Conclusion. Granger causality tests are commonly used in economic modeling but have not been routinely applied to infectious diseases. Using this test, we found a strong correlation between weekly cases of hospitalized influenza and iGAS septic shock or pneumonia. This approach can provide insight into the potential impact of developing prevention interventions for infectious disease transmission. Further exploration of Granger tests in infectious disease modeling should be considered.

Buiting, BS; Crystalynne Bell, BA; Erik Reisford, MPH; Peter Shult, PhD; Mary Wedg, BS; Thomas Haupt, MS; James Conway, MD FAAP; Ronald Gangnon, PhD; Ashley Fowlkes, MPH; and Amara Uzcain, MD, MPH; Family Medicine, University of Wisconsin School of Medicine and Public Health, Madison, Wisconsin, 2Department of Biostatistics and Medical Informatics, School of Medicine and Public Health, University of Wisconsin – Madison, Madison, Wisconsin, 3Pediatrics, University of Wisconsin School of Medicine and Public Health, Madison, Wisconsin, 4Department of Biostatistics and Medical Informatics, School of Medicine and Public Health, University of Wisconsin – Madison, Madison, Wisconsin, 5Influenza Division, Centers for Disease Control and Prevention, Atlanta, Georgia, 6Communicable Disease Division, Wisconsin State Laboratory of Hygiene, Madison, Wisconsin, 7Bureau of Communicable Diseases, Wisconsin Division of Public Health, Madison, Wisconsin, 8Pediatrics, University of Wisconsin School of Medicine and Public Health, Madison, Wisconsin, 9Department of Biostatistics and Medical Informatics, School of Medicine and Public Health, University of Wisconsin – Madison, Madison, Wisconsin

Session: 66. Public Health: Epidemiology and Outbreaks Thursday, October 4, 2018: 12:30 PM

Background. Schools are purported to be primary venues of influenza transmission and amplification with secondary spread to communities. We assessed K–12 student absenteeism monitoring as a means for early detection of influenza activity in the community.

Methods. We conducted a 3-year, prospective observational study of all-cause (a-TOT), illness-associated (a-I), and influenza-like illness-associated (a-ILI) absenteeism within the Oregon School District, Oregon, WI (OSD: enrollment = 3,900 students). Absenteeism reporting was facilitated by automated processes within OSD’s electronic student information system. Students were screened for ILI, and, if eligible, visited at home, where pharyngeal specimens were collected for influenza RT-PCR (IVD CDC Human Influenza Virus RT-PCR Diagnostic Panel) and multipathogen testing (Luminex NxTAG RPP). The study definition of a-ILI was validated for 700 children with acute respiratory infections using binomial logistic regression. Surveillance of medically attended respiratory infections using Poisson general additive log linear regression models of daily cases. Results. Influenza A and B were detected in 54 and 51 of the 700 visited students, respectively. A positive correlation of influenza status with a-ILI absenteeism was significantly associated with a-ILI status (OR = 4.74; 95% CI: 2.78—8.18; P <0.278; P <0.001). Of MI4 patients, 371 had influenza A and 143 had influenza B. a-ILI was significantly correlated with MAI in the community (r = 0.472; P <0.001) with a 15-day lead time. a-ILI was significantly correlated with MAI in the community (r = 0.480; P <0.001) with a 1-day lead time. a-TOT performed poorly (r = 0.278; P <0.001), following MAI by 9 days (Figure 1).

Conclusion. Surveillance using case-specific absenteeism was feasible to implement in OSD and performed well over a 3-year period marked by diverse presentations of seasonal influenza. Monitoring a 1- and a-ILI can detect influenza outbreaks in the community, providing early warning in time for community mitigation efforts for seasonal and pandemic influenza.

