Abstract

Within the Büttiker dephasing model, the backscattering in the dephasing process is eliminated by setting a proper boundary condition. Explicit expression is carried out for the effective total tunneling probability in the presence of multiple pure dephasing scatterers with partial coherence. The derived formula is illustrated analytically by various limiting cases, and numerically for its application in tunneling through multi-barrier systems.

PACS numbers:73.23.-b,73.40.-c
To simulate the phase-breaking effect in partially coherent transport through a mesoscopic system, Büttiker proposed a conceptually simple model by coupling electronic reservoirs to the conductor. The dephasing reservoir can be thought of as either a fictitious or a real branch voltage probe. Although this approach appears to be purely phenomenological, it however can be justified from a microscopic theory with proper approximations by viewing that both the electron-phonon interactions and the dephasing reservoir can be described by a self-energy function. Owing to the simplicity, the Büttiker dephasing model has received noticeable attention and been applied to transport through various mesoscopic systems.

Noticeably, in the original work of Büttiker and the later applications mentioned above, in addition to randomizing the electronic phase, the phase-breaking scatterer would also randomize the electronic momentum. Randomization of momentum means backscattering in the dephasing process, thus introduces an additional resistance. This undesired feature has been noticed and analyzed by a few authors commonly following the idea by coupling two voltage probes to model a single pure dephasing scatterer. In this paper, based on the original work of Büttiker (i.e. using a single reservoir to model a single dephasing scatterer), an explicit expression will be derived for the effective total tunneling probability through a multi-barrier mesoscopic system in the presence of multiple pure dephasing scatterers with arbitrary dephasing strength. The underlying physics and practical application will be illustrated clearly.

In general, consider the tunneling through a series of barriers shown in Fig. 1, where the squares stand for tunnel barriers, and the triangles for dephasing scatterers. They can be described in terms of scattering matrices as follows. For the individual (symmetric) barrier (e.g. the $j$th one), the tunneling property is characterized by

$$S_{el}^j = \begin{bmatrix} r_j & t_j \\ t_j & r_j \end{bmatrix},$$

which connects the two incoming amplitudes with the two outgoing amplitudes as is well known. $t_j$ and $r_j$ are respectively the transmission and reflection coefficients through the
barrier, and can be characterized by a real parameter \((0 \leq \delta_j \leq 1)\) as \(t_j = \sqrt{\delta_j}\), and \(r_j = i\sqrt{1 - \delta_j}\). For each dephasing scatterer, following Büttiker’s approach\(^1\)\(^2\), a dephasing reservoir is coupled to the system via two channels. During tunneling process, the electron has certain quantum probability of being scattered into the reservoir, undergoing phase randomization in it, then returning into the system via the coupler. As a result of dephasing, the re-emitted component does not interfere with that having not entered the reservoir. As a specific model, the coupler is described by the following scattering matrix\(^3\)\(^4\)

\[
S = \begin{pmatrix}
0 & \sqrt{1 - \epsilon} & \sqrt{\epsilon} & 0 \\
\sqrt{1 - \epsilon} & 0 & 0 & \sqrt{\epsilon} \\
\sqrt{\epsilon} & 0 & 0 & -\sqrt{1 - \epsilon} \\
0 & -\sqrt{1 - \epsilon} & 0 & 0
\end{pmatrix}
\]

This 4×4 matrix connects the 4 incoming amplitudes with the 4 outgoing amplitudes along the attached 4 channels. Here, \(\epsilon \in [0, 1]\) is a parameter characterizing the dephasing strength ranging from complete coherence to complete incoherence.

