Abstract

The meal complexes of Co(II), Ni(II), Cu(II), Cd(II) and Zn(II) derived from hydroxyl benzophenone and o-phenylenediamine have been synthe"nised and characterized by elemental analysis, 1H NMR, FT-IR, UV-visible, Mass spectroscopy, molar conductometry, magnetic susceptibility and thermal analysis study. The FT-IR spectral study reveals that the ligand behaves as a dibasic tetradentate ligand with N2O2 donor atoms sequence towards central metal ion. The physico-chemical study reveals octahedral geometry for the complexes. The results show the formation of 2:1(ligand: metal chloride) complexes with amine and screened for anti-inflammatory, antimicrobial, DNA binding properties.

Introduction:

During the past two decades, considerable attention has been paid to the chemistry of metal complexes containing nitrogen and other donor1. The tetrarradate Sch"iff base complexes are well known to form stable complexes, where coordination takes place through the N2O2 donor set2-4. N, O-bidentate and N2O2-tetradentate ligands (soft and hard donor) possess many, advantages such as facile approach, relative tolerance, readily adjusted ancillary ligands, and tunable steric and electronic coordination environments on the metal center5. This may be attributed to their potential application in many fields such as oxidation catalysis6 and electrochemistry7. Transition metals are involved in many biological processes which are essential to life process. The metals can coordinate with O- or N-terminals from proteins in a variety of models and play a crucial role in the conformation and function of biological macromolecules8, 9. This paper reports the synthesis, characterization, thermal and biological studies of metal(II) complexes derived from the reaction of hydroxyl benzophenone and o-phenylenediamine in alcohol.

Experimental section:

Materials and Methods:

All the chemicals used in the preparation of Schiff base and its metal complexes were of AR grade. A Perkin-Elmer CHN analyzer (model 2400) was used for C, H and N analyses. The room temperature molar conductance was determined using a Century digital conductivity meter (model cc 601) with a dip type cell and a smooth platinum electrode. The electronic absorption spectra of the complexes were recorded as dilute solutions on a Shimadzu 160A/240A UV-visible spectrophotometer. The 1H NMR spectra were recorded using Bruker DRX 400 spectrometer at 400 MHz with TMS as the internal standard. Mass spectra were obtained with a VG70-70H
spectrophotometer. The infrared spectra of the solid samples were recorded in the range 4000-500 cm\(^{-1}\) on a Perkin-Elmer 597/1650 spectrophotometer using KBr pellets. The magnetic moments were measured out using gouy balance. Purity of the compound was checked by TLC\(^{10}\).

General procedure for the preparation of complexes (vM₁-M₈):
A solution of ligand (ivab) and cobalt(II) chloride hexa hydrate in 1:1 molar ratio in ethanol was refluxed for 6 hours. The resulting solution was reduced to half of its volume and kept aside. On standing, the obtained solid product was filtered off and washed with water and ethanol. The product (vM₁-M₈) was recrystallized from a mixture of chloroform and ethanol (3:1) and stored over anhydrous calcium chloride.

vM₁: Yield 60%; M.p. >250°C; IR (Nujol): (M-O) 462, (M-N) 527, (C=N) 1645 cm⁻¹ (H₂O) 3562 cm⁻¹. MS: m/z 628; Anal.Calcd.for C₃₂H₂₉Cl₁₉N₂O₇Co(H₂O)₂ (628): C, 61.14; H, 3.18; N, 4.45. Found: C, 61.23; H, 3.10; N, 4.73%. Molar conductance: 18.9, Magnetic moment: 4.50 B M.

vM₂: Yield 65%; M.p. >250°C; IR (Nujol): (M-O) 470, (M-N) 515, (C=N) 1652 cm⁻¹ (H₂O) 3570 cm⁻¹. MS: m/z 628; Anal.Calcd.for C₃₂H₂₉Cl₁₉N₂O₇Ni(H₂O)₂ (628): C, 61.12; H, 3.17; N, 4.28 Found: C, 61.02; H, 3.07; N, 4.35%. Molar conductance: 16.2, Magnetic moment: 3.11 B M.

