Motivation for Precision Physics

Although many cosmological (and not only) results indicate the need of BSM physics:

- Dark Matter and Dark Energy
- Neutrino Oscillations
- Matter - Antimatter asymmetry
- Quantum Gravity incorporation

there is no striking manifestation of New Physics beyond the SM at the LHC, as this can be found by the comparison of the measurements with the theoretical predictions!

The upgrading of LHC and the establish of future experiments will result to more accurate measurements and will require more accurate theoretical predictions!

Thus Precision pQCD, which provides highly precise theoretical predictions for the SM, becomes a necessity for the discovery of BSM physics via deviation from the Standard Model! Current frontier:

- NNLO for $2 \rightarrow 3$ processes
- $N^3$LO for $2 \rightarrow 2$ processes
- $N^4$LO for $2 \rightarrow 1$ processes

Moreover the study of Precision pQCD has led to many developments to other domains such as Theory of Special Functions, Computer Algebra, Algebraic Geometry etc.
Cross sections

• The cross section for the collision of 2 initial hadrons \((h_1, h_2)\) to some final state \(X\) is

\[
d\sigma_{h_1 h_2 \rightarrow X} = \sum_{a, b = q, \bar{q}, g} \int_{x_1, \text{min}}^{1} dx_1 \int_{x_2, \text{min}}^{1} dx_2 \mathcal{F}_{a/h_1}(x_1, \mu^2) \mathcal{F}_{b/h_2}(x_2, \mu^2) \hat{\sigma}_{ab \rightarrow X}(\mu^2)
\]

where \(\mathcal{F}_{a/h_1}\) and \(\mathcal{F}_{b/h_2}\) are the Parton Distribution Functions, \(\hat{\sigma}_{ab \rightarrow X}\) is the hard-part cross section, and \(\mu^2\) is the factorization scale.

• \(\hat{\sigma}_{ab \rightarrow X}\) at NNLO receives contributions from three different sources (virtual, mixed real-virtual, and doubly-real corrections)

\[
d\hat{\sigma}_{ab \rightarrow X}^{\text{NNLO}} \sim |\mathcal{M}_{\text{tree}}|^2 + \alpha_S \left( \text{Re} \left[ \mathcal{M}_{\text{tree}} \mathcal{M}_{\text{loop}}^* \right] + |\mathcal{M}_{+1up}|^2 \right) + \alpha_S^2 \left( |\mathcal{M}_{\text{loop}}|^2 + \text{Re} \left[ \mathcal{M}_{\text{tree}} \mathcal{M}_{2\text{loops}}^* + \mathcal{M}_{+2up} \mathcal{M}_{+1up}^* \right] + |\mathcal{M}_{+2up}|^2 + \text{Re} \left[ \mathcal{M}_{+1up+\text{loop}} \mathcal{M}_{+1up}^* \right] \right)
\]

Each of these contributions is individually divergent, and the divergences cancel in the sum (after renormalization for the UV and IR divergences) leaving behind the finite result for the cross section.

A lot of effort is needed in all the steps for the calculation of the cross section. Nonetheless, from the above expression the most difficult part to be calculated has been proved to be the 2-loop amplitude, \(\mathcal{M}_{2\text{loops}}\)!
Recent Results for 2-loop Amplitudes

Impressively in the last years, some results have appeared in the literature for different 2-loop $2 \to 3$ scattering amplitudes, applying different approaches for the amplitude reduction (Numerical Unitarity, Projectors etc)

- **Leading color:** $gg \to ggg, q\bar{q} \to ggg, q\bar{q} \to q\bar{q}g, q\bar{q} \to \gamma\gamma\gamma$, and $q\bar{q} \to g\gamma\gamma$.
- **Full color:** $gg \to ggg$ (all-plus helicities) and $q\bar{q} \to g\gamma\gamma$.

