SU(2) symmetry in a Hubbard model with spin-orbit coupling

X. Z. Zhang, L. Jin, and Z. Song

School of Physics, Nankai University, Tianjin 300071, China

We study the underlying symmetry in a spin-orbit coupled tight-binding model with Hubbard interaction. It is shown that, in the absence of the on-site interaction, the system possesses the SU(2) symmetry arising from the time reversal symmetry. The influence of the on-site interaction on the symmetry depends on the topology of the networks: The SU(2) symmetry is shown to be the spin rotation symmetry of a simply-connected lattice, so it still holds in the presence of the Hubbard correlation. In contrary, the on-site interaction breaks the SU(2) symmetry of a multi-connected lattice.

I. INTRODUCTION

The spin-orbit coupling effect as an important mechanism to control spin dynamics without introducing an external magnetic field [1], has received much attention in the context of spintronics and the attempts to build a spin-transistor since the first proposal by Datta and Das in 1990 [2]. Two widely discussed spin-orbit coupling contributions are the Rashba and the Dresselhaus effects [3-5]. Among many interesting questions the most important one concerns the underlying symmetry of this model, which reveals many far-reaching physical implications that are not obvious at the first glance. A paradigm example is the SU(2) symmetry discovered by Bernevig et al. in a class of spin-orbit coupled models including the model with equal Rashba and Dresselhaus coupling constants and the Dresselhaus [10] model. This finding predicted that a spin precession phenomena should be experimentally observable [6]. Most of the previous investigations have been focused on non-interacting systems, while less attention has been paid to the existence of the electron correlations arising from the Coulomb interaction.

In this article, we study the underlying symmetry in a spin-orbit coupled tight-binding model, to which only the time reversal symmetry is required. It is shown that, in the absence of the interaction between electrons, the system possesses the SU(2) symmetry arising from the time reversal symmetry. Remarkably, we find that the influence of the on-site interaction on the symmetry depends on the topology of the networks in the following way. This SU(2) symmetry is shown to be the spin rotation symmetry of a simply-connected lattice, so it still holds for the case of nonzero on-site interaction. In contrary, the on-site interaction breaks the SU(2) symmetry of a multi-connected lattice. Based on the exact solution of a ring system, our result is demonstrated explicitly.

The article is organized as follows: in Sec. II, we introduce a general spin-orbit coupled Hubbard Hamiltonian with the time reversal symmetry. In Sec. III, we first construct the SU(2) operators for an on-site interaction free system by using the Kramers degeneracy. In Sec. IV we investigate the influence of the on-site correlation to the SU(2) symmetry. Sec. V is the conclusion and a short discussion.

II. TIME REVERSAL SYMMETRY

The Hamiltonian $H$ is written as follows:

$$H = H_T + H_U,$$

$$H_T = \sum_{i \neq j} c_i^\dagger T_{ij} c_j + \text{H.c.} + \sum_i \mu_i c_i^\dagger c_i,$$

$$H_U = \sum_i U_i n_{i\uparrow} n_{i\downarrow},$$

where $c_i^\dagger$ and $c_i$ are the creation and annihilation fermion operators at the $i$th site that have two components,

$$c_i = \left( c_{i\uparrow}, c_{i\downarrow} \right),$$

$$c_i^\dagger = \left( c_{i\uparrow}^\dagger, c_{i\downarrow}^\dagger \right).$$

Here $H_T$ describes the motion of free particles, while $H_U$ represents the on-site interaction of opposite spin electrons. Unlike the simple Hubbard model, $T_{ij} / |T_{ij}|$ is no longer the unit matrix arising from the coupling between momentum (and/or position) operators and spin operators. In this work, we do not restrict the model to be in a certain explicit form, we only require it possessing the time reversal symmetry. Therefore the conclusion of this article is available to the Rashba and Dresselhaus types of spin-orbit interactions.