Biology:-
Materials and Methods:-
Hemolysing buffer [0.85% NH₄Cl, 10mM Tris pH 7.4]. Calf thymus DNA was purchased from Genie Company. Viperarusselli venom was obtained from IRULA snake catchers (Madras). Micro organisms were procured from university of Mysore, Department of Microbiology. All other chemicals are purchased from Sisco Research laboratory, Mumbai, India. All reagents were of analytical grade.

Antimicrobial Evaluation:-
The newly synthesized Schiff- base derivatives (iva,b, vM₁-M₈) were evaluated in vitro for antibacterial activity against Staphylococcus aureus and Streptococcus epidermidis as examples of Gram-positive bacteria and Listeria monocytogenes and Escherichia coli as examples of Gram-negative bacteria. They were also evaluated in vitro for their antifungal activity against Candida albicans. Inhibition zone diameter (IZD) in cm was used as criterion for the antimicrobial activity using agar diffusion well method. Gentamycin and Flucanazole were used as reference drugs for antibacterial and antifungal activity respectively. Microbes were grown in Nutrient Broth (NB, Merck) medium at 37°C for 24h. The bacterial number in the final inoculums was adjusted to 10⁶ CFU/ml. A bacterial lawn was prepared by pouring 0.1 ml of bacterial suspension onto each plate of Nutrient Agar medium (NA, Merck), spread by a sterile cotton swab, and allowed to remain in contact for 1 min. Schiff base derivatives of different concentrations (20µg,40µg,80µg,100µg) were prepared in order to impregnate the paper discs. The sterile filter
paper discs containing Schiff-base derivatives (6-mm diameter) were then placed on the bacterial lawn. The Petri dishes were subsequently incubated at 37°C for 24 h and the inhibition zone around each disc was measured in cm.

**Anti inflammatory activity:-**

**Indirect Haemolytic assay of PLα2:-**

Protein concentration in the venom was calculated, using bovine serum albumin fraction V (0-75µg). A semi quantitative indirect haemolytic assay was employed. Briefly, packed human erythrocytes, egg yolk and phosphate buffer saline was mixed (1:1:8 V/V). 1ml of this suspension was incubated with 60 µg enzyme for 10 min at 37°C. The reaction was stopped by adding 9ml of cold phosphate buffer saline and centrifuged at 4°C for 10 min at 800Xg. The amount of haemoglobin released in the supernatant was measured at 540nm. The assay was also carried out in the presence of various concentrations 200-1000ng/ml. Enzyme and substrate without the inhibitor served as control.

**DNA Binding and chelating assay using Calf thymus DNA:-**

For the gel electrophoresis study, calf thymus DNA (20μg) was treated with the 10 µg of Schiff base derivatives and incubated for 30 minutes in 40mM Tris-buffer (pH 8.3). The samples were electrophoresed for 3 hours at 50 V on a 1% agarose gel in Tris–acetic acid–EDTA buffer. The gel was stained with 0.5 µg of ethidium bromide. Photographed under UV light.

**Cell viability assay:-**

Tryphan blue exclusion test is based on the principle that living cell membrane has the ability to prevent the entry of the dye, hence they remain unstained and can be easily distinguished from the dead cell which take up the dye. The percentage of viable cells was determined by diluting the isolated lymphocytes with 0.4% tryphan blue, mixed and loaded into haemocytometer. The viable cells were counted under microscope and % of viability was calculated.

**Isolation of Human Peripheral Lymphocytes:-**

10ml of blood and 2ml of ACD were mixed, it is incubated with 4 volumes of haemolysing buffer at 4°C for 30 minutes centrifuged at 1500 rpm for 12min at 4°C, pellet was subjected to 10ml lysing buffer, centrifuged at 1500 rpm for 12 min, pellet was washed with HBSS solution, suspended in 2ml of same solution.