Structure of an (2-loop) Amplitude

The construction and calculation of a (2-loop) Amplitude, \( \mathcal{A} \), contains the following steps:

1. **Use of SM Feynman Rules to Generate the Feynman Graphs contributing to the process at hand.**
2. **Collect all the above contributions and create the Amplitude.**
3. **Integrand/Integral Reduce the Amplitude into a set of Master (Feynman) integrals, determining their coefficients.**
4. **Calculate analytically or numerically the Master Integrals (see talk of Syrrakos).**

The final result is of the form

\[
\mathcal{A} = \sum_i c_i(s, \varepsilon) F_i(s, \varepsilon) \quad (3.1)
\]

where \( c_i \) are rational/algebraic coefficients obtained by the Amplitude reduction and they depend by the process at hand, \( F_i \) can be Master Integrals or special functions (Multiple Polylogarithms\(^1\), Pentagon Functions\(^2\), Elliptic Integrals, etc) that depend from the kinematics and are process-independent, and \( s \) are the Mandlestam variables.

Quick Review of HELAC-1LOOP

Any 1-loop $n$-particle (color-stripped) amplitude can be written in the form

$$ A = \int d^d k \ A = \sum_{I \subset \{1, \ldots, n\}} \int \frac{\mu^{(4-d)}}{(2\pi)^d} \frac{N_I(k, p_1, \ldots, p_{n-1}, \gamma^\mu, \epsilon^\mu)}{\prod_{i \in I} D_i} $$

where $N_I$ is the numerator and $D_i = (k + p_i)^2 + m_i^2$ the propagators. The loop momentum "lives" in $d$ dimensions and can be decomposed as

$$ k = \overline{k} + k^* \quad \text{with} \quad \overline{k}: 4-\text{dimensional} \quad \text{and} \quad k^*: \varepsilon-\text{dimensional}. $$

In order to compute $A$ we need to cast it in to the following well-known form at $d \to 4$

$$ A = \sum_i d_i \ Box_i + \sum_i c_i \ Triangle_i + \sum_i b_i \ Bubble_i + \sum_i a_i \ Tadpole_i + (R_1) + R_2 $$

where Box, ..., Tadpole refer to the one-loop Feynman integrals with 4, ..., 1 external leg, ($R_1$ is the rational part originating from the reduction process of a 4–dimensional numerator in the OPP method\(^3\)) and $R_2$ is the rational part originating by the explicit dependence of the numerator on the $\varepsilon$-dimension and can be reproduced by tree-like Feynman rules involving up to 4 particles\(^4\).

\(^4\)G. Ossola, C. G. Papadopoulos and R. Pittau, JHEP 05 (2008), 004
In HELAC-1LOOP\textsuperscript{5} the OPP method (\textit{integrand level}) is used for the amplitude reduction. The main idea is that for any numerator its 4—dimensional part can be written as

\[
\tilde{N}(\tilde{k}) = \sum_{i_0<i_1<i_2<i_3}^{l} \left[ d(i_0, i_1, i_2, i_3) + \tilde{d}(\bar{k}, i_0, i_1, i_2, i_3) \right] \prod_{i \neq i_0, i_1, i_2, i_3}^{l} \tilde{D}_i
\]

\[
+ \sum_{i_0<i_1<i_2}^{l} \left[ c(i_0, i_1, i_2) + \tilde{c}(\bar{k}, i_0, i_1, i_2) \right] \prod_{i \neq i_0, i_1, i_2}^{l} \tilde{D}_i
\]

\[
+ \sum_{i_0<i_1}^{l} \left[ b(i_0, i_1) + \tilde{b}(\bar{k}, i_0, i_1) \right] \prod_{i \neq i_0, i_1}^{l} \tilde{D}_i
\]

\[
+ \sum_{i_0}^{l} \left[ a(i_0) + \tilde{a}(\bar{k}, i_0) \right] \prod_{i \neq i_0}^{l} \tilde{D}_i
\]

where \(d_i = d(i_0, i_1, i_2, i_3)\), \(c_i = c(i_0, i_1, i_2)\), \(b_i = b(i_0, i_1)\), \(a_i = a(i_0)\), and \(\tilde{d}, \tilde{c}, \tilde{b}, \tilde{a}\) integrate to zero (spurious terms). The coefficients are determined by solving (iteratively) systems of equations by evaluating \(\tilde{N}(\tilde{k})\) for values of \(\tilde{k}\), that are solutions of

\[
\tilde{D}_i(\tilde{k}) = 0, \text{ for } i = 0, \ldots, M - 1, \text{ and } M = 1, \ldots, 4.
\]

\textsuperscript{5}G. Bevilacqua, M. Czakon, M. V. Garzelli, A. van Hameren, A. Kardos, C. G. Papadopoulos, R. Pittau and M. Worek, Comput. Phys. Commun. \textbf{184} (2013), 986-997
The 4—*dimensional* numerator is numerically calculated by HELAC\textsuperscript{6}, which efficiently calculates tree-level amplitudes checking for all possible flavor, spin and color configurations using SM couplings and the color-connection representation!

