Abstract

Background: Hemoptysis is a challenging symptom which can be associated with potentially life-threatening medical conditions. Follow-up is key in these patients to early detect new or misdiagnosed pathologic findings. Few prospective studies evaluated long-term prognostic outcomes. Furthermore, the role played by antiplatelet and anticoagulant drugs on mortality and recurrence rates is unclear.

The aim of the study was to assess the mortality after 18 months of follow-up; furthermore, it was evaluated the incidence of recurrences and the factors associated with both recurrence and death (including the role played by anticoagulant and antiplatelet drugs).

Methods: Observational, prospective, multicentre, Italian study.

Results: 451/606 (74.4%) recruited patients with hemoptysis completed the 18 months follow-up. 22/604 (3.6%) diagnoses changed from baseline to the end of the follow-up. 83/604 (13.7%) patients died. In 52/83 (62.7%) patients, death was the outcome of the disease which caused hemoptysis at baseline. Only the diagnosis of lung neoplasm was associated with death (OR (95%CI): 38.2 (4.2-347.5); p-value: 0.0001).

166 recurrences were recorded in 103/604 (17%) patients. The diagnosis of bronchiectasis was significantly associated with the occurrence of a recurrence (OR (95% CI): 2.6 (1.5-4.3)); p-value <0.0001).

Anticoagulant, antiaggregant, and anticoagulant plus antiaggregant drugs were not associated with an increased risk of death and recurrence.

Conclusions: Our study showed a low mortality rate in patients with hemoptysis followed-up for 18 months. Pulmonary malignancy is the main etiology and the main predictor of death, whereas bronchiectasis is the most frequent diagnosis associated with recurrence. Antiplatelet and/or anticoagulant therapy do not change the risk of death or recurrence. Follow-up is recommended in patients initially diagnosed with lower airways infections and idiopathic bleedings.

Clinical trial registration: NCT02045394.

Background

Hemoptysis is a challenging symptom which can be associated with potentially life-threatening medical conditions\(^1,2\). Recent studies showed that lung cancer, bronchiectasis, and lower respiratory tract infections are the most frequent etiologies\(^2-8\). However, despite an accurate initial work-up, a subgroup of patients with hemoptysis does not have an etiological diagnosis (\(i.e.,\) idiopathic or cryptogenic hemoptysis)\(^2-9\); furthermore, diagnostic changes from the baseline assessment to recurrences were recently described\(^2,9\). In particular, lung cancer was found in patients with idiopathic hemoptysis or lower
respiratory infections and a diagnosis of bronchiectasis was performed in a non-negligible proportion of patients initially diagnosed with cryptogenic bleeding\textsuperscript{2,10}.

In this context, follow-up is key to detect new or misdiagnosed pathologic findings (e.g., lung malignancy)\textsuperscript{2,6,8}.

Several factors might influence the long-term prognostic outcomes of patients with hemoptysis. Few prospective studies evaluated their survival rate, the mortality-related risk factors, as well as the incidence of recurrence and its associated variables\textsuperscript{7,8}. Furthermore, the role played by antiplatelet and anticoagulant drugs is still unclear.

The primary aim of this study was to assess the mortality after 18 months of follow-up; furthermore, the incidence of recurrences and the clinical factors associated with recurrence and mortality were evaluated. The role of anticoagulant and antiplatelet drugs on these outcomes was also studied.

**Materials And Methods**

**Study design**

This is a secondary analysis of an observational, prospective, multicentre, Italian study aimed at evaluating the epidemiology of hemoptysis in Italy and the diagnostic yield of the most frequently prescribed diagnostic techniques\textsuperscript{5}. It was approved by the ethical committees of five Italian participating hospitals and registered at ClinicalTrials.gov (identifier: NCT02045394). Written informed consent was signed by all recruited patients\textsuperscript{5}, who were followed-up for 18 months.

One month after the recruitment and the first initial assessment, a hospital clinical re-evaluation was scheduled. After three, six, nine, twelve, and eighteen months a phone call was planned for every patient. At each follow-up visit information on occurrence, timing, and severity of recurrences was collected.

In case of recurrence a new clinical assessment was performed; data on clinical, radiological, endoscopic examinations, as well as on symptom management were recorded.

**Patients and interventions**

From July 2013 to September 2015, adult (i.e., $\geq 18$ years old) patients with haemoptysis requiring an etiological diagnosis were considered eligible for recruitment\textsuperscript{5} and consecutively enrolled. Exclusion criteria were the following: 1) etiology of haemoptysis already known; 2) refusal to sign the informed consent.