To carry out the effective tunneling probability from channel 1 to channel 2 shown in Fig. 1, the \((2N + 2) \times (2N + 2)\) S-matrix \(S^{(N)}\) of the entire system is needed. Note that the dimension of \(S^{(N)}\) corresponds to the total number of external channels. By applying either a direct matrix algebra or the Feynman path technique, \(S^{(N)}\) can be carried out via the following recursive expressions:\(^5\)\(^6\)

\[
S_{ij}^{(N)} = \tilde{s}_{ij}^{(N)} \left[ Z_N \chi \right] S_{2i}^{(N-1)} ,
\]

\[
S_{ji}^{(N)} = S_{i2}^{(N-1)} \left[ Z_N \chi \right] \tilde{s}_{i1}^{(N)} ,
\]

\[
S_{1j}^{(N)} = S_{12}^{(N-1)} + S_{12}^{(N-1)} \left[ Z_N \chi \tilde{s}_{11}^{(N)} \right] S_{2j}^{(N-1)} ,
\]

\[
S_{ij}^{(N)} = s_{ij}^{(N)} + s_{ij}^{(N)} \left[ Z_N \chi \tilde{s}_{22}^{(N-1)} \chi \right] \tilde{s}_{ij}^{(N)} .
\]

Here \(I, J = 1, 3, 4, \ldots, 2N - 1, 2N\), and \(i, j = 2, 2N + 1, 2N + 2\). \(S_{i}^{(N-1)}\) is the scattering matrix for the subsystem of \(N\) tunnel barriers (correspondingly, \(N-1\) dephasing scatterers); and the 4×4 scattering matrix \(\tilde{s}^{(N)}\) is for the \(N\)th single scatterer–barrier segment. \(Z_N = \)
\[ [1 - \chi S_{22}^{(N-1)} \chi S_{11}^{(N)}]^{-1}, \text{ resulting physically from the multiple reflections.} \]

\( \chi \) denotes the plane-wave propagation-induced phase-change factor for the electron moving between the two composite subsystems. For simplicity, we hereafter set \( \chi = 1 \), which is valid for far off-resonance tunneling.

In practice of computing the S-matrix of the entire system, we start with \( S^{(1)} \) for the simple system of barrier-scatterer-barrier. Applying the recursive technique described above and making use of Eqs. (1) and (2), we obtain

\[
S^{(1)} = Z_1 \begin{bmatrix}
r_1 + \alpha^2 r_2 & \alpha t_1 t_2 & \beta t_1 & \alpha \beta t_1 r_2 \\
\alpha t_1 t_2 & r_2 + \alpha^2 r_1 & \alpha \beta r_1 t_2 & \beta t_2 \\
\beta t_1 & \alpha \beta r_1 t_2 & \beta^2 r_1 & -\alpha (1 - r_1 r_2) \\
\alpha \beta t_1 r_2 & \beta t_2 & -\alpha (1 - r_1 r_2) & \beta^2 r_2
\end{bmatrix}.
\]

Here \( \alpha = \sqrt{1 - \epsilon} \) and \( \beta = \sqrt{\epsilon} \) are introduced to simplify the notation, and \( Z_1 = (1 - \alpha^2 r_1 r_2)^{-1} \). The most important advantage of the present technique is its ability in treating multiple dephasing scatterers. To this end, we need the S-matrix of the added segment of scatterer-barrier. It can be easily obtained from Eq. (4) by setting \( r_1 = 0 \) and \( t_1 = 1 \), and replacing \( t_2 \) (\( r_2 \)) by \( t_j \) (\( r_j \)) for the \( j \)th coherent barrier. We denote the resulting \( 4 \times 4 \) S-matrix by \( \tilde{s}^{(j)} \) [c.f. Eq. (3)]. Using Eq. (4) and the recursive rules of Eq. (3), we can therefore evaluate the S-matrix \( S^{(N)} \) for the entire system, thus calculate the effective tunneling probability through the system (i.e. from channels 1 to 2). In the following, for the convenience of comparison, we first present result under the momentum randomization boundary condition. Then, the formal result and its implication/application based on the pure dephasing boundary condition are carried out comparatively.