In this set-up, a binary representation is used for the external particles ($l_{v_1}$ blobs) and a generation of all topologically inequivalent partitions of $n, n - 1, n - 2, \ldots, 1$ blobs attached to the loop is done. For example, for $n = 6$ we could have

![Diagram of tree-level amplitudes](image)

The blobs could contain propagators but they do not depend on $\bar{k}$. Each numerator contribution is calculated (by HELAC) by cutting the propagator-line connecting the first and the last blob and calculating the resulted $n + 2$ tree-level amplitude without using denominators for the internal loop propagators

**HELAC-1L00P:** Completely automated framework for the calculation of 1—loop amplitudes for $n$—particle processes!!!

**HELAC-2LOOP on the making**

Our intention for the construction of HELAC-2LOOP is to reuse as much as more from the already working framework of HELAC-1LOOP combined with new concepts for the amplitude reduction at 2-loops!

As in the 1-loop case, at 2-loops we expect that at $d \to 4$ for the Amplitude will hold true the following expression at the integrand level

$$A \equiv \sum_{I \subseteq T} \frac{N_I(k_1, k_2, p_1, \ldots, p_n, \gamma^\mu, \epsilon^\mu)}{\prod \{i_1, i_2, i_3\} \in I} D_{i_1}(k_1) D_{i_2}(k_2) D_{i_3}(k_1, k_2) = \sum_i c_i(s) F_i + \sum_j \tilde{c}_j(s) S_j + R_1 + R_2$$

where $T$ is the set containing the 2-loop graph topologies of the corresponding process, $F_i$ are the *master integrands* that will integrate to *master integrals*, $S_j$ are the *spurious* terms that will integrate to zero, and $\{R_1, R_2\}$ are the 2-loop generalization of the 1-loop rational terms$^7$.

Although some results are obtained using an *master integrand* + surface (spurious) terms approach in $d$-dimensions, a complete basis is still missing (case-by-case study).

In order to calculate the numerator a generation of the 2-loop amplitude graphs is needed in the "blob"-binary representation that is used internally by HELAC. For this purpose we have created two generators for obtaining two-loop graph topologies for massless particles running within the loop (no tadpole graphs) in a five list format.

---

$^7$The 2-loop $R_2$ terms have been computed in J. N. Lang, S. Pozzorini, H. Zhang and M. F. Zoller, JHEP **10** (2020), 016 and S. Pozzorini, H. Zhang and M. F. Zoller, JHEP **05** (2020), 077.
There exist three graph topologies for 2-loop amplitudes, for which we choose the following list parametrization

1) \textit{Theta—topologies}:

\begin{equation}
\equiv \{\{k_1\}, \{k_2\}, \{k_3\}, \{A\}, \{B\}\}
\end{equation}

2) \textit{Infinity—topologies}:

\begin{equation}
\equiv \{\{k_1\}, \{k_2\}\}
\end{equation}

3) \textit{Dumbbell—topologies}:

\begin{equation}
\equiv \{\{k_1\}, \{k_2\}, \{C\}, \{A\}, \{B\}\}
\end{equation}
In Theta—topologies the particles in the sublists \( \{k_1\}, \{k_2\} \) and \( \{k_3\} \) are counted starting from the point \( B \) and ending at \( A \). For Example:

\[
\equiv \{\{2, 1\}, \{64, 32\}, \{16\}, \{4\}, \{8\}\}
\]

In Infinity—topologies the particles in the sublists \( \{k_1\} \) and \( \{k_2\} \) are counted using a bottom-up approach.