The follow-up period lasted from December 2015 to February 2018.

Severity of haemoptysis was graded by the first attending physician. Patients were divided into three groups based on the total amount of blood expectorated in 24 hours (h)\textsuperscript{5,7}: mild (i.e., drops of blood to 20
millilitres (ml)/24 h), moderate (i.e., 20–500 ml/24 h), severe (i.e., > 500 ml/24 h).

**Outcome measures**

The primary outcome was the survival rate of patients with hemoptysis. Furthermore, it was calculated the incidence of recurrence and the main factors associated with recurrence and the mortality. The effectiveness of antiplatelet and anticoagulant drugs on these outcomes was specifically investigated.

Changes in the diagnosis of hemoptysis from baseline to the end of follow-up were recorded.

**Statistical analysis**

Qualitative and quantitative variables were collected with an ad hoc electronic form. Qualitative variables were described with absolute and relative (percentage) frequencies, whereas quantitative variables were summarized with medians (interquartile ranges, IQR) for their non-parametric distribution. Univariate and multivariate logistic regression analysis was performed to assess the relationship between clinical, demographic, and epidemiological variables and the outcomes death and recurrence. A two-tailed p-value less than 0.05 was considered statistically significant. All the statistical computations were performed with the statistical software STATA version 16 (StatsCorp, Texas, USA).

**Results**

451 out of 606 (74.4%) patients who were recruited completed the 18 months’ follow-up.

The initial etiological diagnoses were previously described. In addition to specific etiological therapy, bronchial artery embolization was performed in 13/606 (2.1%) patients, bronchoscopy was performed with a therapeutic aim (e.g., administration of topical vasoconstriction, Fogarty balloon, endobronchial argon plasma coagulation and laser therapy) in 99/604 (16.4%) patients. Oral and intravenous tranexamic acid were prescribed in 119/606 (19.6%) patients. 70/606 (11.5%) patients were lost to follow-up, whereas 83/606 (13.7%) died during the study-period. 15/83 (18.1%) patients died within one month after the enrollment, 21/83 (25.3%) between the first and the third month of follow-up, 14/83 (16.9%) between the third and the sixth month, 26/83 (31.3%) between the sixth and the twelfth month, and 7/83 (8.4%) between the twelfth and the eighteenth month.

In 52/83 (62.7%) patients, death was the outcome of the disease which caused hemoptysis at baseline: 42 died for lung cancer (eight during a recurrence), seven patients for metastatic pulmonary malignancy, two patients for pneumonia, and one for a bronchiectasis exacerbation. One patient, initially diagnosed with idiopathic hemoptysis, died during a recurrence without an identifiable cause of bleeding.

In the univariate analysis, age > 70 years (odds ratio, OR, (95%CI): 9.5 (1.3–70.5); p-value: 0.03), being male (OR (95%CI): 2.3 (1.3–4.1); p-value: 0.005), moderate hemoptysis (OR (95%CI): 1.9 (1.2-3.0), p-value: 0.01), smoking history (≥10 pack/years: OR (95%CI): 3.5 (1.8–6.7); p-value: <0.0001; ≥ 30...
pack/years: 1.9 (1.1–3.4)); p-values: 0.02), and pulmonary malignancy (OR (95%CI): 15.6 (9.2–26.5); p-value: <0.0001) were associated with an increased risk of mortality. In the multivariate analysis only the diagnosis of lung neoplasm resulted significantly associated with the above-mentioned outcome (OR (95%CI): 38.2 (4.2-347.5); p-value: 0.0001) (Table 1).
| Demographic and clinical variables predictive of mortality in patients with hemoptysis |

22/606 (3.6%) diagnoses changed from baseline to the end of the follow-up (Table 2). In particular, pulmonary malignancy was described in four cases initially diagnosed with idiopathic bleedings, in two patients with an exacerbation of chronic obstructive pulmonary disease (COPD) (both with a smoking history > 20 pack/years), and in four patients with pneumonia/lung abscess (two of them active smokers). In 7/22 (32%) patients the new diagnosis was performed during a recurrence: lung cancer was described in two patients with an initial diagnosis of pneumonia/lung abscess and in one with an idiopathic bleeding. In two patients an upper airways lesion was found after an initial diagnosis of acute bronchitis and idiopathic bleedings. An upper digestive hemorrhage and a pulmonary embolism were diagnosed in two patients initially diagnosed with cryptogenic hemoptysis and pneumonia, respectively.

