Growing Linear Consensus Networks Endowed by Spectral Systemic Performance Measures

Milad Siami† and Nader Motee*  

Abstract—We propose an axiomatic approach for design and performance analysis of noisy linear consensus networks by introducing a notion of systemic performance measure. This class of measures are spectral functions of Laplacian eigenvalues of the network that are monotone, convex, and orthogonally invariant with respect to the Laplacian matrix of the network. It is shown that several existing gold-standard and widely used performance measures in the literature belong to this new class of measures. We build upon this new notion and investigate a general form of combinatorial problem of growing a linear consensus network via minimizing a given systemic performance measure. Two efficient polynomial-time approximation algorithms are devised to tackle this network synthesis problem: a linearization-based method and a simple greedy algorithm based on rank-one updates. Several theoretical fundamental limits on the best achievable performance for the combinatorial problem is derived that assist us to evaluate optimality gaps of our proposed algorithms. A detailed complexity analysis confirms the effectiveness and viability of our algorithms to handle large-scale consensus networks.

I. INTRODUCTION

The interest in control systems society for performance and robustness analysis of large-scale dynamical network is rapidly growing [1]–[10]. Improving global performance as well as robustness to external disturbances in large-scale dynamical networks are crucial for sustainability, from engineering infrastructures to living cells; examples include a group of autonomous vehicles in a formation, distributed emergency response systems, interconnected transportation networks, energy and power networks, metabolic pathways and even financial networks. One of the fundamental problems in this area is to determine to what extent uncertain exogenous inputs can steer the trajectories of a dynamical network away from its working equilibrium point. To tackle this issue, the primary challenge is to introduce meaningful and viable performance and robustness measures that can capture essential characteristics of the network. A proper measure should be able to encapsulate transient, steady-state, macroscopic, and microscopic features of the perturbed large-scale dynamical network.

In this paper, we propose a new methodology to classify several proper performance measures for a class of linear consensus networks subject to external stochastic disturbances. We take an axiomatic approach to quantify essential functional properties of a number of sensible measures by introducing the class of systemic performance measures and show that this class of measures should satisfy monotonicity, convexity, and orthogonal invariance properties. It is shown that several existing and widely used performance measures in the literature are in fact special cases of this class of systemic measures [4], [6], [11]–[13].

The performance analysis of linear consensus networks subject to external stochastic disturbances has been studied in [1], [2], [12]–[16], where the $H_2$-norm of the network was employed as a scalar performance measure. In [1], the authors interpret the $H_2$-norm of the system as a macroscopic performance measure capturing the notion of coherence. It has been shown that if the Laplacian matrix of the coupling graph of the network is normal, the $H_2$-norm is a function of the eigenvalues of the Laplacian matrix [1], [12], [15]. In [2], the authors consider general linear dynamical networks and show that tight lower, and upper bounds can be obtained for the $H_2$-norm of the network from the exogenous disturbance input to a performance output, which are functions of the eigenvalues of the state matrix of the network. Besides the commonly used $H_2$-norm, there are several other performance measures that have been proposed in [1], [6], [17]. In [11], a partial ordering on linear consensus networks is introduced where it shows that several previously used performance measures are indeed Schur-convex functions in terms of the Laplacian eigenvalues. In a more relevant work, the authors of [18] show that performance measures that are defined based on some system norms, spectral, and entropy functions exhibit several useful functional properties that allow us to utilize them in network synthesis problems.

The first main contribution of this paper is introduction of a class of systemic performance measures that are spectral functions of Laplacian eigenvalues of the coupling graph of a linear consensus network. Several gold-standard and widely used performance measures belong to this class, for example, to name only a few, spectral zeta function, Gamma entropy, expected transient output covariance, system Hankel norm, convergence rate to consensus state, logarithm of uncertainty volume of the output, Hardy-Schatten system norm or $H_p$-norm, and many more. All these performance measures are monotone, convex, and orthogonally invariant. Our main goal is to investigate a canonical network synthesis problem: growing a linear consensus network by adding new interconnection links to the coupling graph of the network and minimizing a given systemic performance measure. In the context of graph theory, it is known that a simpler version of this combinatorial problem, when the cost function is the inverse of algebraic connectivity, is indeed NP-hard [19]. There have been some prior attempts to tackle this problem for some specific choices of cost functions (i.e., total effective resistance and the inverse of algebraic connectivity) based on semidefinite programing (SDP) relaxation methods [20], [21]. There is a similar version of this problem that is reported in [22], where the author studies convergence rate of circulant consensus networks by adding some long-range links. Moreover, a continuous (non-combinatorial) and relaxed version of our problem of interest has some connections to the sparse consensus network design problem [23]–[25], where they consider $\ell_1$-regularized $H_2$-optimal control problems. The other related works [26], [27] argue that some metrics based on controllability and observability Gramians are modular or submodular set functions, which they aim to show that their proposed simple greedy heuristic algorithms have guarantees sub-optimality bounds.

In our second main contribution, we propose two efficient polynomial-time approximation algorithms to solve the above mentioned combinatorial network synthesis problem: a linearization-based method and a simple greedy algorithm based on rank-one updates. Our complexity analysis asserts that computational complexity of our proposed algorithms are reasonable and make them particularly suitable for synthesis of large-scale consensus networks. To calculate

sub-optimality of our proposed approximation algorithms, we quantify the best achievable performance bounds for the network synthesis problem in Section V. Our obtained fundamental limits are exceptionally useful as they only depend on the spectrum of the original network and they can be computed a priori. In Subsection VII-B, we classify a subclass of differentiable systemic performance measures that are indeed supermodular. For this subclass, we show that our proposed simple greedy algorithm can achieve a \((1 - 1/e)\)-approximation of the optimal solution of the combinatorial network synthesis problem. Our extensive simulation results confirm effectiveness of our proposed methods.

II. PRELIMINARIES AND DEFINITIONS

A. Mathematical Background

The set of real numbers is denoted by \(\mathbb{R}\), the set of non–negative by \(\mathbb{R}_+\), and the set of positive real numbers by \(\mathbb{R}_{++}\). The cardinality of set \(\mathcal{E}\) is shown by \(|\mathcal{E}|\). We assume that \(\mathbb{R}_n\), \(\mathbb{R}_n^+\), and \(J_n\) denote the \(n\times1\) vector of all ones, the \(n\times n\) identity matrix, and the \(n\times n\) matrix of all ones, respectively. For a vector \(v = [v_i] \in \mathbb{R}^n\), \(\text{diag}(v) \in \mathbb{R}^{n \times n}\) is the diagonal matrix with elements of \(v\) orderly sitting on its diagonal, and for \(A = [a_{ij}] \in \mathbb{R}^{n \times n}\), \(\text{diag}(A) \in \mathbb{R}^n\) is diagonal elements of square matrix \(A\). We denote the generalized matrix inequality with respect to the positive semidefinite cone \(\mathbb{S}_+^n\) by “\(\preceq\)”.