In Dumbbell—topologies the particles in the sublists \( \{k_1\} \) and \( \{k_2\} \) are counted using a bottom-up approach, and the particles in the \( \{C\} \) sublist are counted starting from the point \( B \) and ending at \( A \).

\[
\equiv \{\{4, 2, 1\}, \{64, 32\}, \{8, 16\}, \{256\}, \{128\}\}
\]
Progress on 2-Loop Amplitude Reduction

We have created two generators, one implemented in Mathematica (BlobMod) and one implemented in Fortran (GENTOOLS), using two different approaches in the generation:

- **BlobMod** starts by creating all the possible sets of putting the external particles in the sublists. Then in order to create the sub-topologies\(^8\) if there exist lists with \(\text{Length[sublist] } \geq 2\) takes for every list all the possible combinations of summing at most 2 neighboring elements of the same sublist\(^9\). After the generation of all the topologies, graph-symmetries are applied in order to remove identical lists.

- **GENTOOLS** generates the topologies exactly in the opposite way! Starts by taking all the possible sets of putting the higher level blobs in the sublists (lower-topologies) and creates the higher topologies by taking all the possible splittings of the blobs. In order to remove the identical lists graph-symmetries are applied also in this case.

Perfect agreement found between the results of the two generators and q-graf (P. Nogueira, *J. Comput. Phys. 105* (1993)). For \(n \geq 6\) GENTOOLS is a lot faster from BlobMod!!!

\(^8\) Meaning topologies where more than one particles shrink into a vertex, \(lvl_2, \ldots, lvl_n\) blobs.

\(^9\) The elements of \(\{A\}\) and \(\{B\}\) are always summed from the beginning.
Graph symmetries

The graphs are symmetric on (combined or individual) mirror transformations on the vertical and the horizontal axis (swap of the three loop lines). For example

All the symmetries of the graphs can be expressed in symmetries of the lists using one or both of the following 2 actions:

- **Swap**: corresponds to the swap of two sublists. E.g. \(\{k_1\}, \{k_2\} \rightarrow \{k_2\}, \{k_1\}\).
- **Reversion**: corresponds to the reversion of the elements of a sublist. E.g. \(\{1, 2, 4\} \rightarrow \{4, 2, 1\}\).

See back-up slides for a collection of the list-symmetries of the 3 graph topologies.
Conclusion

• In order to apply an OPP-like Amplitude reduction, at the moment we are working on the upgrade of HELAC code such that to be able to numerically compute the 4–dimensional part of the numerator from the tree-level $n + 4$ amplitude.

• Next step: creation of a general \{master integrand + spurious terms\} basis, and calculation of the 2–loop $R_1$ rational terms.

• As already mentioned, hopefully some results are now available for crosschecks!

• In addition, we have also made progress on the second line of the Dyson-Schwinger equations

\[
\begin{align*}
\text{and using an Mathematica file, we are able to construct the integrand of the 2–loop Amplitude in $d$–dimensions!}
\end{align*}
\]
Thank you!

This research work was supported by the HFRI (Hellenic Foundation for Research and Innovation) under the HFRI PhD Fellowship grant (Fellowship Number: 554).
**Color connection representation**

- In the color connection representation, the gluons are represented by a pair of color/anti-color indices \((i, j)\) and the quarks (anti-quarks) by a single color \((i, 0)\) (anti-color \((0, j)\)) index, with \(i, j \in (1, \ldots, N_C)\). All the other particles that do not carry color have \((0, 0)\).

- The amplitude takes the following form

\[
M_{i_1, i_2, \ldots, i_k}^{j_1, j_2, \ldots, j_k} = \sum_{\sigma} \delta_{i_{\sigma_1}, j_1} \delta_{i_{\sigma_2}, j_2} \ldots \delta_{i_{\sigma_k}, j_k} A_{\sigma}
\]

with \(k = n_g + n_q\) and the sum is running over all the permutations (equal to \(k!\)). The color-stripped amplitudes, \(A_{\sigma}\), are calculated using properly defined Feynman rules [A. Cafarella, C. G. Papadopoulos and M. Worek, Comput. Phys. Commun. 180 (2009), 1941-1955].