**Cell Viability by dye exclusion method:-**

Lymphocytes (10x10^6) suspended in 1ml of HBSS were treated with Schiff base derivatives(5µl -500ng) dissolved in DMF and incubated for 60 minutes in a shaking water bath at 37°C. At the end of incubation, aliquot of cells was taken for viability assay by tryphan blue exclusion method. Stained and stainless cells were counted. % of viable cell calculated by using the following formula

\[
\% \text{ of viable cells} = \frac{\text{number of living cells}}{\text{Total number of cells}} \times 100
\]

**Result and discussion:-**

**Chemistry:-**

Benzoylation of phenols, Fries rearrangement used to convert a phenyl ester to an ortho- and para-hydroxy aryl ketone.

Based on these information ligands were achieved by condensation reaction of substituted hydroxybenzophenone (ii) with o-phenylenediamine in presence of methanol by adopting the above method. Benzoyl phenol based cobalt(II), nickel(II), cadmium(II) and copper(II) complexes were synthesised using respective salts and organic ligands. All the complexes are colored, stable at room temperature, soluble in DMSO and melt with decomposition above 250°C. Unfortunately, our efforts to obtain single crystals of complexes were not successful. The ligands and their complexes were characterized on the basis of elemental analysis, ^1H NMR, IR, magnetic susceptibility measurement, electronic spectra data, colours, melting point, partial elemental analyses and molar conductivities. The elemental analysis of the compounds is in good agreement with their proposed formulae and the molar conductance of all the complexes in DMSO shows that they are non-electrolytes. Thin layer chromatographic analysis was monitored for the progress of the reactions. The yield, elemental analysis and molar conductance data of metal complexes are presented in Table 1.1 and 1.2.
FT IR Spectra:-
The IR spectra of the complexes were compared with those of the free ligands in order to determine the coordination sites that may be involved in chelation. There were some guide peaks in the spectra of the ligands, which were helpful in achieving this goal. The IR spectra of the ligands (iva,b) show a very strong band at 3505 cm$^{-1}$ and 3502 cm$^{-1}$ was assigned to in-plane bending (O-H) vibration. The absence of (O-H) stretching and ν(O-H) vibration in the spectra of the complexes indicated deprotonation of the –OH groups$^{14}$. The strong band observed in the region 1665 and 1668 cm$^{-1}$ in the ligands (iva,b) assigned to C=N stretching. The complexes show a strong band at 1634-1653 cm$^{-1}$ (νM–N) representing the C=N stretching moiety. This band is shifted to a lower frequency by ~ 15-26 cm$^{-1}$, as compared to the corresponding ligands indicating that the azomethine nitrogen of the C=N group has participated in coordination$^{15}$. This can be ascribed to the withdrawn of electron density from the nitrogen atom owing to coordination. The phenolic ν(O-H) band is shifted from 3505 (iva) and 3502 (ivb) to 1267–1278 (νM1–M0) as a consequence of the delocalization of double bond in chelate rings that has increased the bond order of the phenolic C-O. The phenolic oxygen, after the loss of O-H proton gets coordinated to the metal. This is supported by shift in the stretching frequency of ν(C-O) to lower wave number from its position in the free ligand$^{16}$. In addition all the complexes showed additional weak to medium intensity bands in the region new 460-500 and 520-590 cm$^{-1}$ (νM1–M0) which were absent in the spectra of ligand, these can be attributed to ν(M-O) and ν(M-N) respectively$^{17-19}$. The IR spectra showed a strong band in 3550-3575 cm$^{-1}$ region (νM1–iνM0), suggesting the presence of coordinated water.

$^1$H NMR Spectra:-
The $^1$H NMR spectra of ligands and their complexes re-recorded in DMSO revealed the formation of the complexes from their ligands. The proton NMR spectrum of the Schiff base ligand iva shows singlet peak at 10.7 ppm which corresponds to the two phenolic-OH groups which is absent in the spectrum of Cd(II) complex. This indicates that the deprotonated phenolic-O atom is involved in chelation. Both the ligand and Cd(II) complex show a group of multiplet (6.9–8.1 and 6.6–7.4 ppm). The presence of a peak in the region 4.7 ppm reveals the presence of coordinated water molecules in the complex.