The time reversal operator for a spin-$\frac{1}{2}$ particles takes the form

$$\mathcal{T} = -i \sigma^y K,$$

where $K$ denotes the complex conjugation operator satisfying

$$K (c_{\text{-number}}) = (c_{\text{-number}})^* K.$$
and $\sigma^\alpha (\alpha = x, y, z)$ are the Pauli matrices. The Hubbard Hamiltonian $H$ possesses the time reversal symmetry if $K$ commutes with all the matrices $T_{ij}$, i.e., $[T, T_{ij}] = 0$ for arbitrary $\{i, j\}$. After a straightforward algebra, we can find that $T_{ij}$ should have the form

$$T_{ij} = t_{ij} \exp \left( i \frac{\theta_{ij} \vec{n}_{ij} \cdot \vec{\sigma}}{2} \right),$$

(5)

which can be determined by the specific model. Where $t_{ij}$ is a real number, $\theta_{ij}$ is an arbitrary angle and $\vec{n}_{ij}$ is a unit vector. Obviously, $T_{ij}/t_{ij}$ is a unitary matrix and represents the spin rotation operation.

As well known, the spin operators of the whole system are defined as

$$s^\alpha = \sum_{i=1}^{N} s_i^\alpha, \quad s_i^\alpha = \frac{1}{2} c_i^\dagger \sigma_\alpha c_i,$$

(6)

which obey the following commutation relations

$$[s^\alpha, s^\beta] = i \epsilon_{\alpha\beta\gamma} s^\gamma,$$

(7)

where $\epsilon_{\alpha\beta\gamma}$ is the Levi-Civita symbol.

At first, we concentrate on the case of the Hamiltonian of Eq. (1) without the spin-orbit interaction. In the absence of the spin-orbit interaction, $\theta_{ij} = 0$, we have

$$[\vec{s}, H_{\theta_{ij}=0}] = 0,$$

(8)

i.e., the system $H_{\theta_{ij}=0}$ possesses the SU(2) spin rotation symmetry. The conservation of $\vec{s}$ leads to the spin inversion symmetry along an arbitrary direction, which is in accordance with the result of the time reversal symmetry. According to the general analysis, the spin inversion symmetry is broken when the spin-orbit interaction is switched on. However, the time reversal symmetry still holds for nonzero $\theta_{ij}$. The objective of this article aims at the inverse problem, namely: Can the present system acquire a SU(2) symmetry from the time reversal symmetry? We will find that it is possible under certain conditions.

### III. ON-SITE INTERACTION FREE CASE

We start with the case of zero $U$, but nonzero $\theta_{ij}$. Due to the time reversal symmetry of the present system, the Hamiltonian can always be diagonalized in the form

$$H_T = \sum_{k, \lambda=1,2} \epsilon_k f_k^\dagger f_k + \sum_k \epsilon_k f_k^\dagger f_k,$$

(9)

where $\lambda = 1, 2$ labels the two fold degeneracy, $k$ labels the energy levels and the corresponding two component fermion operators

$$f_k^\dagger = \left( f_{k1}^\dagger, f_{k2}^\dagger \right), \quad f_k = \left( f_{k1}, f_{k2} \right).$$

(10)

The Kramers degeneracy allows us to construct the operators

$$F^\alpha = \sum_{k=1}^{N} f_k^\dagger \sigma_\alpha f_k,$$

(11)

which obey the SU(2) commutation relations

$$[F^\alpha, F^\beta] = i \epsilon_{\alpha\beta\gamma} F^\gamma.$$

(12)

In this sense, Eq. (9) describes a non-interacting Fermi gas of spin-1/2 particles. The two Kramers degenerate states can service as the two components of a pseudo spin. Obviously, we have

$$[\vec{F}, H_T] = 0,$$

(13)

which means that the system $H_T$ possesses a new type of SU(2) symmetry. Note that the construction of $\{F^\alpha\}$ is not unique, since any linear transformation of $\{f_{k1}, f_{k2}\}$ cannot change the the facts of Eqs. (12) and (13). In other words, $H_T$ is invariant under the local rotation of the pseudo spins $\{F^\alpha_k\}$.