687. Modeling the Impact of Introduction of Influenza Vaccination on ILI Cumulative Case Count in Cameroon

Uebal Tamoufe, MPH, MS; Nancy Ortiz, MPH, PhD candidate; Karen Saylors, PhD; Matt LeBreton, MS; Viviane Mejuga, MS; Cyrille Djoko, PhD; and Richard Njouom, PhD; 1Metabiota Cameroon, Yaoundé, Cameroon, 2Metabiota, San Francisco, California, 3Mosaic, Yaoundé, Cameroon

Session: 66. Public Health: Epidemiology and Outbreaks Thursday, October 4, 2018: 12:30 PM

Background. Influenza illness can range from mild to severe, with serious outcomes occurring in children and the elderly. Flu has been studied extensively in geographies where vaccine is often plentiful. The burden of influenza is not well known in tropical regions where vaccine coverage is scant. Our study examines the impact of introducing flu vaccination in tropical regions with <0.2% influenza vaccine utilization

Methods. The data consists of 1 year of flu surveillance from patients presenting with influenza-like illness at clinics in Cameroon. Samples underwent RT-PCR influenza screening. Analysis was performed in Berkeley Madison. We developed ordinary differential equations (ODEs) and calculated R0.

Results. We estimated the proportion of cases the clinics observed to make inferences to the capture population of these health facilities. We developed another set of ODEs to introduce vaccination using a pulse function with a 50% efficacy and 45% vaccination coverage.

Conclusion. We observed vaccination at 45% coverage (US average). Cameroon would likely achieve reduced coverage. Therefore, we examined introducing vaccination with 10% coverage, and observed that flu cases were cut by over one third.

688. Impact of Expanded Influenza Post-exposure Prophylaxis on Healthcare Worker Absenteeism at a Tertiary Care Center During the 2017–2018 Season

Mireia Puig Asensio, MD, PhD; Margaret Douglas, RKT, MPH; Stephanie Holley, MBA, BSN; Mary Beth Kukla, BSN, RN; Oluchi Abosi, MPh, MBChB; Lisa Mascaro, PharmD; Brenda Carmody, BS Pharm RPh; Courtney Gent, PharmD; Danielle Diekema, MD, FIDSA, FSHEA; Patrick Hartley, MD, MPH; Michael Edmond, MD, MPH, MPA, FIDSA, FSHEA and Jorge L. Schemmel, MD

Session: 66. Public Health: Epidemiology and Outbreaks Thursday, October 4, 2018: 12:30 PM

Background. A severe 2017–2018 influenza season was expected for the United States. We hypothesized that a surge in influenza cases paired with decreased vaccine effectiveness could increase healthcare worker (HCW) absenteeism. Because of a potential public health emergency during the 2017–2018 season, we offer oseltamivir post-exposure prophylaxis (PEP) to exposed HCWs regardless of vaccination status. We describe PEP uptake, cost, and impact on absenteeism at the University of Iowa Hospital and Clinics (UIHC).

Methods. UIHC serves as a referral and safety net health system for Eastern Iowa. Influenza seasons were defined as the period between Week 40 from 1 year to Week 13 of the following year. The 2016–2017 season, PEP (75 mg/day for 10 minutes without mask protection, or direct contact with respiratory secretions. Exposure was defined as proximity within 3 ft of a confirmed influenza-infected person for ≥ 10 minutes without mask protection, or direct contact with respiratory secretions. During the 2017–2018 season, PEP was expanded to all exposed HCWs regardless of vaccination status. We reviewed surveillance, employee health, pharmacy, and human resources records for the 2016–2017 and 2017–2018 seasons. We defined PEP uptake as prescriptions picked up/all referrals and absenteeism rate as sick-leave requests/scheduled hours.

Results. The 2016–2017 and 2017–2018 seasons, we detected 375 and 427 confirmed influenza cases among patients at UIHC. HCW vaccination rates were similar: 89.7% and 90.9%. PEP was recommended in 49 exposures during 2016–2017 and 280 exposures during 2017–2018. A total of 22 (44.9%) and 133 (47.5%) HCWs picked up oseltamivir from the pharmacy during the 2016–2017 and 2017–2018 seasons. The estimated cost of oseltamivir was $1,794 and $10,828, respectively. Overall, 6,187 sick-leave requests (median = 12 hours, absenteeism rate = 3.2%), and 6,174 sick-leave requests (median = 12 hours, absenteeism rate = 3.4%) were reported during the 2016–2017 and 2017–2018 seasons.

Conclusion. Influenza case counts mildly increased from the 2016–2017 to the 2017–2018 season. Expanding PEP to all exposed HCWs, regardless of vaccination status, had moderate uptake and was costly. Absenteeism rates remained similar during both seasons.