Table 2
Variation in the diagnosis from the initial assessment after 18 months follow-up

| Initial diagnosis                  | Diagnosis at the end of the follow-up | Patients number |
|-----------------------------------|---------------------------------------|-----------------|
| Pneumonia/lung abscess            | Lung cancer                           | 4               |
| Pneumonia/lung abscess            | Pulmonary embolism (with infarction)  | 2               |
| Pneumonia/lung abscess            | Bronchiectasis                        | 1               |
| Cryptogenic hemoptysis            | Lung cancer                           | 4               |
| Cryptogenic hemoptysis            | Upper airways bleeding disease        | 1               |
| Cryptogenic hemoptysis            | ILD                                   | 1               |
| Cryptogenic hemoptysis            | Hematemesis                           | 1               |
| COPD exacerbation                 | Bronchiectasis                        | 2               |
| COPD exacerbation                 | Pulmonary malignancy                  | 1               |
| COPD exacerbation                 | Lung cancer                           | 1               |
| Acute bronchitis                  | Bronchiectasis                        | 1               |
| Acute bronchitis                  | COPD exacerbation                     | 1               |
| Acute bronchitis                  | Upper airways bleeding disease        | 1               |
| Acute bronchitis                  | ILD                                   | 1               |
| COPD: chronic obstructive pulmonary disease; ILD: interstitial lung disease

166 recurrences were recorded in 103/606 (17%) patients (Table 3). The median (IQR) number of events was 1 (1–2). Recurrences were recorded in 28/103 (27.2%) patients with bronchiectasis (45 bleeding events), in 24/103 (23.3%) with pulmonary malignancy (22/103 (21.4%) with lung cancer (26 events) and 2/103 (1.9%) with pulmonary metastasis (4 events), in 13/103 (12.6%) with pneumonia/lung abscess (21 events). Bronchiectasis and pneumonia/lung abscess related recurrences were mostly mild (20 (71.4%)
and 13 (100%) patients, respectively), whereas in case of lung cancer mild to moderate bleedings were found in 10 (45.5%) patients. 2 (7.1%) severe recurrences were recorded in patients with both bronchiectasis and lung cancer.

|                  | Events | Patients | Mild   | Moderate | Severe |
|------------------|--------|----------|--------|----------|--------|
| Bronchiectasis, n (%) | 45     | 28 (27.2)| 20 (71.4)| 6 (21.4) | 2 (7.1) |
| Pulmonary malignancy, n (%) | 30     | 24 (23.3)| 11 (36.6)| 11 (36.6)| 2 (0.8) |
| Lung cancer, n (%)      | 26     | 22 (21.4)| 10 (45.5)| 10 (45.5)| 2 (9.1) |
| Pulmonary metastasis, n (%) | 4      | 2 (1.9)  | 1 (50.0)| 1 (50.0)| 0 (0.0) |
| Pneumonia/lung abscess, n (%) | 21     | 13 (12.6)| 13 (100)| 0 (0.0) | 0 (0.0) |
| COPD (exacerbation), n (%)      | 13     | 7 (6.8)  | 7 (100.0)| 0 (0.0) | 0 (0.0) |
| Acute bronchitis, n (%)      | 11     | 7 (6.8)  | 7 (100.0)| 0 (0.0) | 0 (0.0) |
| Cryptogenic hemoptysis, n (%) | 10     | 6 (5.8)  | 5 (83.3)| 1 (16.7)| 0 (0.0) |
| Upper airways bleeding disease, n (%) | 8      | 4 (3.9)  | 2 (50.0)| 2 (50.0)| 0 (0.0) |
| Post-tuberculosis sequelae, n (%) | 8      | 3 (2.9)  | 2 (66.7)| 1 (33.3)| 0 (0.0) |
| Other pulmonary/bronchial vascular lesion, n (%) | 5      | 2 (1.9)  | 1 (50.0)| 0 (0.0) | 1 (50.0) |
| Pulmonary embolism, n (%) | 5      | 2 (1.9)  | 1 (50.0)| 1 (50.0)| 0 (0.0) |
| Atypical mycobacteriosis, n (%) | 2      | 1 (1.0)  | 1 (100.0)| 0 (0.0)| 0 (0.0) |
| Active tuberculosis, n (%)    | 2      | 2 (1.9)  | 1 (50.0)| 1 (50.0)| 0 (0.0) |
| Iatrogenic or traumatic, n (%)     | 2      | 1 (1.0)  | 1 (100.0)| 0 (0.0)| 0 (0.0) |
| Tracheal granuloma, n (%)      | 2      | 1 (1.0)  | 1 (100.0)| 0 (0.0)| 0 (0.0) |
| Hematemesis, n (%)     | 1      | 1 (1.0)  | 0 (0.0) | 1 (100.0)| 0 (0.0) |
| Interstitial lung disease, n (%) | 1      | 1 (1.0)  | 1 (100.0)| 0 (0.0)| 0 (0.0) |