An interesting question is that: Among all the sets of the conserved quantities $\{F^\alpha\}$, which one closes to the familiar physical quantity and is feasible to measure in experiment? It will be shown that the geometry and the spin-dependent interaction play an important role in this issue. It is also the main goal of the present article. To this end, we firstly investigate the Hamiltonian $H_T$ on a simply-connected network. It can be observed that, taking an arbitrary node as a start point there exists a unique path to another. A schematic illustration of the simply-connected network is presented in Fig. 1(a). This characteristic feature of such networks allows $H_T$ to be rewritten as

$$H_T = \sum_{i \neq j} t_{ij} d_i^\dagger d_j + H.c. + \sum_i \mu_i d_i^\dagger d_i,$$

(14)

by absorbing the unitary matrices in $T_{ij}$ into the fermion operators $d_i^\dagger$ and $d_j$. For instance, one can take the transformation

$$c_i^\dagger T_{ij} c_j = t_{ij} c_i^\dagger e^{i \theta_{ij} \vec{n}_{ij} \cdot \vec{\sigma}} c_j = t_{ij} d_i^\dagger d_j,$$

(15)

by the definition

$$d_i^\dagger = c_i^\dagger, \quad d_j = e^{i \theta_{ij} \vec{n}_{ij} \cdot \vec{\sigma}} c_j.$$

(16)

The equivalent Hamiltonian [14] represents a non-spin-orbit interaction system. Accordingly, one can construct the corresponding SU(2) operators

$$S^\alpha = \sum_{i=1}^{N} S_i^\alpha, \quad S_i^\alpha = \frac{1}{2} d_i^\dagger \sigma_\alpha d_i,$$

(17)
satisfying the following commutation
\[ [S^\alpha, S^\beta] = i\varepsilon_{\alpha\beta\gamma}S^\gamma. \] (18)

Similarly with Eq. (8), we have
\[ \left[ \vec{S}, H_T \right] = 0. \] (19)

The physics of \( \vec{S} \) can be understood by the following relationship between operators \( S_i^\alpha \) and \( s_i^\alpha \)
\[ S_i^\alpha = u_i s_i^\alpha u_i^\dagger, \] (20)
where \( u_i \) is a unitary matrix of the form \( e^{i\gamma_i} \).

From Eq. (23), we obtain the identity
\[ \sum_k d_k^\dagger d_k = \sum_j d_j^\dagger d_j, \] (25)
which leads to
\[ \vec{S} = \vec{f}. \] (26)

Then we can conclude that the SU(2) symmetry obtained from the time reversal symmetry of a simply-connected

system is essentially spin rotational symmetry. The conservative quantity \( \vec{f} \) is connected to an experimental observable \( \vec{S} \), which means a persistent spin helix. It is hardly observed in practice since a natural material with simply-connected geometry is rare. However, artificial lattices, such as arrays of quantum dots in semiconductor heterostructures or optical lattices—stable periodic arrays of potentials created by standing waves of laser light, can implement this task.

In contrary, for a multi-connected system illustrated in Fig. 1(b), the above analysis is invalid since one cannot find a set of unitary matrices \( \{u_i\} \) to implement the transformation of Eq. (21). Then for an on-site free system with the time reversal symmetry, it always possesses a SU(2) symmetry, but the physics of the symmetry depends on the underlying topology of the network.

**IV. ON-SITE INTERACTION EFFECT ON THE SYMMETRY**

In previous we have found that there is a SU(2) symmetry in a spin-orbit coupling system obeys the time reversal symmetry when the electron-electron interaction is absent. This indicates the macroscopic emergence of certain physical features (as ferromagnet, antiferromagnet, spin helix, etc.) in long time scale, especially in a multi-particle system. Nevertheless, the spin-dependent interaction between particles may break the symmetry. Now we turn to investigate the influence of the on-site interaction \( H_U \) to the SU(2) symmetry. Actually, applying the transformation \( d_i = u_i c_i \) to \( H_U \) on a simply-connected

FIG. 1: (Color online) Schematic illustration of (a) simply-connected network and (b) multi-connected network. If the connection between \( i \) and \( j \) is broken, the topology is changed from multi- to simply-connected one, which will affects the SU(2) symmetry of the system, especially in the presence of the on-site correlation.
system, we have
\[ H_U = \sum_i U_i c_i^\dagger c_i c_i^\dagger c_i = \sum_i U_i d_i^\dagger d_i d_i^\dagger d_i, \]
which means it is invariant under the transformation. Consequently for a simply-connected system, we still have
\[ [\hat{S}, H_U] = [\hat{S}, H] = 0. \]