**Momentum Randomization Boundary Condition.** Under this boundary condition, the re-emitting current from the \( n \)th reservoir into the system is assumed to be equally injected through its \( (2n + 1) \)th and \( (2n + 2) \)th channels. We denote this current as \( \tilde{J}_n \). In the dephasing process, the electron number is conserved, thus the net current of the two channels connecting the system and the reservoir is zero. This feature is characterized by
\[(2\mathbf{I} - \mathbf{T})\mathbf{J}_B = \mathbf{K}^{(1)} J_L, \tag{5}\]

where \(\mathbf{I}\) is the \(N \times N\) unit matrix, and \(\mathbf{J}_B = (\bar{J}_1, \bar{J}_2, \cdots, \bar{J}_N)^T\). Hereafter the superscript \((\cdots)^T\) means transposition of matrix. \(J_L\) is the current injected from the left channel 1. \(\mathbf{T}\) is a \(N \times N\) matrix with elements \(T_{nm} = T_{2n+1,2m+1} + T_{2n+1,2m+2} + T_{2n+2,2m+1} + T_{2n+2,2m+2}\), where \(T_{ij} \equiv T_{ij} = |S_{ij}|^2\). \(\mathbf{K}^{(1)}\) is a \(N \times 1\) matrix with elements \(K_n^{(1)} = T_{2n+1,1} + T_{2n+2,1}\).

Substituting the formal solution of Eq. (5), we consider in more detail the scattering on the dephasing scatterer (e.g. the pure dephasing condition). To elucidate this boundary condition, let us consider in more detail the scattering on the dephasing scatterer (e.g. the pure dephasing condition), see Fig. 2. The scattering matrix \(\mathbf{S}\) of Eq. (2) relates the outgoing amplitudes \(\mathbf{a}'_n = (a'_{2n+1}, a'_{2n+2}, b'_{2n+1}, b'_{2n+2})^T\) to the incoming amplitudes \(\mathbf{a}_n = (a_{2n+1}, a_{2n+2}, b_{2n+1}, b_{2n+2})^T\) in terms of \(\mathbf{a}'_n = \mathbf{S}_n a_n\). It is easy to check that the unitary property of \(\mathbf{S}_n\) and its specific structure would lead to the conserving relations

\[
|a'_{2n+1}|^2 + |b'_{2n+2}|^2 = |a_{2n+2}|^2 + |b_{2n+1}|^2, \tag{7a}\]
\[
|a'_{2n+2}|^2 + |b'_{2n+1}|^2 = |a_{2n+1}|^2 + |b_{2n+2}|^2. \tag{7b}\]

Now we make use of the pure dephasing condition: \(|a_{2n+1}|^2 = |a'_{2n+1}|^2\), and \(|a_{2n+2}|^2 = |a'_{2n+2}|^2\). Its physical meaning is quite clear by noting that the phase-breaking only randomizes the phases of the forward and backward going waves, but does not cause any reflections. Because of this nature, we term it as a backscattering-free boundary condition, which straightforwardly leads to

\[
|b'_{2n+1}|^2 = |b_{2n+2}|^2, \tag{8a}\]
\[
|b'_{2n+2}|^2 = |b_{2n+1}|^2. \tag{8b}\]
With this physical insight, we are ready to derive the effective tunneling probability under the present boundary condition. We denote \( J_n = (j_{2n+1}, j_{2n+2})^T \) for the injecting currents from the \( n \)th reservoir into the system via the \((2n + 1)\)th and \((2n + 2)\)th channels, and \( J'_n = (j'_{2n+1}, j'_{2n+2})^T \) for the currents being scattered into the reservoir from the system via the same channels. The pure dephasing boundary condition, now denoted as \( j'_{2n+1} = j_{2n+2} \), and \( j'_{2n+2} = j_{2n+1} \), can be expressed compactly for all the \( N \) reservoirs as

\[
J'_B = \mathbf{B} J_B,
\]

where \( J_B = (J_1, J_2, \cdots, J_N)^T \), \( J'_B = (J'_1, J'_2, \cdots, J'_N)^T \), and \( \mathbf{B} = \mathbf{I} \otimes \mathbf{\sigma} \). \( \mathbf{\sigma} \) is a \( 2 \times 2 \) matrix with elements \( \sigma_{ij} = 1 - \delta_{ij} \). Again, a simple current counting leads to:

\[
J_R = T_{21} J_L + \mathbf{K}^{(2)} J_B, \quad (10a)
\]

\[
J'_B = \mathbf{K}^{(1)} J_L + \mathbf{T} J_B. \quad (10b)
\]