Throughout this paper, it is assumed that all graphs are finite, simple, undirected, and connected. A graph herein is defined by a triple \(G = (\mathcal{V}, \mathcal{E}, w)\), where \(\mathcal{V}\) is the set of nodes, \(\mathcal{E} \subseteq \{(i, j) \mid i, j \in \mathcal{V}, i \neq j\}\) is the set of links, and \(w : \mathcal{E} \rightarrow \mathbb{R}_{++}\) is the weight function. The adjacency matrix \(A = [a_{ij}]\) of graph \(G\) is defined in such a way that \(a_{ij} = w(e)\) if \(e = \{i, j\} \in \mathcal{E}\), and \(a_{ij} = 0\) otherwise. The Laplacian matrix of \(G\) is defined by \(L := \Delta - A\), where \(\Delta = \text{diag}(d_1, \ldots, d_n)\) and \(d_i\) is degree of node \(i\). We denote the set of Laplacian matrices of all connected weighted graphs with \(n\) nodes by \(\mathcal{L}_n\). Since \(G\) is undirected and connected, the Laplacian matrix \(L\) has \(n-1\) strictly positive eigenvalues and one zero eigenvalue. Assuming that \(0 = \lambda_1 < \lambda_2 \leq \ldots \leq \lambda_n\) are eigenvalues of Laplacian matrix \(L\), we define operator \(\Lambda : \mathbb{S}_+^n \rightarrow \mathbb{R}_{++}^{n \times n}\) by

\[
\Lambda(L) = \begin{bmatrix} \lambda_2 & \cdots & \lambda_n \end{bmatrix}^T.
\]

The Moore-Penrose pseudo-inverse of \(L\) is denoted by \(L^+ = [l_{ij}^+]\), which is a square, symmetric, doubly-centered and positive semi-definite matrix. For a given link \(e = \{i, j\}\), \(r_{e}(L)\) denotes the effective resistance between nodes \(i\) and \(j\) in a graph with the Laplacian matrix \(L\), where its value can be calculated as follows

\[
r_{e}(L) = l_{ii}^+ + l_{jj}^+ - 2l_{ij}^+, \tag{2}
\]

where \(L^+ = [l_{ij}^+]\). For every real \(q\), powers of pseudo inverse of \(L\) is represented by \(L^{+q} := (L^+)^q\).

Definition 1: The derivative of a scalar function \(\rho(.)\), with respect to the \(n\text{-by-}n\) matrix \(X\), is defined by

\[
\nabla \rho(X) := \begin{bmatrix} \frac{\partial \rho}{\partial x_{11}} & \frac{\partial \rho}{\partial x_{12}} & \cdots & \frac{\partial \rho}{\partial x_{1n}} \\ \frac{\partial \rho}{\partial x_{21}} & \frac{\partial \rho}{\partial x_{22}} & \cdots & \frac{\partial \rho}{\partial x_{2n}} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial \rho}{\partial x_{n1}} & \frac{\partial \rho}{\partial x_{n2}} & \cdots & \frac{\partial \rho}{\partial x_{nn}} \end{bmatrix},
\]

where \(X = [x_{ij}]\). The directional derivative of function \(\rho(X)\) in the direction of matrix \(Y\) is given by

\[
\nabla_Y \rho(X) = \langle \nabla \rho(X), Y \rangle = \text{Tr} \left( \nabla \rho(X) Y \right),
\]

where \(\langle .., .. \rangle\) denotes the inner product operator.

The following Majorization definition is from [28].

Definition 2: For every \(x \in \mathbb{R}^n_+\), let us define \(x^\dagger\) to be a vector whose elements are a permuted version of elements of \(x\) in descending order. We say that \(x\) majorizes \(y\), which is denoted by \(x \succeq y\), if and only if \(1^T x = 1^T y\) and \(\sum_{i=1}^{k} x_i^\dagger \geq \sum_{i=1}^{k} y_i^\dagger\) for all \(k = 1, \ldots, n - 1\).

The vector majorization is not a partial ordering. This is because from relations \(x \succeq y\) and \(y \succeq x\) one can only conclude that the entries of these two vectors are equal, but possibly with different orders. Therefore, relations \(x \succeq y\) and \(y \succeq x\) do not imply \(x = y\).

Definition 3 ([28]): The real-valued function \(F : \mathbb{R}^n_+ \rightarrow \mathbb{R}\) is called Schur–convex if \(F(x) \geq F(y)\) for every two vectors \(x\) and \(y\) with property \(x \succeq y\).

B. Noisy linear consensus networks

We consider the class of linear dynamical networks that consist of multiple agents with scalar state variables \(x_i\) and control inputs \(u_i\) whose dynamics evolve in time according to

\[
\dot{x}_i(t) = u_i(t) + \xi_i(t) \tag{3}
\]

\[
y_i(t) = x_i(t) - x_i(\bar{t}) \tag{4}
\]

for all \(i = 1, \ldots, n\), where \(x_i(0) = x_i^*\) is the initial condition and \(\bar{t}\) is the average of all states at time instant \(t\). The impact of the uncertain environment on each agent’s dynamics is modeled by the exogenous noise input \(\xi_i(t)\). By applying the following feedback control law to the agents of this network

\[
u_i(t) = \sum_{j=1}^{n} k_{ij} (x_j(t) - x_i(t)), \tag{5}
\]

the resulting closed-loop system will be a first-order linear consensus network. The closed-loop dynamics of network (3, 4) with feedback control law (5) can be written in the following compact form

\[
\dot{x}(t) = -L x(t) + \xi(t) \tag{6}
\]

\[
y(t) = M_n x(t), \tag{7}
\]

with initial condition \(x(0) = x^*\), where \(x = [x_1, \ldots, x_n]^T\) is the state, \(y = [y_1, y_2]^T\) is the output, and \(\xi = [\xi_1, \xi_2]^T\) is the exogenous noise input of the network. The state matrix of the network is a graph Laplacian matrix that is defined by \(L = [l_{ij}]\), where

\[
l_{ij} := \begin{cases} -k_{ij} & \text{if } i \neq j \\ k_{ii} + \ldots + k_{in} & \text{if } i = j \end{cases} \tag{8}
\]

and the output matrix is a centering matrix that is defined by

\[
M_n := I_n - \frac{1}{n} J_n. \tag{9}
\]

The underlying coupling graph of the consensus network (9–11) is a graph \(G = (\mathcal{V}, \mathcal{E}, w)\) with node set \(\mathcal{V} = \{1, \ldots, n\}\), edge set

\[
\mathcal{E} = \{\{i, j\} \mid \forall i, j \in \mathcal{V}, k_{ij} \neq 0\}, \tag{10}
\]

and weight function

\[
w(e) = k_{ij}, \tag{11}
\]

for all \(e = \{i, j\} \in \mathcal{E}\), and \(w(e) = 0\) if \(e \notin \mathcal{E}\). The Laplacian matrix of graph \(G\) is equal to \(L\).

