1. Introduction

Polymer nanocomposites in recent years have become one of the most extensively studied materials all over the world due to their unusual properties of the synthesis of conducting polymers like polyaniline (PANI), poly-pyrrole (PPy) and polythiopene (PTh) due to their high electrical conductivity, interesting electrochemical properties, and easy processability [1-3]. These electrical and electro-chemical properties of such conducting polymers show much assurance for commercial applications in battery materials, electrochromic devices, sensor technology and nonlinear optics (NLO) [4]. Recent years several applications for the control of band gap is essential for light emitting diodes (LED) transparency in the visible region combined with high electrical conductivity etc., [5]. However, among various aromatic compound based conducting polymers, polyaniline is one of the most attractive conducting polymers due to its special transport properties, facile synthesis, tunable conductivity and good environmental stability [6]. Hence nanocrystalline materials are considerable interested due to their unique dielectric, magnetic and optical properties. We have selected zinc oxide nanoparticles due to their importance in wide range of applications in lithium batteries, high-density information storage devices, radar absorbing materials, magnetic fluids [7]. The semiconductor ZnO is a conventionally having wide band-gap. Its unique properties make it appropriate for various biomedical applications, such as anticancer, antibacterial, and antifungal uses [8-10]. The semiconductor properties of ZnO affect their ability to generate reactive oxygen species. The electrons in semiconductors contain energies within certain bands and the band gap, crystalline ZnO measures 3.3 eV for a void region extending from top of the filled valence band to the bottom of vacant conduction band. UV light contain sufficient energy to promote electron to the conduction band, leaving behind holes (h+). The electron and hole migrate to the surface of the nanoparticles and react with oxygen and hydroxyl ions, respectively. This leads to the formation of superoxide and hydroxyl radicals [11]. In this work we report optical absorbance, band gap, of pure polyaniline and polyaniline doped with zinc oxide (ZnO) nanoparticles.

2. Experimental Methods

2.1 Materials

Analytical reagent grade (AR) monomer pyrrole, oxidising agent ammonium persulphate (APS), zinc nitrate hexa hydrate, acetone and HQ, Whatman filter papers, double distilled water were used for the synthesis of polyaniline and Aloe vera plant used for green synthesis of ZnO nanoparticles.

2.2 Green Synthesis of ZnO Nanoparticles

The zinc oxide nanoparticles were synthesized by ‘self-propagating low temperature combustion method’ as shown in Fig. 1, employing zinc nitrate hexahydrate (Zn(NO3)2.6H2O) as a precursor and Aloe vera gel as a fuel.
A 10 mL of Aloe vera leaf extracted gel solution was prepared and then 2.1 mL of zinc nitrate was added with the extract and kept on a magnetic stirrer for 10 min constant stirring to get homogeneous solution. The uniform mixture of both oxidizer as well as the fuel was introduced into the pre-heated muffle furnace kept at 450 °C. The mixture boils with froth finally yielded a white powder of ZnO nanoparticles.

2.3 Synthesis of Polyaniline and PANI/ZnO Nanocomposites

The monomer aniline and oxidising agent ammonium persulphate (APS) used as catalyst were of analytical grade and procured from SD Fine Chemicals, India. The pyrrole monomer was used as received for the synthesis of polyaniline without further purification. The polymeric synthesis of polyaniline without further purification. The polymeric chemicals, India. The pyrrole monomer (APS) used as catalyst were of analytical grade and procured from SD Fine Chemicals, India. The pyrrole monomer was used as received for the synthesis of polyaniline without further purification. The polymeric

2.1 UV-Vis Spectrophotometer

The optical properties of the polyaniline and nanocomposites were studied using a double-beam monochromatic UV-Vis spectrophotometer. The optical absorption data of the polymer samples were recorded in the range of 200 nm to 800 nm at room temperature by using T90+ UV-visible spectrophotometer. UV-vis absorption spectra of polyaniline and PANI/ZnO nanocomposites are shown in Fig. 2. The spectrum of synthesized material exhibits absorption around the 335–470 nm which is the distinctive peak of polyaniline. The two different absorption peaks, at 335 nm and 470 nm were due to wide chain length distribution of polymer [12]. polyaniline exhibits two bands at 335 nm corresponding to π–π* intramolecular transition and the other band at 470 nm which is also corresponds to polaron band transitions, whereas the small peak at 385 nm was observed for doped polyaniline with ZnO nanoparticles which is attributed to transitions of the valence to polaron and bipolaron states which is the characteristic peak of ZnO nanoparticles [13,14]. The peak shift in wavelengths are observed after doping. The wavelength is shifted from 335 nm to 338 nm for nanocomposites of 10%, and 50% for 50% the wavelength is shifted from 335 nm to 340 nm.