Magnetic Measurements and Electronic Spectra:-
The magnetic moment of the complexes were measured at room temperature. The electronic spectra of the Schiff base ligands and their Co(II), Ni(II), Cd(II) and Cu(II), complexes have been measured in DMF solution between 200-1800 nm at room temperature. The electronic absorption spectra are often very helpful for structural investigation. The electronic spectral measurements were used for assigning the geometry of metal ions in the complexes based on the positions and number of d-d transition peaks. Magnetic properties arise from the spin and orbital angular momentum of the electrons contained in a compound.

In the spectra of the Schiff base ligands the absorption band observed at 275-293 nm were assigned to a π→π* transition and the band at 355-398 nm were assigned due to n→π* transition associated with the azomethine chromophore (–C=N). The new bands in complexes near 457-515 nm can be assigned to L→M charge transfer band.

The magnetic moment of the complexes were measured at room temperature. The magnetic moment of the cobalt (II) lay in the range 4.50 and 4.55 BM (ivM1 and ivM4) which corresponds to 3 unpaired electrons. The solution spectra of the cobalt (II) complexes exhibited absorption in the region 290, 320, 440 (ivM1) and 270, 340, 450nm (ivM4). The spectra resemble that reported for octahedral complex$^{20}$. Thus the various bands can be assigned to: $^4$T$_{1g}$→$^4$T$_{2g}$, $^4$T$_{1g}$→$^4$A$_{2g}$, $^4$T$_{1g}$→$^4$T$_{1g}$.
The magnetic moment of the nickel (II) lay in the range 3.11 and 3.02 BM (vM₂ and vM₆) which corresponds to 2 unpaired electrons. The solution spectra of the nickel (II) complexes exhibited absorption in the region 330, 380, 420, 470 (ivM₂) and 350, 375, 480, 490 nm (ivM₆), The spectra resemble that reported for octahedral complex. Thus the various bands can be assigned to: 4T₁g → 4T₂g, 4T₁g → 4A₂g, 4T₁g → 4T₁g and L→M charge transfer respectively.

The observed magnetic moment of the Cu(II) complexes are 1.92 and 1.90 BM (vM₄ and vM₈) which confirms the octahedral structure of this complex. For octahedral Cu(II) complexes, the expected transition is assigned to 2Eg → 2T₂g transition. Due to Jahn–Teller distortions, Cu(II) complexes give a broad absorption at 615 and 695 nm (vM₄ and vM₈).

Cd(II) ion with d₁₀ electronic configuration permits a wide range of symmetries and coordination numbers. Since d₁₀ configuration affords no crystal field stabilization, the stereochemistry of a particular compound depends on the size and polarizing power of the M(II) cation and the steric requirement of the ligands and have no d–d transition and is diamagnetic.

Analytical, conductance and magnetic moment data of compound.

Biology:

Figure 1: Effect of Schiff-base on the activity of PLA2

vM_{1}, vM_{2} and vM_{3} have showed the maximum inhibition with IC50 value of 531 µg/ml, 539 µg/ml and 547 µg/ml respectively which is followed by compounds vM_{4}, iva, vM_{6}, vM_{7}, vM_{8} and ivb. Showed inhibition with IC50 value of 563 µg/ml, 578 µg/ml, 612 µg/ml, 638 µg/ml, 655 µg/ml, 671 µg/ml and 684 µg/ml respectively. All the compounds show almost complete inhibition at less than 1 µg/ml.
Table 4:- IC$_{50}$ Value of PLA2 inhibition by Schiff- base derivatives.

| Compounds | IC50 value (µg /ml) |
|-----------|---------------------|
| iva       | 578                 |
| vM$_1$    | 563                 |
| vM$_2$    | 547                 |