Assumption 1: All feedback gains (weights) satisfy the following properties for all \(i, j \in \mathcal{V}\):

(a) non-negativity: \(k_{ij} \geq 0\),

(b) symmetry: \(k_{ij} = k_{ji}\),

(c) simpleness: \(k_{ii} = 0\).
Property (b) implies that feedback gains are symmetric and (c) means that there is no self-feedback loop in the network.

Assumption 2: The coupling graph $G$ of the consensus network (6)-(7) is connected and time-invariant.

According to Assumption 1, the underlying coupling graph is undirected and simple. Assumption 2 implies that only one of the modes of network (6)-(7) is marginally stable with eigenvector $\mathbb{1}_n$, and all other ones are stable. The marginally stable mode, which corresponds to the only zero Laplacian eigenvalue of $L$, is unobservable from the output (7). The reason is that the output matrix of the network satisfies $M_n \mathbb{1}_n = 0$. When there is no exogenous noise input, i.e., $\xi(t) = 0$ for all time, state of all agents converge to a consensus state which the state of all agents are dispersed from the consensus state.

III. SYSTEMIC PERFORMANCE MEASURES

The notion of systemic performance measure refers to a real-valued operator over the set of all linear consensus networks governed by (6)-(7) with the purpose of quantifying the quality of noise propagation in these networks. We have adopted an axiomatic approach to introduce and categorize a class of such operators that are obtained through our close examination of functional properties of several existing gold standard measures of performance in the context of network engineering and science. In order to state our findings in a formal setting, we observe that every network with dynamics (6)-(7) is uniquely determined by its Laplacian matrix. Therefore, it is reasonable to define a systemic performance measure as an operator over the set of Laplacian matrices $\mathcal{L}_n$.

Definition 4: An operator $\rho : \mathcal{L}_n \to \mathbb{R}$ is called a systemic performance measure if it satisfies the following properties for all Laplacian matrices in $\mathcal{L}_n$:

1. Monotonicity: If $L_2 \preceq L_1$, then $\rho(L_1) \leq \rho(L_2)$;
2. Convexity: For all $0 \leq \alpha \leq 1$, $\rho(\alpha L_1 + (1 - \alpha)L_2) \leq \alpha \rho(L_1) + (1 - \alpha)\rho(L_2)$;
3. Orthogonal invariance: For all orthogonal matrices $U \in \mathbb{R}^{n \times n}$,
   \[ \rho(L) = \rho(U L U^T). \]

Property 1 guarantees that strengthening couplings in a consensus network never worsens the network performance with respect to a given systemic performance measure. The coupling strength among the agents can be enhanced by several means, for example, by adding new feedback interconnections and/or increasing weight of an individual feedback interconnection. The monotonicity property induces a partial ordering on all linear consensus networks governed by (6)-(7). Property 2 requires that a viable performance measure should be amenable to convex optimization algorithms for network synthesis purposes. Property 3 implies that a systemic performance measure depends only on the Laplacian eigenvalues.

Theorem 1: Every operator $\rho : \mathcal{L}_n \to \mathbb{R}$ that satisfies Properties 2 and 3 in Definition 4 is indeed a Schur-convex function of Laplacian eigenvalues, i.e., there exists a Schur-convex spectral function $\Phi : \mathbb{R}^{n-1} \to \mathbb{R}$ such that

\[ \rho(L) = \Phi(\lambda_2, \ldots, \lambda_n). \]

Proof: For every $L \in \mathcal{L}_n$, the value of the systemic performance measure can be written as a composition of two functions as follows

\[ \rho(L) = \Phi(\lambda_2, \ldots, \lambda_n). \]

When the network is fed with a nonzero exogenous noise input, the limit behavior is not expected anymore and the state of all agents will be fluctuating around the consensus state without converging to it. Before providing a formal statement of the problem of growing a linear consensus network, we need to introduce a new class of performance measures for networks (6)-(7) that can capture the effect of noise propagation throughout the network and quantify degrees to which the state of all agents are dispersed from the consensus state.

IV. GROWING A LINEAR CONSUSN NETWORK

The network synthesis problem of interest is to improve the systemic performance of network (6)-(7) by establishing (10)-(11) and a set of candidate feedback interconnection links is uniquely determined by its Laplacian matrix. Therefore, it is reasonable to define a systemic performance measure as an operator over the set of Laplacian matrices $\mathcal{L}_n$.

Definition 4: An operator $\rho : \mathcal{L}_n \to \mathbb{R}$ is called a systemic performance measure if it satisfies the following properties for all Laplacian matrices in $\mathcal{L}_n$:

1. Monotonicity: If $L_2 \preceq L_1$, then $\rho(L_1) \leq \rho(L_2)$;
2. Convexity: For all $0 \leq \alpha \leq 1$, $\rho(\alpha L_1 + (1 - \alpha)L_2) \leq \alpha \rho(L_1) + (1 - \alpha)\rho(L_2)$;
3. Orthogonal invariance: For all orthogonal matrices $U \in \mathbb{R}^{n \times n}$,
   \[ \rho(L) = \rho(U L U^T). \]

Property 1 guarantees that strengthening couplings in a consensus network never worsens the network performance with respect to a given systemic performance measure. The coupling strength among the agents can be enhanced by several means, for example, by adding new feedback interconnections and/or increasing weight of an individual feedback interconnection. The monotonicity property induces a partial ordering on all linear consensus networks governed by (6)-(7). Property 2 requires that a viable performance measure should be amenable to convex optimization algorithms for network synthesis purposes. Property 3 implies that a systemic performance measure depends only on the Laplacian eigenvalues.

Theorem 1: Every operator $\rho : \mathcal{L}_n \to \mathbb{R}$ that satisfies Properties 2 and 3 in Definition 4 is indeed a Schur-convex function of Laplacian eigenvalues, i.e., there exists a Schur-convex spectral function $\Phi : \mathbb{R}^{n-1} \to \mathbb{R}$ such that

\[ \rho(L) = \Phi(\lambda_2, \ldots, \lambda_n). \]

Proof: For every $L \in \mathcal{L}_n$, the value of the systemic performance measure can be written as a composition of two functions as follows

\[ \rho(L) = \Phi(\lambda_2, \ldots, \lambda_n). \]

When the network is fed with a nonzero exogenous noise input, the limit behavior is not expected anymore and the state of all agents will be fluctuating around the consensus state without converging to it. Before providing a formal statement of the problem of growing a linear consensus network, we need to introduce a new class of performance measures for networks (6)-(7) that can capture the effect of noise propagation throughout the network and quantify degrees to which the state of all agents are dispersed from the consensus state.

