu\) or \(\mu^-\)\(\nu\). In addition that, for futures studies we can consider the EW decay modes to study the phenomenology at high energy colliders.

We do not have different kinematic cuts for each different values of \( \sin \theta^L_u \), that is the sequence of cuts implemented as in Table (5.9) should be more than adequate. The ratio \( \frac{S}{\sqrt{B}} \) is large enough for \( \sin \theta^L_u = 0.1 \) to be promising for larger \( m_T \) and smaller values of \( \sin \theta^L_u \), this work is in progress.

For more realistic study, we need to simulate more backgrounds. But looks promising.
Also, we need to add pile-up effect, it is still unknown for future machine, we do not know machine parameters, but can guess that pile-up is large.

Ultimately, it looks like $\sqrt{s} = 100$ TeV pp collider is how we will be able to study a new sector of vector-like quarks with large masses in detail.
CHAPTER 6
Conclusions and Outlook

Extensions of the SM that solve the hierarchy problem by having the Higgs as a pNGB typically must contain new vector-like quarks. In this thesis are studied the phenomenology of vector-like quarks in two such theories: quiver theories and a model-independent effective theory of vector-like quarks. In the case of quiver theories we computed the spectrum and couplings of vector-like quarks as well as excited gauge bosons to SM states, particularly $W^\pm$, $Z$ and the Higgs. In the last case we needed to formulate the Higgs as a pNGB in the quiver theory. Once we obtained the spectrum and its couplings we started studying the phenomenology of vector-like quarks at the LHC. We saw that for quiver theories the production cross section are dominated by the single $T$ channel, is too small even for the HL-LHC. The reason was a combination of the small $T W b$ coupling and the large value of $m_T$, the vector-like quark mass.

For the model-independent approach we concluded that the LHC could discover the $T \rightarrow G t$ decay channel with 300 $fb^{-1}$ if $c_{T W b} > 0.16$, and for 3000 $fb^{-1}$ (the ultimate HL-LHC luminosity) if $c_{T W b} > 0.09$. Thus is clear that for $m_T \gtrsim 2\text{TeV}$, quiver theories uses $c_{T W b} \simeq 0.03$, are out of reach of the LHC.

The results of chapter 4 indicated that in order to study the $T \rightarrow G t$ in quiver theories for $m_T > 2\text{TeV}$ higher center-of-mass energies are needed. In chapter 5 we started a study of this channel for a hypothetical pp collider with $\sqrt{s} = 100$ TeV. We studied the signal to background significance after cuts for various values of the coupling responsible for single $T$ production. As a first pass, we used $pp \rightarrow W^+ b b b bj \rightarrow l\nu b b b bj$, and $pp \rightarrow t b j b b \rightarrow l\nu b b j b b$ as background.

We conclude that for $\sqrt{s} = 100$ TeV $5\sigma$ discoveries will be accessible for couplings well below 0.1, other possible.

In the future a more complete background study will be needed. Furthermore,
there is a need to include the effects of pile-up which were not considered here. We can see that if the discoveries of the LHC point to the possibility of heavy vector-like quarks, high energy pp colliders could study these sector in detail.

Wave-Function of Excited States

An specific example for hypothetical fermion with left-handed zero mode and localization parameter $c_L = 0.2$, in this case the left-handed zero mode is localized toward the N-th site, we show their Wave-Functions in Figures A.1, A.2 and A.3 for $N = 4$, $N = 9$ and $N = 15$ respectively.

Figure A.1: Wave-Functions of hypothetical fermion with left-handed zero mode and localization parameter $c_L = 0.2$, where $j$ is a index of site and $n$ is a index of Kaluza-Klein mode. In this case $N = 4$ and some allowed $n$ are shown. For the visualization, we choose by the opposite signs of $h^{j,1}_L$ and $h^{j,2}_L$. 
Figure A.2: Wave-Functions of hypothetical fermion with left-handed zero mode and localization parameter $c_L = 0.2$, where $j$ is a index of site and $n$ is a index of Kaluza-Klein mode. In this case $N = 9$ and some allowed $n$ are shown. For the visualization, we choose by the opposite sign of $h_L^{j,n}$.

Figure A.3: Wave-Functions of hypothetical fermion with left-handed zero mode and localization parameter $c_L = 0.2$, where $j$ is a index of site and $n$ is a index of Kaluza-Klein mode. In this case $N = 15$ and some allowed $n$ are shown.
Figure A.4: Wave-Functions zero mode $h_R^{j,0}$, first mode $h_R^{j,1}$ of bottom fermion with right-handed zero mode and localization parameter $c_R = -0.61$, and Wave-Function first mode of gauge boson $f^{j,1}$ where $j$ is a index of site and $n$ is a index of Kaluza-Klein mode. In this case $N = 4$ and some allowed $n$ are shown. For the visualization, we choose by the opposite sign of $h_R^{j,0}$.