Antimicrobial activity:-
Compounds (iva, vM$_1$ to vM$_4$ and ivb, vM$_5$ to vM$_8$) were tested in vitro for their antimicrobial activity against two Gram-positive and two Gram-negative bacterial strains. Commercial antibiotics such as gentamycin and flucanazole were used as standard drugs. The results were compared with standard drugs and depicted in Table 5. Among the Schiff- base derivatives (vM$_1$ to vM$_4$ and vM$_5$ to vM$_8$) compound vM$_1$ and vM$_6$ were showing maximum antibacterial activity than the other Schiff-base derivatives. vM$_2$ is potent against both Gram+ve and Gram –ve bacteria, only vM$_1$ and vM$_2$ of showed antifungal activity with the MIC of 9.9µg and 18.63µg/ml respectively. vM$_4$ did not show any microbial activity.

Cell viability assay:-
The cell viability assay reveals that the compounds vM$_1$ to M$_3$ and vM$_5$ to M$_7$ are found to be cytoplasmic protective in nature as the percent viability is greater than the control. The compound M$_4$ and ivb appears to be cytotoxic as the percent viability was lesser than the control. iva was found to be neither cytotoxic nor cytoprotective as the percent viability is similar to that of control.
**Table no 6: Percentage of viable cells after treated with Schiff- base derivatives**

|          | Cell viability % |
|----------|------------------|
| Control  | 30.84            |
| M₁       | 38.88            |
| M₂       | 48.97            |
| M₃       | 34.69            |
| M₄       | 39.21            |
| iva      | 30.95            |
| M₅       | 20.58            |
| M₆       | 48.33            |
| M₇       | 45.76            |
| M₈       | 15.55            |
| ivb      | 8.43             |

**DNA chelating activity of Schiff- base derivatives:**

|          |          |          |          |          |          |          |          |
|----------|----------|----------|----------|----------|----------|----------|----------|
| C        | iva      | vM₁      | vM₂      | vM₃      | vM₄      | C        | ivb      | vM₅      | vM₆      | vM₇      | vM₈      |

**Figure 2:** Photographs showing the effects of Schiff-base derivatives on Calfthymus DNA

Gel electrophoresis picture is shown in figure 2. The photograph shows the bands with different band width and brightness compared to the control. The difference observed in the band width and intensity is the criterion for the evaluation of binding/cleavage ability of Schiff- base derivatives with calf thymus DNA. **Figure 2.** Shows the bands with different light intensity compared to the control probably because of degradation of DNA by the compounds. There is significant binding of DNA in all lanes of M₁ to M₄ of scheme1 as there is increase in intensity in the DNA bands as shown in figure 2. The compound iva and α of ivb not only bound to the DNA but also degraded the DNA as it can be confirmed by the less intensity of the DNA. The remaining compounds are not involved in the degradation of the DNA, the same thing is also confirmed by cell viability assay.

**Conclusion:**

The author has synthesized and characterized two new schiff-base ligands (iva, ivb) and eight metal complexes (vM₁-M₈). These complexes have been characterized by utilizing the various physico-chemical methods. The molecular formulae of the complexes were calculated from the elemental analyses data and are in good agreement with theoretical values. The observed molar conductance of all the complexes in DMSO, magnetic susceptibility and spectral data confirm octahedral environment around the M(II) ions with N, O as donor atoms and shows that they are non-electrolytes. The presence of coordinated water molecules in all the complexes has been further confirmed from IR. The mass spectrum of the complex confirms the proposed structure. Based on these evidences the following structures have been proposed for the complexes. A series of Schiff-base derivatives, iva, M₁-M₄ and M₅-M₈ of were screened for their DNA binding and chelating, anti-inflammatory and antimicrobial activity. Of the ten compounds tested M₁ and M₂ found to be potent antimicrobial compound with broad specificity, M₆ and M₇ showed only antibacterial activity. The compound iva and ivb were found to have potent DNA binding and chelating ability the remaining compounds were found to be cyto protective in nature but all the compounds proven to be potent.
anti-inflammatory compounds as they were showing more inhibition of PLA₂ which is a pro enzyme to induce inflammation.