Theorem 1: Every operator $\rho : \mathcal{L}_n \to \mathbb{R}$ that satisfies Properties 2 and 3 in Definition 4 is indeed a Schur-convex function of Laplacian eigenvalues, i.e., there exists a Schur-convex spectral function $\Phi : \mathbb{R}^{n-1} \to \mathbb{R}$ such that

\[ \rho(L) = \Phi(\lambda_2, \ldots, \lambda_n). \]

Proof: For every $L \in \mathcal{L}_n$, the value of the systemic performance measure can be written as a composition of two functions as follows

\[ \rho(L) = \Phi(\lambda_2, \ldots, \lambda_n). \]

When the network is fed with a nonzero exogenous noise input, the limit behavior is not expected anymore and the state of all agents will be fluctuating around the consensus state without converging to it. Before providing a formal statement of the problem of growing a linear consensus network, we need to introduce a new class of performance measures for networks (6)-(7) that can capture the effect of noise propagation throughout the network and quantify degrees to which the state of all agents are dispersed from the consensus state.

Theorem 1: Every operator $\rho : \mathcal{L}_n \to \mathbb{R}$ that satisfies Properties 2 and 3 in Definition 4 is indeed a Schur-convex function of Laplacian eigenvalues, i.e., there exists a Schur-convex spectral function $\Phi : \mathbb{R}^{n-1} \to \mathbb{R}$ such that

where $\hat{L}$ is the Laplacian matrix of an appended candidate subgraph $\hat{G}$ and the resulting network with Laplacian matrix $L + \hat{L}$ is referred to as the augmented network. The role of the candidate set $\mathcal{E}_c$ is to pre-specify authorized locations to establish new feedback interconnections in the network.

The network synthesis problem (17) is inherently combinatorial and it is known that a simpler version of this problem with $\rho(L) = \lambda_2^{-1}$ is in fact NP-hard [19]. There have been some prior attempts to tackle problem (17) for some specific choices of performance measures, such as total effective resistance and the inverse of algebraic connectivity, based on convex relaxation methods [20], [21] and greedy methods [22]. In Sections VI and VII, we propose approximation algorithms to compute sub-optimal solutions for (17) with respect to the broad class of systemic performance measures. We propose an exact solution for (17) when $k = 1$ and two tractable and efficient approximation methods when $k > 1$ with computable performance bounds. Besides, in Section VII, we demonstrate that a subclass of systemic performance measures has a supermodularity property. This provides approximation guarantees for our proposed approximation algorithm.

### V. Fundamental Limits on the Best Achievable Performance Bounds

In the following, we present theoretical bounds for the best achievable values for the performance measure in (17). Let us denote the optimal cost value of the optimization problem (17) by $r_k^*(\varpi)$.

For a given systemic performance measure $\rho : \Sigma_n \to \mathbb{R}$, we recall that according to Theorem 1 there exists a spectral function $\Phi$ such that

$$\rho(L) = \Phi(\lambda_2, \ldots, \lambda_n).$$

**Theorem 2:** Suppose that a consensus network $G$ with an ordered set of Laplacian eigenvalues $\lambda_2 \leq \ldots \leq \lambda_n$, a set of candidate links $\mathcal{E}_c$, and design parameter $1 \leq k \leq n - 1$ are given. The following inequality

$$r_k^*(\varpi) > \Phi(\lambda_{k+2}, \ldots, \lambda_n, \infty, \ldots, \infty)$$

holds for all weight functions $\varpi$. For $k \geq n$, all lower bounds are equal to $\Phi(\infty, \ldots, \infty)$. Moreover, if the systemic performance measure has the following decomposable form

$$\rho(L) = \sum_{i=2}^{n} \varphi(\lambda_i),$$

where $\varphi : \mathbb{R} \to \mathbb{R}_+$ is a decreasing convex function and $\lim_{\lambda \to \infty} \varphi(\lambda) = 0$, then the best achievable performance measure is characterized by

$$r_k^*(\varpi) = \sum_{i=k+2}^{n} \varphi(\lambda_i).$$

**Proof:** For a given weight function $\varpi : \mathcal{E}_c \to \mathbb{R}_+$, we show that inequality (18) holds for every $\hat{E} \in \Pi_k(\mathcal{E}_c)$. Assume that $\hat{L}$ is the Laplacian of the graph formed by $k$ added edges. We note that $\text{rank}(\hat{L}) = k' \leq k$. Therefore $\text{dim}(\ker \hat{L}) = n - k' \geq n - k$. Therefore, we can define the nonempty set $M_j$ for $2 \leq j \leq n$, as follows

$$M_j = \text{span}\{u_1, \ldots, u_{j+k'}\} \cap \text{span}\{v_1, \ldots, v_n\} \cap \ker \hat{L},$$

where $u_i$’s and $v_i$’s are orthonormal eigenvectors of $L$ and $L + \hat{L}$, respectively. We now choose a unit vector $v \in M_j$. It then follows that:

$$\lambda_j(L + \hat{L}) \leq v^T(L + \hat{L})v = v^TLv \leq \lambda_{j+k'}(L).$$

Therefore, according to (20) and the monotonicity property of the systemic measure $\rho$, we get

$$\rho(L + \hat{L}) \geq \Phi(\lambda_{k+2}, \ldots, \lambda_n, \infty, \ldots, \infty),$$

for all $\hat{E} \in \Pi_k(\mathcal{E}_c)$. Inequality (18) now follows from (21) and this completes the proof. Note that inequality (19) is a direct consequence of (18) and $\lim_{\lambda \to \infty} \varphi(\lambda) = 0$.

**Theorem 3:** Suppose that in optimization problem (17), the set of candidate links form a complete graph, i.e., $|\mathcal{E}_c| = \frac{1}{2}m(n - 1)$. Then, there exists a weight function $\varpi_0 : \mathcal{E}_c \to \mathbb{R}_+$ and a choice of $k$ weighted links from $\mathcal{E}_c$ with weight function $\varpi : \mathcal{E}_c \to \mathbb{R}_+$ such that

$$r_k^*(\varpi) \leq \Phi(\lambda_{k+2}, \ldots, \lambda_n, \infty, \ldots, \infty)$$

holds for all weight functions $\varpi$ that satisfies $\varpi(e) \geq \varpi_0(e)$ for all $e \in \mathcal{E}_c$. Moreover, if the systemic performance measure has the following decomposable form

$$\rho(L) = \sum_{i=2}^{n} \varphi(\lambda_i),$$

where $\varphi : \mathbb{R} \to \mathbb{R}_+$ is a decreasing convex function and $\lim_{\lambda \to \infty} \varphi(\lambda) = 0$, then the best achievable performance measure is characterized by

$$r_k^*(\varpi) \leq \sum_{i=k+2}^{n} \varphi(\lambda_i).$$
Proof: We will show that there exists \( \hat{E} \in \Pi_k(E_c) \) for which (22) is satisfied. Without loss of generality, we may assume that \( k < n - 1 \). This is because otherwise, by adding \( n - 1 \) links, which forms a spanning tree, and increasing their weights the performance of the resulting network tends to \( \Phi(\infty, \cdots, \infty) \) (see Theorem 4). Let \( \hat{E} \subseteq E \) be the set of \( k \) links that do not form any cycle with \( \varepsilon_0(e) = \infty \) for all \( e \in \hat{E} \). Then, we know that
\[
\Lambda(L + \hat{L}) \geq \Lambda(L)
\]
and the \( k \) largest eigenvalues of \( L + \hat{L} \) are equal to \( \infty \). Using (23) and the monotonicity property of the systemic performance measure, we get
\[
\rho(L + \hat{L}) \leq \Phi(\lambda_2, \cdots, \lambda_{n-k}, \infty, \cdots, \infty).
\]
(25)

From \( r^*(\varepsilon) \leq \rho(L + \hat{L}) \) and using (25), we obtain (22). Note that inequality (23) is a direct consequence of (22) and \( \lim_{\lambda \to \infty} \varphi(\lambda) = 0 \).