The univariate analysis showed that bronchiectasis was significantly associated with the occurrence of a recurrence (OR (95% CI): 2.6 (1.5–4.3)); p-value < 0.0001) (Table 4).

Anticoagulant, antiaggregant, and anticoagulant plus antiaggregant drugs were not significantly associated with an increased risk of mortality and recurrence (Table 5).
### Table 5
Role played by antiplatelet and anticoagulant therapy, alone and combined, on recurrence and mortality in patients with hemoptysis

| Antiplatelet and anticoagulant therapy | No       | Yes      | p-value |
|---------------------------------------|----------|----------|---------|
| Recurrence, n (%)                     | 68 (20.1)| 35 (18.8)| 0.72    |
| Recurrence severity, n (%)            |          |          |         |
| Mild                                  | 49 (72.1)| 25 (71.4)| 0.46    |
| Moderate                              | 17 (25.0)| 7 (20.0) |          |
| Severe                                | 2 (2.9)  | 3 (8.6)  |          |
| Median (IQR) n. recurrence events     | 1 (1–2)  | 1 (1–2)  | 0.12    |
| Deaths after 18 months of follow-up, n (%) | 50 (12.6)| 33 (16.0)| 0.24    |
| Deaths for the disease which caused hemoptysis, n (%) | 31 (62.0)| 21 (63.6)| 1.00    |

### Antiplatelet therapy

| Recurrence, n (%) | 80 (20.2) | 23 (18.0) | 0.58 |
|-------------------|-----------|-----------|------|
| Recurrence severity, n (%) |          |          |      |
| Mild              | 59 (73.8) | 15 (65.2) | 0.16 |
| Moderate          | 19 (23.8) | 5 (21.7)  |      |
| Severe            | 2 (2.5)   | 3 (13.0)  |      |
| Median (IQR) n. recurrence events | 1.5 (1–2) | 1 (1–2)  | 0.04 |
| Deaths after 18 months of follow-up, n (%) | 60 (13.0) | 23 (16.0) | 0.37 |
| Deaths for the disease which caused hemoptysis, n (%) | 35 (58.3) | 17 (73.9) | 0.19 |

### Anticoagulant therapy

| Recurrence, n (%) | 91 (19.7) | 12 (19.7) | 0.98 |
|-------------------|-----------|-----------|------|
| Recurrence severity, n (%) |          |          |      |
| Mild              | 64 (70.3) | 10 (83.3) | 0.85 |
| Moderate          | 22 (24.2) | 2 (16.7)  |      |
| Severe            | 5 (5.5)   | 0 (0.0)   |      |
| Median (IQR) n. recurrence events | 1 (1–2)  | 2 (1–2)  | 0.66 |
| Deaths after 18 months of follow-up, n (%) | 71 (13.2) | 12 (18.5) | 0.24 |
| Deaths for the disease which caused hemoptysis, n (%) | 47 (66.2) | 5 (41.7)  | 0.10 |

### Discussion

To the best of our knowledge this is the largest prospective study describing the long-term prognostic outcomes (18 months) of patients with hemoptysis.
An overall mortality rate of 13.7% was found; the number of deaths increased from 18.1–31% after one year of follow-up and, then, decreased to 8.4% at the end of the study period. Most of the deaths occurring during the follow-up were related to the etiology which caused the hemoptysis, with pulmonary neoplasms being the leading cause.

Malignancy, which was reported as the most frequent etiology in patients with hemoptysis in several studies\(^3\)–\(^6\),\(^8\),\(^11\), represents the only significant predictor of mortality in our study.

Hemoptysis related to bronchiectasis, lower respiratory tract infections, and other less frequent etiologies showed a positive prognosis.

Two previous prospective studies based on poor sample size and on a follow-up of 1.8–2.7 years, described a slightly higher mortality rate (19.5–22%)\(^7\),\(^8\), mainly driven by malignancies\(^8\).