The optical band gap can be measured from its UV-visible absorption spectra. The absorption coefficient (α) was calculated using the following Eq. (1) [15].

\[ \alpha(\nu) = \frac{A}{\nu} \]  

where \( A \) is the optical absorbance and \( \nu \) is the frequency. The sample is taken as solution, hence thickness is equal to cuvette length (sample cell) size as 1 cm. The value and nature of the optical band gap depends on absorption coefficient. The optical band gap can be calculated using the following Eq. (2) [16].

\[ (\alpha\nu)^2 = B(\nu - E_g) \]

where \( \alpha \) is absorption coefficient, \( h \) is Planck’s constant, \( \nu \) is the frequency, \( B \) is a constant which depends on the transition probability, \( E_g \) is the optical band gap and \( n \) is an index which indicates the optical absorption process. Theoretically, it is equal to 2 for direct allowed transition, 1/2 for indirect allowed transition, 2/3 for direct forbidden transition and 1/3 for indirect forbidden transition [17]. In the present case, the band gap has been calculated for pure polyaniline and PANI/ZnO nanocomposite at 50%. For the determination of optical band gap, \( (\alpha\nu)^2 \) was plotted as a function of photon energy \( h\nu \). The value of direct band gap \( E_g \) was calculated from the intersection of the extrapolated line with the photon energy axis \( (\alpha\nu)^2=0 \) using the linear portion of absorption edge of the UV-Vis absorption spectra. By the calculation, the optical band gap for pure polyaniline and PANI/ZnO nanocomposites are obtained as 3.78 eV and 3.68 eV respectively.

3.2 X-Ray Diffraction Analysis

To study the nature of crystallinity or amorphous, powder XRD characterisation have been done for pure PANI, pure PVDF and polymer blended PANI with PVDF/KDP composites. The X-ray diffraction patterns of the samples are obtained using a Philips X-ray diffractometer with CuKα radiation (\( \lambda = 1.54060 \text{ Å} \)). The diffractograms were recorded in terms of 2θ in the range 10 to 90 degrees with a scanning rate of 4 degrees per minute. Figs. 3–5 show the XRD pattern of synthesized pure PANI, ZnO NPs and polymer PANI/ZnO composites. PANI X-ray diffraction pattern at Fig. 3 shows a broad peak occurred at 2θ = 25.58° which is the characteristic peak says the amorphous nature of PANI [18].

3.3 XRD Analysis of ZnO Nanoparticles

It is observed from Fig. 4 that the powder XRD patterns of ZnO NPs characteristic diffraction peaks of ZnO including the planes (100) (002), (101), (102), (110), (103), (200), and (112), (201), (004), (202) were observed at an angle 31°, 34°, 36°, 47°, 56°, 63°, 66°, 67°, 69°, 72°, and 77° for the synthesised ZnO nanoparticle sample. All the diffraction peaks are well assigned to the hexagonal wurtzite phase of ZnO [JCPDS card No. 36-1451] [19]. The presence of the high intensity peaks inferred that the prepared sample were highly crystalline in nature. The average particle size of the ZnO nanoparticles was found by using Debye-Scherer formula is 20-50 nm.
The dielectric constant decreases. The dielectric properties studies on PANI/ZnO composites indicates that the semi-crystalline nature of prepared sample PANI/ZnO composites are determined [20, 21].

3.3 Dielectric Properties

The dielectric properties have been studied for all the PANI and PANI/ZnO composites as a function of frequency at room temperature.

3.3.1 Dielectric Constant

The dielectric constant with frequency for PANI and PANI/ZnO composites of different weight percentages are shown in the Fig. 3. Using the values of capacitance the dielectric constant were determined for PANI and PANI/ZnO at 10, 30, and 50 wt%, using the expression Eq (3) [22]

\[ \varepsilon' = \frac{Cd}{\varepsilon_0 A} \] (3)

where \( d \) is the thickness of the sample, \( A \) is the effective cross-sectional area of the sample, \( C \) is the capacitance of the sample. The dielectric constant of PANI and PANI/ZnO composites decreased as frequency increased up to 180.9 Hz, which is shown in Fig. 3. The dielectric constant remains almost constant after frequency of 180.9 Hz and it shows independent of frequency because of electrical relaxation process. It is observed that for PANI and PANI/ZnO composites as weight percentage of ZnO NPs increases the dielectric constant decreases. The dielectric constant decreases due to the shorter time available for the dipoles to align [23].

3.3.2 Dielectric Loss

The dielectric loss with frequency for PANI and PANI/ZnO composites of different weight percentages are shown in the Fig. 4. The dielectric loss is obtained with the help of experimental data of dissipation factor and the values of dielectric constant using the relation given by,

\[ \varepsilon'' = \varepsilon'\tan\delta \] (4)

Fig. 7 shows dielectric loss decreased gradually as frequency increased higher values for all the composites of PANI/ZnO. But for PANI it decreases as the frequency increases for higher values. The dielectric loss \( \varepsilon'' \) decreases due to the migration of ions in the material [24].

3.3.3 AC Conductivity

The AC conductivity as a function of frequency for PANI and PANI/ZnO composites of different weight percentages at room temperature are shown in the Fig. 4.

Fig. 5 The X-ray diffraction pattern for PANI and PANI/ZnO composites