Examples of systemic performance measures that satisfies condition of Theorem 2 include \( \zeta_q^t(L) \) for \( q \geq 1 \), \( I_x(L) \), and \( T_x(L) \).

Theorem 4: Let us consider a linear consensus network (6)-(7) that is endowed with systemic performance measure \( \rho : E_c \to \mathbb{R} \). Then, the network performance can be arbitrarily improved\(^\text{2}\) by adding only \( n - 1 \) links that form a spanning tree.

Proof: Let us denote the Laplacian matrix of the spanning tree by \( L_T \). In the following, we show that the performance of resulting network can be arbitrarily improved by increasing the weights of the spanning trees. Based on the monotonicity property, we have
\[
\rho(L + \kappa L_T) \leq \rho(\kappa L_T), \quad \kappa > 0, 
\]
(26)

Also, we know that \( \Lambda(\kappa L_T) = \kappa \Lambda(L_T) \). Therefore, using the fact that the spanning tree has only one zero eigenvalue, (13), we get
\[
\lim_{\kappa \to \infty} \rho(\kappa L_T) = \Phi(\infty, \cdots, \infty).
\]

Using this limit and (26) we get the desired result. \( \blacksquare \)

It should be emphasized that by increasing weights of all the edges, the network performance can be arbitrarily improved, i.e., the value of the systemic performance measure can be made arbitrarily close to \( \Phi(\infty, \cdots, \infty) \). Theorem 4 sheds more light on this fact by revealing the minimum number of required links and their graphical topology to achieve this goal.

The results of Theorems 2 and 3 can be effectively applied to select a suitable value for the design parameter \( k \) in optimization problem (17). Let us denote the value of the lower bound in (15) by \( \rho_k \). The performance of the original network is then \( \rho_0 = \rho(L) \). The percentage of performance enhancement can be computed by formula (27) for all values of parameter \( 1 \leq k \leq n - 1 \). For a given desired performance level, we can look up these numbers and find the minimum number of required links to be added to the network. This is explained in details in Example 5 and Figure 5 in Section VIII.

In next sections, we propose approximation algorithms to compute near-optimal solutions for the network synthesis problem (17).

VI. A LINEARIZATION-BASED APPROXIMATION METHOD

Our first approach is based on a linear approximation of the systemic performance measure when weights of the candidate links in \( E_c \) are small enough. In the next result, we calculate Taylor expansion of a systemic performance measure using notions of directional derivative for spectral functions.

\(^2\)This implies that the value of the systemic performance measure can be made close enough to \( \Phi(\infty, \cdots, \infty) \), the lower bound in inequality (18).

| Table II: Linearization-based algorithm |
|-----------------------------------------|
| **Algorithm**: Adding \( k \) links using linearization |
| **Input**: \( L, \varepsilon_c, \varepsilon, \) and \( k \) |
| 1: set \( L = 0 \) |
| 2: for \( i = 1 \) to \( k \) |
| 3: find \( e = (i, j) \in E_c \) that returns the maximum value for |
| 4: \( \varpi(e) (\varpi(L)_{ii} + \varpi(L)_{jj} - \varpi(L)_{ij} - \varpi(L)_{ji}) \) |
| 5: set the solution \( e^* \) |
| 6: update |
| 7: \( L = \hat{L} + \varpi(e^*)L_{e^*} \), and |
| 8: \( E_c = E_c \setminus \{ e^* \} \) |
| 9: end for |

**Lemma 1**: Suppose that a linear consensus network (6)-(7) is endowed with a differentiable systemic performance measure \( \rho \). Let us consider the cost function in optimization problem (17). If \( \hat{L} \) is the Laplacian matrix of an appended subgraph \( \hat{G} = (\mathcal{V}, \hat{E}, \varepsilon) \), then
\[
\nabla \rho(L) = W^T (\text{diag}(\varpi(L)) \varphi(\Lambda(L))) W
\]
holds for any matrix \( W \) that is defined by (15).

**Proof**: The expression (27) can be calculated using the spectral form of a given systemic performance measure described by (14) and according to (11) Corollary 5.2.7. Using the directional derivative of \( \rho \) along matrix \( L \), the Taylor expansion of \( \rho(L + \epsilon \hat{L}) \) is given by
\[
\nabla \rho(L) = \rho(L) + \epsilon \nabla \rho(L) \hat{L} + O(\epsilon^2),
\]
(28)

where \( \nabla \rho(L) \) is the directional derivative of \( \rho \) at \( L \) along matrix \( \hat{L} \). This implies that when weights of the candidate links are small enough, one can approximate the optimization problem (17) by the following optimization problem
\[
\min_{\hat{E} \in \Omega_k(E_c)} \text{Tr} \left( \nabla \rho(L) \hat{L} \right),
\]
(30)

where \( \hat{L} \) is the Laplacian matrix of an appended candidate subgraph \( \hat{G} = (\mathcal{V}, \hat{E}, \varepsilon) \). Therefore, the problem boils down to select the \( k \)-largest elements of the following set
\[
\{ \varpi(e) (\varpi(L)_{ii} + \varpi(L)_{jj} - \varpi(L)_{ij} - \varpi(L)_{ji}) | (i, j) \in E_c \}
\]

where \( \varpi(e) \) is weight of link \( e \). Table III presents our linearization approach as an algorithm. In some special cases, one can obtain an explicit closed-form formula for systemic performance measure of the resulting augmented network.