Here, \( \mathbf{K}^{(1)} \) is a \( 2N \times 1 \) matrix with elements \( T_{n1} \), and \( \mathbf{K}^{(2)} \) an \( 1 \times 2N \) matrix with elements \( T_{2n} \), with \( n = 3, 4, \cdots, 2N + 2 \). \( \mathbf{T} \) is a \( 2N \times 2N \) matrix with elements \( T_{mn} \), with \( m, n = 3, 4, \cdots, 2N + 2 \). Straightforwardly, by substituting Eq. (9) into Eq. (10) an elegant expression is obtained for the effective tunneling probability

\[
T_{\text{eff}} \equiv J_R/J_L = T_{21} + \mathbf{K}^{(2)} (\mathbf{B} - \mathbf{T})^{-1} \mathbf{K}^{(1)}. \quad (11)
\]

This equation is formally similar to Eq. (3). Both Eqs. (3) and (11) contain a common coherent term (the first one), and an incoherent term (the second one). However, they physically differentiate from each other. Below we detail our discussions on their difference by focusing on the special case of one dephasing scatterer.

In the case of \( N = 1 \), from Eq. (3) we easily obtain

\[
\tilde{T}_{\text{eff}} = T_{21} + (T_{23} + T_{24}) (2 - \tilde{T}_{11})^{-1} (T_{13} + T_{14})
= T_{21} + S_b S_f / (S_b + S_f). \quad (12)
\]

Here, following Büttiker\(^1\)\(^2\) the incoherent backward and forward scattering probabilities are introduced: \( S_b = T_{13} + T_{14} \), and \( S_f = T_{23} + T_{24} \). In deriving Eq. (12), the symmetry
\( T_{mn} = T_{nm} \) and the sum rule \( \sum_m T_{mn} = 1 \) have been used. On the other hand, for \( N = 1 \), Eq. (11) leads to

\[
T_{\text{eff}} = T_{21} + [(T_{44}T_{23}T_{31} + T_{33}T_{24}T_{41}) \\
+ (1 - T_{34})(T_{23}T_{41} + T_{24}T_{31})]/Z,
\]

(13)

where \( Z = (1 - T_{34})^2 - T_{33}T_{44} \).

Further, in the completely incoherent regime \( (\epsilon = 1) \), \( T_{13} = T_1 \equiv |t_1|^2 \), \( T_{24} = T_2 \equiv |t_2|^2 \), \( T_{33} = 1 - T_1 \), and \( T_{44} = 1 - T_2 \). Other \( T_{mn} \) in Eqs. (12) and (13) are zero. In this regime, Eq. (12) reduces to

\[
\tilde{T}_{\text{eff}} = \left[ \frac{1}{T_1} + \frac{1}{T_2} \right]^{-1},
\]

(14)

whereas Eq. (13) gives rise to

\[
T_{\text{eff}} = \left[ \frac{1}{T_1} + \frac{1}{T_2} - 1 \right]^{-1}.
\]

(15)

The latter equation (15) can also be obtained by a rather simple treatment based on incoherent multiple reflections and transmissions through two barriers. The interesting difference between Eqs. (14) and (13) is highlighted as follows. It is well known that the two-terminal resistance is related to the effective total transmission probability \( T_{\text{tot}} \) (i.e. \( \tilde{T}_{\text{eff}} \) and \( T_{\text{eff}} \)) via the Laudau formula, \( R_{\text{tot}} = (h/e^2)(1/T_{\text{tot}}) \). From Eq. (14) the system resistance can be expressed as

\[
\tilde{R}_{\text{tot}} = R_1 + R_2 + R_c + R_s.
\]