More heterogeneous findings were reported by recently published European retrospective studies where lung cancer was the major cause of death, but the mortality rate ranged from 5.9 to 27%\(^2\),\(^6\),\(^10\). Petersen et al. showed that increasing age, previous diagnosis of lung cancer, current/previous smoking history, and concomitant lung diseases are independent risk factors of death\(^10\). Notably, cryptogenic hemoptysis accounted for 80.5% of the diagnoses in this cohort, suggesting a suboptimal or difficult-to-perform diagnostic assessment\(^10\).

Recurrence rate was 17%, with bronchiectasis being the leading cause (27.2%), and the most important predictor of recurrence.

Bronchiectasis recurrences were mainly mild in contrast with those caused by lung malignancies (i.e., the second most frequent cause of recurrence) which were equally mild and moderate.

Few recent retrospective data are available in the scientific literature. According to our findings, Fidan et al. and Ryuge et al., found bronchiectasis as the most frequent diagnosis in recurrent hemoptysis\(^12\),\(^13\). Abdulmalak et al. described a recurrence rate of 16.6% and 16.1% during a 3-year follow-up in 2008 and 2009, respectively\(^2\). Cryptogenic hemoptysis, lower respiratory tract infections, and lung cancer were the most common etiologies of recurrences, with cryptogenic hemoptysis representing 50% of all causes.

Choi et al., who described a recurrence rate of 19.1%, demonstrated that aspergillosis, active bleeding, and blood clot at the bronchoscopy during the first evaluation were significantly associated with the risk of recurrence; however, they analyzed only patients with mild hemoptysis\(^14\). Similar findings were described by Lee et al. who found that active bleeding during bronchoscopy, smoking history > 40 years, and hypertension were the main predictors of recurrence. Notably, the etiology was not evaluated\(^15\).

As suggested by Lee et al. recurrences should alert physicians about undetected pathological findings\(^16\),\(^17\).
In seven patients of our cohort recurrence was associated with a new clinical and radiological assessment and to an etiological change. Three patients initially diagnosed with idiopathic bleedings and pneumonia were subsequently diagnosed with lung cancer, in contrast with the study of Tsoumakidou et al. where lung cancer was not diagnosed in any patients with an initial etiology other than lung cancer. On the contrary, Abdulmalak et al. described a highest rate of lung cancer during the follow-up of patients with a respiratory infection (10.4%)².

In our study, four patients initially diagnosed with acute bronchitis and COPD exacerbation based on clinical and chest X-ray findings were then diagnosed with bronchiectasis.

The present scientific evidence suggests the importance of a clinical and radiological follow-up in patients with bleedings of unknown origin and related to an acute lower respiratory tract infection, as well as a more accurate radiological assessment (i.e., chest CT) in patients with hemoptysis and risk factors for bronchiectasis¹⁹. Very few data can be retrieved on the impact of antiplatelet or anticoagulant therapies on long-term prognostic outcomes. In a large retrospective cohort study, Lee et al. failed to demonstrate a potential role of aspirin on recurrence¹⁵. Similar findings were showed by Ryuge et al. who studied the mechanism of hemoptysis relapse in patients who underwent BAE: they demonstrated that antiplatelet and anticoagulant therapy did not increase recanalization, i.e. the most frequent mechanism underlying re-hemoptysis¹³.

We prospectively proved that these drugs, individually or in combination, did not change the risk of death and of recurrences.

Some study limitations can be found. The observational nature cannot help discriminate the role played by some medical conditions for the background noise of confounders. However, for ethical reasons it is currently the best methodological approach. Differences in some standard operating procedures in the recruited centers could affect some results in terms of diagnostic accuracy. However, the recruited hospitals were reference national centers and, then, the operating variability should be not relevant. Subgroup analyses by etiology could have affected the statistical power of some findings; future studies focused on specific etiologies could confirm our novel results.

**Conclusions**

In conclusion, our study shows a low mortality rate in patients with hemoptysis followed-up for a long period. Pulmonary malignancy is the main etiology and the main predictor of death in these patients, whereas bronchiectasis is the most frequent diagnosis associated with recurrence. Antiplatelet and/or anticoagulant therapy do not change the risk of death or recurrence. Follow-up is recommended in patients initially diagnosed with lower airways infections and those with idiopathic bleedings, to detect new or misdiagnosed lung malignancies.

**Abbreviations**
ml: millilitres
IQR: interquartile ranges
COPD: chronic obstructive pulmonary disease