**Theorem 5**: Suppose that linear consensus network (6)-(7) with Laplacian matrix \( L \) is endowed with systemic performance measure (23) for \( q = 1 \). Let us consider optimization problem (17), where \( \hat{L} \) is the Laplacian matrix of a candidate subgraph \( \hat{G} = (\mathcal{V}, \hat{E}, \varepsilon) \). Then,
\[
\zeta_1(L + \epsilon \hat{L}) = \zeta_1(L) - \epsilon \sum_{e \in \hat{E}} \varpi(e) r_e(L^2) + O(\epsilon^2),
\]

where \( r_e(L^2) \) is the effective resistance between the two ends of \( e \) in a graph with node set \( V \) and Laplacian matrix \( L^2 \).

\[ (A + \epsilon X)^{-1} = A^{-1} - \epsilon A^{-1}XA^{-1} + O(\epsilon^2), \quad (31) \]

for given matrices \( A, X \in \mathbb{R}^{n \times n} \). Based on [2, Theorem 4], the performance measure \( \zeta_i(L) \) can be calculated by

\[ \zeta_i(L + \epsilon \tilde{L}) = \text{Tr}((L + \epsilon \tilde{L})^{-1}). \quad (32) \]

Moreover, according to the definition of the Moore-Penrose generalized matrix inverse, we have

\[ \left(L + \epsilon \tilde{L}\right)^{-1} = \left(L + \epsilon \tilde{L}\right)^{-1} - \frac{1}{n} J_n, \]

where \( \tilde{L} = L + \frac{1}{n} J_n \). Using (31) and (32), it follows that

\[ \left(L + \epsilon \tilde{L}\right)^{-1} = L^{-1} - \frac{1}{n} J_n - \epsilon L^{-1} \tilde{L}^{-1} + O(\epsilon^2). \quad (33) \]

Then we show that

\[ \text{Tr}(\tilde{L}^{-1} \tilde{L}^{-1}) = \text{Tr}(\tilde{L}^{-2}) = \sum_{e \in \mathcal{E}} \psi(e) r_e(L^2). \quad (34) \]

Using (32), (33) and (34), we get the desired result.

According to Theorem 5 when weights of the candidate links are small, in order to formulate the optimal cost value of (35), we need to define the notion of a companion operator for a given systemic performance measure. The problem of adding only one link can be formulated as follows

\[ \text{minimize } \sum_{e \in \mathcal{E}_c} \psi(e) r_e(L^2), \quad (35) \]

where \( \mathcal{E}_c \) is the Laplacian matrix of a candidate subgraph \( \mathcal{G}_c = (V, \{e, \tilde{e}\}) \). Let us denote the optimal cost of (35) by \( r^*_c(\psi) \). In order to formulate the optimal cost value of (35), we need to define the notion of a companion operator for a given systemic performance measure.

## VII. Greedy Approximation Algorithms

In this section, we propose an optimal algorithm to solve the network growing problem (17) when \( k = 1 \). It is shown that for some commonly used systemic performance measures, one can obtain a closed-form solution for \( k = 1 \). We exploit our results and propose a simple greedy approximation algorithm for (17) with \( k > 1 \) by adding candidate links one at a time. For some specific subclasses of systemic performance measures, we prove that our proposed greedy approximation algorithm enjoys guaranteed performance bounds with respect to the optimal solution of the combinatorial problem (17).

### A. Simple Greedy by Sequentially Adding Links

The problem of adding only one link can be formulated as follows

\[ \text{minimize } \sum_{e \in \mathcal{E}_c} \psi(e) r_e(L^2), \quad (35) \]

where \( \mathcal{E}_c \) is the Laplacian matrix of a candidate subgraph \( \mathcal{G}_c = (V, \{e, \tilde{e}\}) \). Let us denote the optimal cost of (35) by \( r^*_c(\psi) \). In order to formulate the optimal cost value of (35), we need to define the notion of a companion operator for a given systemic performance measure.

### TABLE III: Simple greedy algorithm

| Algorithm: Adding links Consecutively |
|--------------------------------------|
| Input: \( L, \mathcal{E}_c, \psi, \) and \( k \) |
| 1: set \( \tilde{L} = L \) |
| 2: for \( i = 1 \) to \( k \) |
| 3: find link \( e \in \mathcal{E}_c \) with maximum \( \rho(\tilde{L}) - \rho(\tilde{L} + \psi(e)L_e) \) |
| 4: set the solution \( e^* \) |
| 5: update |
| 6: \( \tilde{L} = \tilde{L} + \psi(e^*)L_{e^*} \) and |
| 7: \( \mathcal{E}_c = \mathcal{E}_c \setminus \{e^*\} \) |
| 8: end for |

**Lemma 2:** For a given systemic performance measure \( \rho : \mathcal{L}_n \to \mathbb{R} \), there exists a companion operator \( \psi : \mathcal{L}_n \to \mathbb{R} \) such that

\[ \rho(L) = \psi(L^2), \quad (36) \]

for all \( L \in \mathcal{L}_n \). Moreover, the companion operator of \( \rho \) is characterized by

\[ \psi(X) = \Phi(\mu_n^{-1}, \ldots, \mu_1^{-1}), \quad (37) \]

for all \( X \in \mathcal{L}_n \) with eigenvalues \( \mu_2 \leq \ldots \leq \mu_n \), where operator \( \Phi : \mathbb{R}^{n \times n} \to \mathbb{R} \) is defined by (13).

**Proof:** According to Theorem 1 there exists a Schur-convex spectral function \( \Phi : \mathbb{R}^{n \times n} \to \mathbb{R} \) such that

\[ \rho(L) = \Phi(\lambda_2, \ldots, \lambda_n). \]

In addition, we know that for the Moore-Penrose pseudo-inverse of matrix \( L \in \mathcal{L}_n \), we have the following

\[ \nu_i(L^2) = \lambda_{n-i+1}^{-1}(L) = \lambda_{n-i+1}, \]

for \( i = 2, \ldots, n \), and \( \lambda_1(L) = \lambda_1(L^2) = 0 \). Consequently, we can rewrite \( \rho(L) \) using its companion operator as

\[ \rho(L) = \Phi\left(\lambda_2(L), \ldots, \lambda_n(L)\right). \]

Therefore, by defining \( \psi : \mathcal{L}_n \to \mathbb{R} \) as (37), we get identity (36).

Table I shows some important examples of systemic performance measure and their corresponding companion operators.

**Theorem 6:** Suppose that a linear consensus network (56-57) endowed by a systemic performance measure \( \rho : \mathcal{L}_n \to \mathbb{R} \) is given. The optimal cost value of the optimization problem (35) is given by

\[ r^*_c(\psi) = \min_{e \in \mathcal{E}_c} \psi\left(L^2 - \frac{1}{\psi^{-1}(\psi) + r_e(L^2)} U_e\right), \quad (38) \]

where \( \psi \) is the corresponding companion operator of \( \rho \) and \( U_e \) for a link \( e = (i, j) \) is a rank-one matrix defined by

\[ U_e = (L_i - L_j)(L_i^T - L_j^T)^T, \quad (39) \]

in which \( L^2_i \) is the \( i \)-th column of matrix \( L^2 \).

**Proof:** We use the following matrix identity

\[ (L + L_e)^T = (L + E_e \psi(e)E_e^T)^{-1} - \frac{1}{n} J_n, \]

where \( E_e \) is the incidence matrix of graph \( \mathcal{G}_c \) and \( L = L + \frac{1}{n} J_n \). By utilizing the Woodbury matrix identity, we get

\[ (L + L_e)^T = L^T - L^{-1}E_e\left(\psi^{-1}(\psi) + E_e^T L^{-1} E_e\right)^{-1} E_e^T L^{-1}. \quad (40) \]

From the definition of the effective resistance between nodes \( i \) and \( j \), it follows that

\[ r_e(L) = E_e^T L^{-1} E_e = l_{ii}^e + l_{ij}^e - l_{ij}^e - l_{ji}^e. \]

**Proof:** We use the following matrix identity
On the other hand, we have
\[ L^{-1} E_e = \left( L - \frac{1}{n} J_n \right) E_e = L^1 E_e = L^1_i - L^0_i. \] (41)

Therefore, using (40) and (41), we have
\[ (L + E_e)^\dagger = L^\dagger - \frac{1}{w^{-1}(e) + r_e(L)}(L^1_i - L^0_i)^\dagger \]
\[ = L^\dagger - \frac{1}{w^{-1}(e) + r_e(L)} U_e. \] (42)

From (45) and (42), we can conclude the desired equation (38).