(16)

In this decomposed form, \( R_j = (h/e^2)(1 - T_j)/T_j \) \( (j = 1, 2) \) is the Landauer resistance for the \( j \)th conductor, \( R_c = h/e^2 \) is the so-called contact resistance rooted in the two-terminal configuration (measurement). Interestingly, the dephasing scatterer contributes a constant resistance \( R_s = h/e^2 \) in the completely incoherent regime, due to the momentum randomization. On the other hand, from Eq. (13) we have

\[
R_{\text{tot}} = R_1 + R_2 + R_c.
\]

(17)
We see that under the boundary condition Eq. (9) the dephasing scatterer only plays a phase-breaking role. As a result, the Landauer resistances are connected in series in a purely classical way, and the dephasing source does not cause additional resistance.

Interestingly, the backscattering-free nature on the dephasing scatterer can be further elucidated by considering the simple transmission through only a dephasing scatterer (i.e. with no tunnel barriers), with arbitrary dephasing strength. In this case, the relevant transmission coefficients are: $T_{21} = T_{34} = 1 - \epsilon$, $T_{13} = T_{24} = \epsilon$, $T_{33} = T_{44} = T_{14} = T_{23} = 0$. Accordingly, Eq. (12) gives rise to $\tilde{T}_{\text{eff}} = 1 - \epsilon/2$, whereas Eq. (13) leads to $T_{\text{eff}} = 1$. This result clearly shows the distinct nature of the two dephasing models: one causes backscattering, another is backscattering free.

For two resistors connected in partial coherence ($0 < \epsilon < 1$), the simple sum rule of the individual resistances as Eqs. (16) and (17) breaks down. However, the resistance difference $\Delta R = (h/e^2)(1/\tilde{T}_{\text{eff}} - 1/T_{\text{eff}})$ based on Eqs. (12) and (13) is a proper quantity to characterize the additional resistance caused by the dephasing scatterer under the momentum-randomization boundary condition. Figure 3 shows $\Delta R$ as a function of the dephasing strength $\epsilon$. In general, the interplay between the backscattering on the dephasing scatterer and the tunneling through the individual barriers leads to $\Delta R(\epsilon)$ depending on the barrier-tunneling strength as shown in Fig. 3.

To further illustrate the application of Eqs. (6) and (11) in combination with the recursive rule of Eq. (3), we briefly present results for tunneling in the presence of multiple phase-breaking scatterers. For clarity, Figure 4 shows the relative tunneling probabilities versus the dephasing strength, i.e., $T_{\text{eff}}(\epsilon)/T_{\text{eff}}(\epsilon = 0)$ and $\tilde{T}_{\text{eff}}(\epsilon)/\tilde{T}_{\text{eff}}(\epsilon = 0)$, by solid and dashed curves, respectively. In the weak tunneling regime ($\delta = 0.1$) shown in Fig. 4(a), dephasing enhances the tunneling remarkably, and the two dephasing models, i.e., Eqs. (6) and (11), give almost the same results. However, in the strong tunneling regime ($\delta = 0.9$) shown in Fig. 4(b), the two dephasing models give noticeably different results. More interestingly, the turnover behavior predicted by Eq. (6), which was paid special attention by Büttiker, does not occur in the pure dephasing model of Eq. (11). Therefore, the turnover behavior appears
a consequence of competition between the incoherent-tunneling and the dephasing-induced backscattering. It disappears after the backscattering being eliminated.

In summary, we have presented a unified treatment for phase-breaking tunneling based on the Bütiker model. Simple adopting of two types of boundary conditions can clear up the distinct natures of two dephasing models. The derived explicit expressions in combination with the recursive rules can be conveniently applied to tunneling through multi-barrier systems in arbitrary partial coherence.
