Abstract

Adding radion perturbations (up to second order) to the static (RS) metric allows us to calculate the general first and second order interactions of the radion field with the electroweak vector bosons. We use these interactions to compute precision electroweak observables in the case of Higgs-radion mixing and compare with experiment.

1 Introduction

An interesting Brane World Scenario proposed by Randall and Sundrum (RS)\cite{1} involves one extra dimension with warped geometry. This warping can account for the hierarchy between the weak scale and the Planck scale. In this framework the corrections to precision electroweak observables can be described by the Peskin-Takeuchi parameters $S$ and $T$, and can come both from the Higgs-radion sector\cite{2,3,4} and from the Kaluza Klein excitations sector\cite{5}. Here we would like to refine and expand upon precision electroweak constraints on the Higgs-radion sector\cite{6}, focusing on those regions of parameter space for which the KK excitations are too massive to have significant $S$ and $T$ contributions.

Ignoring tensor perturbations, the metric of the five-dimensional space can be written up to quadratic terms in the radion $r(x)$ as

$$
\begin{align*}
\frac{d\ell^2}{ds^2} &= \left[ e^{-2\sigma} &\eta_{\mu\nu} - \tilde{\kappa} \{ \eta_{\mu\nu}, c(y) r(x) \} - \tilde{\kappa}^2 \eta_{\mu\nu} e^{2\sigma} a(y) r^2(x) \right] dx^\mu dx^\nu \\
&+ \left[ 1 + \tilde{\kappa}^2 e^{2\sigma} c(y) r(x) + \tilde{\kappa}^2 e^{4\sigma} f(y) r^2(x) \right] dy^2
\end{align*}
$$

(1)

where $\tilde{\kappa}^2 = M_{Pl}^{-3}$ and $r(x)$ is the non-canonically normalized radion field. In the unphysical case of no radion stabilization (i.e., no radion mass) $\sigma(y) = k y$ (in the bulk), $c(y) = c(y) = 1$, $a(y) = 1/4$ and $f(y) = 2$ (no $\partial_n r \partial^\mu r$ trilinear self
interactions in this limit). We assume that all the Standard Model particles live on the “SM brane” at $y = y_0$. On the other hand, the graviton wave function is peaked at the “Planck brane” at $y = 0$.

The interactions of the canonically normalized radion $\phi_0$ with the SM vectors, up to order $\phi_0^2$, are

$$L_{\text{int}}(\hat{\kappa}^1) = -\left(\frac{1}{\Lambda_\phi}\right) \phi_0 \left[M_V^2 V^\alpha V_\alpha - \epsilon L_V\right]$$

(2)

$$L_{\text{int}}(\hat{\kappa}^2) = \frac{4}{\Lambda_\phi^2} \phi_0^2 \left[\frac{\eta}{2} M_V^2 V^\alpha V_\alpha - \epsilon \left(\frac{(2\eta - 1)}{4} L_V + \frac{1}{4} M_V^2 V^\alpha V_\alpha\right)\right]$$

(3)

where $L_V$ is the usual Lagrangian density of a massive vector field. $\Lambda_\phi$ sets the strength of these interactions, and should be of order $\approx 1$ TeV. We have also defined $\eta = a(y_0)/c(y_0)^2$ which should be of order unity. The $\epsilon$ in the above equations is a remnant of the dimensional regularization requirement of working in $D = 4 - \epsilon$ dimensions.

There may exist a Higgs-radion mixing term $L = \xi \partial h_0 \partial \phi_0$ derived from the SM-brane operator

$$L = \xi \int d^4x \sqrt{g_{\text{ind}}} R(g_{\text{ind}}) H^\dagger H.$$  

(4)

The mass eigenstates $h$ and $\phi$ can be obtained from the “geometry eigenstates” $h_0$ and $\phi_0$ by suitable field redefinitions\cite{2, 8}. The interactions between these new physical fields and the electroweak vector bosons will be altered by this mixing.

\section{2 Precision electroweak constraints}

We can now compute the $S$ and $T$ parameters, both of which have several types of contributions. First, we have direct contributions of each eigenstate of the Higgs-radion system. There are also contributions from the so-called “anomalous terms” coming from the $\epsilon$ terms in (2) and (3). Finally, we also expect non-renormalizable operators to contribute. Naively one could expect these operators to be suppressed by powers of $M_{\text{Pl}}^{-1}$. However as a consequence of the warped geometry, the actual suppression is by powers of $\Lambda_\phi^{-1}$.

As shown in Fig.\ref{fig1}, when the physical eigenstate masses $m_h$ and $m_\phi$ are both relatively modest in size, precision electroweak constraints disfavor\thinspace\footnote{To account for these effects, we basically follow Ref\cite{2}}\thinspace$\xi$ wings of the theoretically allowed hourglass-shaped region in the $(\xi, m_\phi)$ plane. The dependence on the parameter $\eta$ is minimal.

\footnotetext[1]{To account for these effects, we basically follow Ref\cite{2}}

\footnotetext[2]{In order to determine the allowed regions of $S, T$ parameter space, we have employed a $\chi^2$ ellipse parameterization.}
We now consider large scalar masses, and large values of the mixing parameter $\xi$. In Fig. 2 we fix $m_h = 350$ GeV, $\xi = -2$ (left) and $m_h = 650$ GeV, $\xi = -4$ (right), and show 90% confidence level contours of allowed regions and disallowed regions in the $m_\phi - \Lambda_\phi$ plane.

The lightly shaded tower in this figure is “theoretically excluded” because it is impossible for both mass eigenstates to exist for the particular set of input values (one of the fields becomes a ghost). The darker (red) shaded regions are allowed by precision electroweak data. These regions are characterized by $\Lambda_\phi$ near the theoretically allowed minimum value and $m_\phi$ somewhat near the Higgs mass. We see that an extraordinarily heavy radion mass compared to the Higgs mass is too disruptive to the $S$-$T$ fits.

When increasing the Higgs mass with fixed $\xi$, the large $m_\phi$ allowed region tends to disappear. But, as shown in the right panel of Fig. 2 we recover a region compatible with precision electroweak data constraints with a larger value of $|\xi|$. Results for $\xi > 0$ are similar in nature.

Varying the parameter $\eta$ changes somewhat the form of the allowed regions, but this does not affect the general conclusion that a heavy Higgs boson mass and a heavy radion can both be above the putative Higgs mass upper limit from precision electroweak data.