In some special cases, the optimal solution (38) can be computed very efficiently using a simple separable update rule.

**Theorem 7:** Suppose that linear consensus network \((G, L)\) with Laplacian matrix \(L\) is given. Then, for every link \(e \in E_e\) we have
\[ \zeta_1(L + E_e) = \zeta_1(L) - \frac{r_e(L^2)}{w^{-1}(e) + r_e(L)} \]
\[ \zeta_2^2(L + E_e) = \zeta_2^2(L) + \left( \frac{r_e(L^2)}{w^{-1}(e) + r_e(L)} \right)^2 - \frac{2 r_e(L^2)}{w^{-1}(e) + r_e(L)} \]
\[ v(L + E_e) = v(L) - \log \left( 1 + r_e(L) w(e) \right) \]
where \(r_e(L^m)\) is the effective resistance between the two ends of link \(e\) in a graph with node set \(V\) and Laplacian matrix \(L^m\) for \(m \in \{1, 2, 3\}\).

**Proof:** Based on Theorem 6 it is straightforward to get the desired result for \(\zeta_1(.)\) and \(\zeta_2(.)\). For the last part, using the definition of \(v(.)\) and (40), we get
\[ v(L + E_e) = \log \det \left( 2(L + E_e) + \frac{1}{n} J_n \right)^{-1} \]
\[ = \log \det \left( 2(L + E_e) + \frac{1}{n} J_n \right)^{-1}. \] (43)

According to the matrix determinant lemma we have
\[ \det(A + u^T u) = (1 + u^T A^{-1} u) \det(A). \] (44)

Now using (43) and (44), it follows that
\[ \det \left( 2(L + E_e) + \frac{1}{n} J_n \right)^{-1} = \det \left( (2L + \frac{1}{n} J_n)^{-1} - \frac{1}{2w^{-1}(e) + r_e(L)} L \right) \]
\[ = \left( 1 - \frac{r_e(L)}{w^{-1}(e) + r_e(L)} \right) \det \left( 2L + \frac{1}{n} J_n \right)^{-1}, \]
then by taking log from both sides, we get the desired result.

In these special cases, the computational complexity of calculating the optimal solution for network design problem (35) is relatively low. For \(q = 1\), the optimal cost value is equal to \(\zeta_1(L + L_e^c)\), where
\[ e^* = \arg \max_{e \in \bar{E}_c} \frac{r_e(L^2)}{w^{-1}(e) + r_e(L)} \]. (45)

and for \(q = 2\), the optimal cost value is equal to \(\zeta_2(L + L_e^c)\), where
\[ e^* = \arg \min_{e \in \bar{E}_c} \left( \frac{r_e(L^2)}{w^{-1}(e) + r_e(L)} \right)^2 - \frac{2 r_e(L^2)}{w^{-1}(e) + r_e(L)} \].

Moreover, for (50), the optimal cost value is equal to \(v(L + L_e^c)\), where
\[ e^* = \arg \min_{e \in \bar{E}_c} \log \left( 1 + r_e(L) w(e) \right) \].

The location of the optimal link is sensitive to its weight. For example when optimizing with respect to \(\zeta_1\), maximizers of \(r_e(L), r_e(L^2)\) and \(r_e(L^3)/r_e(L)\) can be three different links. In Example 3 and Fig. 1 of Section VIII we illustrate this point by means of a simulation.

Furthermore, one can obtain the following useful fundamental limits on the best achievable cost values.

**Theorem 8:** Let us denote the value of performance improvement by adding an edge \(e\) with an arbitrary positive weight to linear consensus network \((G, L)\) by
\[ \Delta \rho(L) = \rho(L) - \rho(L + E_e). \]

Then, the maximum achievable performance improvement is
\[ \Delta \rho(L) \leq \psi(L^1) - \psi(L^1 - r_e(L)^{-1} U_e) \], (46)

where \(U_e\) is given by (39) and the upper bound can be achieved as \(w\) tends to infinity. Moreover, we have the following explicit fundamental limits
\[ \Delta \zeta_1(L) \leq \frac{r_e(L^2)}{r_e(L)}, \]
\[ \Delta \zeta_2^2(L) \leq \left( \frac{r_e(L^2)}{r_e(L)} \right)^2 - 2 \frac{r_e(L^2)}{r_e(L)}. \] (48)

**Proof:** We utilize monotonicity property of companion operator of a systemic performance measure, i.e., \(L^1_i \leq L^2_i\), then
\[ \psi(L^1_i) \leq \psi(L^2_i), \]
and the inequality
\[ L^1 - r_e(L)^{-1} U_e \leq L^2 - \frac{1}{w^{-1} + r_e(L)} U_e \]
to show that
\[ \psi \left( L^1 - r_e(L)^{-1} U_e \right) \leq \psi \left( L^2 - \frac{1}{w^{-1} + r_e(L)} U_e \right). \]

From this inequality, we can directly conclude (46). For systemic performance measure \(\zeta_1(.)\), inequality (46) reduces to
\[ \Delta \zeta_1(L) \leq \mathcal{Tr}(L^1) - \mathcal{Tr} \left( L^1 - r_e(L)^{-1} U_e \right), \]
\[ = \mathcal{Tr}(r_e(L)^{-1} U_e) = r_e(L)^{-1} \mathcal{Tr}(U_e). \] (49)

Moreover, based on the definition of \(U_e\), we have
\[ \mathcal{Tr}(U_e) = \mathcal{Tr} \left( L^1 E_e^T E_e L^1 \right) = E_e L^1 E_e^T = r_e(L^2). \]
Using this and (49), it follows that
\[ \Delta \zeta_1(L) \leq \frac{r_e(L^2)}{r_e(L)}. \]

Similarly for \(\zeta_2(.)\), using (46) and the definition of \(\zeta_2(.)\), results in
\[ \Delta \zeta_2^2(L) \leq \mathcal{Tr} \left( L^1 - r_e(L)^{-1} U_e \right), \]
\[ = \frac{1}{r_e(L)} \mathcal{Tr} \left( U_e^2 \right) - 2 \mathcal{Tr} \left( r_e(L)^{-1} U_e L^1 \right) \]
\[ = \left[ \frac{r_e(L^2)}{r_e(L)} \right] - 2 \frac{\mathcal{Tr}(L^1 E_e^T E_e L^1)^2}{r_e(L)} \]
\[ = \left[ \frac{r_e(L^2)}{r_e(L)} \right] - 2 \frac{r_e(L^2)}{r_e(L)}. \] (50)

This completes proof.