- The total color factor is a product of \(\delta\)'s, and thus the color summed squared amplitude takes the form

\[
\sum_{\{i\},\{j\}} |M_{j_1, j_2, \ldots, j_k}^{i_1, i_2, \ldots, i_k}|^2 = \sum_{\sigma, \sigma'} A_{\sigma}^* C_{\sigma', \sigma} A_{\sigma}
\]

where the color matrix \(C_{\sigma', \sigma}\) is given by

\[
C_{\sigma', \sigma} = \sum_{\{i\},\{j\}} \delta_{i_{\sigma_1}, j_1} \delta_{i_{\sigma_2}, j_2} \ldots \delta_{i_{\sigma_k}, j_k} \delta_{i_{\sigma_1}, j_1} \delta_{i_{\sigma_2}, j_2} \ldots \delta_{i_{\sigma_k}, j_k} = N_{m}^{C(\sigma', \sigma)}
\]

with \(m(\sigma', \sigma)\) counting the number of common cycles of the 2 permutations.
**Theta—Topology symmetries**

The symmetries of the graphs are translated to the following symmetries for the lists of the Theta—Topologies\(^\text{10}\)

\[
\{\{k_1\}, \{k_2\}, \{k_3\}, \{A\}, \{B\}\} = \{R[\{k_1\}], R[\{k_2\}], R[\{k_3\}], \{B\}, \{A\}\} \\
= \{R[\{k_1\}], R[\{k_3\}], R[\{k_2\}], \{B\}, \{A\}\} \\
= \{R[\{k_2\}], R[\{k_1\}], R[\{k_3\}], \{B\}, \{A\}\} \\
= \{R[\{k_2\}], R[\{k_3\}], R[\{k_1\}], \{B\}, \{A\}\} \\
= \{R[\{k_3\}], R[\{k_1\}], R[\{k_2\}], \{B\}, \{A\}\} \\
= \{R[\{k_3\}], R[\{k_2\}], R[\{k_1\}], \{B\}, \{A\}\} \\
= \{\{k_1\}, \{k_3\}, \{k_2\}, \{A\}, \{B\}\} \\
= \{\{k_2\}, \{k_1\}, \{k_3\}, \{A\}, \{B\}\} \\
= \{\{k_2\}, \{k_3\}, \{k_1\}, \{A\}, \{B\}\} \\
= \{\{k_3\}, \{k_1\}, \{k_2\}, \{A\}, \{B\}\} \\
= \{\{k_3\}, \{k_2\}, \{k_1\}, \{A\}, \{B\}\}
\]

\(^{10}\)We use the notation \(R[\{k_i\}] := \text{Reverse}[\{k_i\}]\).
Infinity—Topology and Dumbbell—Topology symmetries

The symmetries of the graphs are translated to the following symmetries for the lists of the Infinity—Topologies:

\[
\{\{k_1\}, \{k_2\}\} = \{\{k_2\}, \{k_1\}\} \\
= \{R[\{k_1\}], \{k_2\}\} = \{\{k_1\}, R[\{k_2\}]\} = \{R[\{k_1\}], R[\{k_2\}]\} \\
= \{R[\{k_2\}], \{k_1\}\} = \{\{k_2\}, R[\{k_1\}]\} = \{R[\{k_2\}], R[\{k_1\}]\}
\]

The symmetries of the graphs are translated to the following symmetries for the lists of the Dumbbell—Topologies:

\[
\{\{k_1\}, \{k_2\}, \{C\}, \{A\}, \{B\}\} = \{R[\{k_1\}], \{k_2\}, \{C\}, \{A\}, \{B\}\} \\
= \{\{k_1\}, R[\{k_2\}], \{C\}, \{A\}, \{B\}\} \\
= \{R[\{k_1\}], R[\{k_2\}], \{C\}, \{A\}, \{B\}\} \\
= \{\{k_2\}, \{k_1\}, R[\{C\}], \{B\}, \{A\}\} \\
= \{R[\{k_2\}], \{k_1\}, R[\{C\}], \{B\}, \{A\}\} \\
= \{\{k_2\}, R[\{k_1\}], R[\{C\}], \{B\}, \{A\}\} \\
= \{R[\{k_2\}], R[\{k_1\}], R[\{C\}], \{B\}, \{A\}\}
\]