Figure A.5: Wave-Functions zero mode $h_R^{j,0}$, first mode $h_R^{j,1}$ of bottom fermion with right-handed zero mode and localization parameter $c_R = -0.61$, and Wave-Function first mode of gauge boson $f^{j,1}$ where $j$ is a index of site and $n$ is a index of Kaluza-Klein mode. In this case $N = 15$ and some allowed $n$ are shown.
Figure A.6: Wave-Functions zero mode \( h_{L}^{j,0} \), first mode \( h_{L}^{j,1} \) of top fermion with left-handed zero mode and localization parameter \( c_{L} = 0.51 \), and Wave-Function first mode of gauge boson \( f^{j,1} \) where \( j \) is a index of site and \( n \) is a index of Kaluza-Klein mode. In this case \( N = 4 \) and some allowed \( n \) are shown. For the visualization, we choose by the opposite sign of \( h_{L}^{j,0} \).

Figure A.7: Wave-Functions zero mode \( h_{L}^{j,0} \), first mode \( h_{L}^{j,1} \) of top fermion with left-handed zero mode and localization parameter \( c_{L} = 0.51 \), and Wave-Function first mode of gauge boson \( f^{j,1} \) where \( j \) is a index of site and \( n \) is a index of Kaluza-Klein mode. In this case \( N = 15 \) and some allowed \( n \) are shown.
Figure A.8: Wave-Functions zero mode $h_{R}^{j,0}$, first mode $h_{R}^{j,1}$ of top fermion with right-handed zero mode and localization parameter $c_{R} = -0.12$, and Wave-Function first mode of gauge boson $f^{j,1}$ where $j$ is a index of site and $n$ is a index of Kaluza-Klein mode. In this case $N = 4$ and some allowed $n$ are shown. For the visualization, we choose by the opposite sign of $h_{R}^{j,1}$.

Figure A.9: Wave-Functions zero mode $h_{R}^{j,0}$, first mode $h_{R}^{j,1}$ of top fermion with right-handed zero mode and localization parameter $c_{R} = -0.12$, and Wave-Function first mode of gauge boson $f^{j,1}$ where $j$ is a index of site and $n$ is a index of Kaluza-Klein mode. In this case $N = 15$ and some allowed $n$ are shown.
Wave-Function of Excited States
Appendix B

For the vector-like quark SM SU(2)-doublet, we pass the interactions between $T'$, $B'$ the SM third generations and the EW gauge bosons from the EW to the mass eigenstate,

\[ \frac{g}{\sqrt{2}} T'_L W^+ b'_L + \frac{g}{\sqrt{2}} T'_L W^- t'_L \]
\[ + \frac{g}{c_w} T'_L Z \left( \frac{1}{2} - \frac{2}{3} s_w^2 \right) t'_L + \frac{g}{c_w} T'_L Z \left( -\frac{1}{2} + \frac{1}{3} s_w^2 \right) b'_L \]
\[ + \frac{2g_s w}{3} T'_L t'_L - \frac{g_s w}{3} T'_L A b'_L \]
\[ + \frac{g}{c_w} T'_R Z \left( \frac{2}{3} s_w^2 \right) t'_R + \frac{g}{c_w} T'_R Z \left( \frac{1}{3} s_w^2 \right) b'_R \]
\[ + \frac{2g_s w}{3} T'_R A t'_R - \frac{g_s w}{3} T'_R A b'_R \]
\[ + \frac{g}{\sqrt{2}} T'_L W^+ B'_L + \frac{g}{\sqrt{2}} T'_R W^- T'_L \]
\[ + \frac{g}{c_w} T'_L Z \left( \frac{1}{2} - \frac{2}{3} s_w^2 \right) T'_L + \frac{g}{c_w} T'_L Z \left( -\frac{1}{2} + \frac{1}{3} s_w^2 \right) B'_L \]
\[ + \frac{2g_s w}{3} T'_L t'_L - \frac{g_s w}{3} T'_L A B'_L \]
\[ + \frac{g}{\sqrt{2}} T'_R W^+ B'_R + \frac{g}{\sqrt{2}} T'_R W^- T'_R \]
\[ + \frac{g}{c_w} T'_R Z \left( \frac{1}{2} - \frac{2}{3} s_w^2 \right) T'_R + \frac{g}{c_w} T'_R Z \left( -\frac{1}{2} + \frac{1}{3} s_w^2 \right) B'_R \]
\[ + \frac{2g_s w}{3} T'_R t'_L - \frac{g_s w}{3} T'_R A B'_R, \] (B.1)
and then with the rotations defined by (3.166) into (B.1) we find that

\[
\begin{align*}
&\frac{g}{\sqrt{2}} \left( c'^{u}_{L} c'^{d}_{L} \bar{t} L W^{+} b_{L} + c'^{u}_{L} s'^{d}_{L} \bar{t} L W^{+} B_{L} + s'^{u}_{L} c'^{d}_{L} \bar{T} L W^{+} b_{L} + s'^{u}_{L} s'^{d}_{L} \bar{T} L W^{+} B_{L} + \text{h.c.} \right) \\