This has many implications on a spin-orbit coupling system. Mathematically, it can be treated as a normal Hubbard model. Then all the conclusions for the Hubbard model on a simply-connected lattice are completely available for the present system. Here we only give a subtle conclusion from the Lieb theorem \[10\]. In the following, we present a statement for a Hubbard model with the spin-orbit interaction on a simply-connected network by simply modifying the abstract in Ref. \[10\]. In the attractive Hubbard Model (and some extended versions of it), the ground state is proved to have spin angular momentum \( S = 0 \) for every (even) electron filling. In the repulsive case, with a bipartite lattice and a half-filled band, the ground state has \( S = 1/2(|B| - |A|) \), where \(|B| \) (\(|A|\)) is the number of sites in the \( B \) (\( A \)) sublattice. In both cases the ground state is unique. We believe that such kind of rigorous result obtained from the simple present model, thereby providing a general guiding principle for spintronics.

Now we consider the case of a multi-connected system. Since the transformation \( d_i = u_i c_i \) term completely, we cannot judge the commutation relation \([\hat{T}, H] = [\hat{T}, H_U]\) in a general manner. However, a single example can provide the conclusion that the on-site interaction breaks the SU(2) symmetry generated by the operators \( \{ F^\alpha \} \), although the time reversal symmetry still holds.

We exemplify the above analysis by taking a simple multi-connected network, a ring system as an example. This may shed light on the role of the topology of the network. The Hamiltonian of the ring reads
\[ H_{\text{ring}} = H_{T}^{\text{ring}} + H_{U}^{\text{ring}}, \]
\[ H_{T}^{\text{ring}} = -J \sum_{j=1}^{N-1} c_j^\dagger c_{j+1} + J c_1^\dagger e^{-i\frac{\pi n}{N}} c_N + \text{H.c.}, \]
\[ H_{U}^{\text{ring}} = U \sum_{j=1}^{N} c_j^\dagger c_{j+1} c_{j+1}^\dagger c_j. \]

Here the spin-orbit interaction only exerts on the tunneling between sites 1 and \( N \). Despite its simplicity, it reveals the common properties of the underlying symmetry for more complex systems. It acts as a Möbius system.

\[ F^\alpha = \frac{1}{2} \sum_k \left( a_k^\dagger a_{2\pi - k - \pi/N} \right) \sigma_\alpha \left( a_k a_{2\pi - k - \pi/N} \right), \]
\[ k = n\pi/N, \quad n \in [0, N - 1], \]
and

\[ \mathcal{H}_{U}^{\text{ring}} = U \sum_{j=1}^{N} a_{j}^{\dagger} a_{j} a_{j+N}^{\dagger} a_{j+N}, \]  

respectively. After a lengthy but straightforward algebra, we have

\[ [I^{\alpha}, \mathcal{H}_{U}^{\text{ring}}] \neq 0. \]  

It is clear that the time reversal symmetry is not the sufficient condition for a SU(2) symmetry, since the validity of the symmetry depends on the geometry of the system as well as the on-site correlation. Only the coexistence of the closed loop in the network and the on-site interaction between particles can break the SU(2) symmetry.

V. CONCLUSION

In conclusion, we studied the underlying symmetry for a spin-orbit coupled tight-binding model with the time reversal symmetry. We found that the characteristics of the symmetry strongly depend on the topology of the network and the on-site interaction. It is shown that, in the case of zero on-site interaction, the system possesses the SU(2) symmetry arising from the Kramers degeneracy. The influence of the on-site interaction on the symmetry depends on the geometry of the networks: The SU(2) symmetry is shown to be the spin rotation symmetry of a simply-connected lattice, so it still holds for the case of nonzero \( U \). We also investigate the multi-connected system based on the exact solution of a simple ring. Our result showed that the on-site interaction can break the SU(2) symmetry of a multi-connected lattice.

Regarding the reason why the topology and on-site correlation affects the symmetry, it may do to its gauge characteristic. It has been pointed that one can regard the Rashba and the Dresselhaus spin-orbit interaction in two-dimensional semiconductor heterojunctions as a non-Abelian gauge field, or the Yang-Mills field \[^{12}\]. The Yang-Mills field generates a physical field due to which the wave function acquires a spin-dependent phase factor. Therefore it is not surprising that the topology of the system affects the symmetry.