The result of Theorem 8 asserts that, in general, performance improvement may not be arbitrarily large by adding only one new link. In some cases, however, performance improvement can be arbitrarily good. For instance, for the uncertainty volume of the
output, we have
\[
\lim_{w(e) \to +\infty} \Delta v(L) = +\infty .
\] (51)

The result of Theorem 6 can be utilized to devise a greedy approximation method by decomposing (17) into \( k \) successive tractable problems in the form of (35). In each iteration, Laplacian matrix of the next best candidate link as well as its location. Since the value of systemic performance measure can be calculated explicitly in each step using Theorem 6, one can explicitly calculate the value of systemic performance measure for the resulting augmented network. This value can be used to determine the effectiveness of this method. Table III summarizes all steps of our proposed greedy algorithm, where the output of the algorithm is the Laplacian matrix of the resulting augmented network. In Section VII, we present several supporting numerical examples.

Remark 1: The optimization problem (35) with performance measure \( \zeta_\gamma(L) = \lambda^{-1} \) was previously considered in [21], where a heuristic algorithm was proposed to compute an approximate solution. Later on, another approximate method for this problem was presented in [20]. Also, there is a similar version of this problem that is reported in [22], where the author studies convergence rate of circulant consensus networks by adding some long-range links. Moreover, a non-combinatorial and relaxed version of our problem of interest has some connections to the sparse consensus network design problem [23]–[25], where they consider \( \ell_1 \)-regularized \( \mathcal{H}_2 \) optimal control problems. When the candidate set \( \mathcal{E}_c \) is the set of all possible links except the network links, i.e., \( \mathcal{E}_c = \mathcal{V} \times \mathcal{V} \setminus \mathcal{E} \), and the performance measure is the logarithm of the uncertainty volume, our result reduces to the result reported in [26].

### B. Supermodularity and Guaranteed Performance Bounds

A systemic performance measure is a continuous function of link weights on the space of Laplacian matrices \( \mathcal{L}_n \). Moreover, we can represent a systemic performance measure equivalently as a set function over the set of weighted links. Let us denote by \( \Theta(\mathcal{V}) \) the set of all weighted graphs with a common node set \( \mathcal{V} \).

**Definition 5:** For a given systemic performance measure \( \rho : \mathcal{L}_n \to \mathbb{R} \), we associate a set function \( \tilde{\rho} : \Theta(\mathcal{V}) \to \mathbb{R} \) that is defined as
\[
\tilde{\rho}(\mathcal{G}) = \rho \left( \sum_{e \in \mathcal{E}} w(e) L_e \right) = \rho(L),
\]

Table IV: Some important examples of spectral systemic performance measures and their corresponding companion operators.

| Systemic Performance Measure | Symbol | Spectral Representation | The Corresponding Companion Operator |
|------------------------------|--------|------------------------|-------------------------------------|
| Spectral zeta function       | \( \zeta_\gamma(L) \) | \( \left( \sum_{i=2}^n \lambda_i^{-q} \right)^{1/q} \) | \( \sum_{i=2}^n \mu_i^{1/q} \) for \( q \geq 1 \) |
| Gamma entropy                | \( I_\gamma(L) \) | \( \gamma^2 \sum_{i=2}^n (\lambda_i - (\lambda_i^2 - \gamma^2)^{1/2}) \) | \( \gamma^2 \sum_{i=2}^n (\mu_i^{-1} - (\mu_i^2 - \gamma^2)^{1/2}) \) |
| Expected transient output covariance | \( \sigma(L) \) | \( \sum_{i=2}^n \lambda_i^{-1}(1 - e^{-\lambda_i t}) \) | \( \sum_{i=2}^n \mu_i(1 - e^{-\mu_i t}) \) |
| System Hankel norm           | \( \eta(L) \) | \( \sum_{i=2}^n \lambda_i^{-1} \) | \( \sum_{i=2}^n \mu_i \) |
| Uncertainty volume of the output | \( v(L) \) | \( (1 - n) \log 2 - \sum_{i=2}^n \log \lambda_i \) | \( (1 - n) \log 2 + \sum_{i=2}^n \log \mu_i \) |
| Hardy-Schatten system norm or \( \mathcal{H}_p \)-norm | \( \theta_p(L) \) | \( \left\{ \frac{1}{2\pi} \int_{-\infty}^{\infty} \sum_{k=1}^n \sigma_k(G(j\omega))p d\omega \right\}^{1/p} \) | \[ \alpha \left( \frac{\sum_{i=2}^n \mu_i^{1/p - 1}}{p} \right)^{1/p} \text{ for } 2 \leq p \leq \infty, \text{ where } \alpha_0^{-1} = \sqrt{-\beta(\frac{p}{2}, -\frac{1}{2})} \].

![Fig. 1: The interconnection topology of all three graphs, except for their highlighted blue links, are identical, which show the coupling graph of the linear consensus network in Example 6. The coupling graph shown in here is a generic connected graph with 50 nodes and 100 links, which are drawn by black lines. The optimal links are shown by blue line segments.](attachment:figure1.png)

| (a) | (b) | (c) |
corresponding set function \( \hat{\rho} : \Theta(\mathcal{V}) \to \mathbb{R} \), from Definition 5 is supermodular.

Proof: We know that
\[
d\frac{d}{dt}(L + t X) = \text{Tr}(\nabla \rho(L + t X)X),
\]
where \( t \in \mathbb{R}_+ \) and \( L, X \in \mathfrak{L}_n \). From (58), we get
\[
d\frac{d}{dt}(L_1 + t X) = \text{Tr}(\nabla \rho(L_1 + t X)X),
\]
where \( L_1, L_2 \in \mathfrak{L}_n \) and \( L_1 \preceq L_2 \). From the monotonicity property of \( \nabla \rho \) and (55), we get
\[
d\frac{d}{dt}(L_1 + t X) = \text{Tr}(\nabla \rho(L_1 + t X)X) \leq 0.
\]

Then, by taking integral from both sides of (55), and then using (50) we have
\[
\int_0^1 d\frac{d}{dt}(L_1 + t X)dt - \int_0^1 d\frac{d}{dt}(L_2 + t X)dt \leq 0,
\]
which directly implies that
\[
\rho(L_1 + X) - \rho(L_1) \leq \rho(L_2 + X) - \rho(L_2).
\]

On the other hand, the corresponding Laplacian matrices of \( G_1, G_2, G_1 \land G_2, \) and \( G_1 \lor G_2 \) are given as follows
\[
\begin{align*}
L_{G_1} &:= \sum_{e \in E} w_1(e)L_e, \\
L_{G_2} &:= \sum_{e \in E} w_2(e)L_e, \\
L_{G_1 \land G_2} &:= \sum_{e \in E} \min\{w_1(e), w_2(e)\}L_e, \\
L_{G_1 \lor G_2} &:= \sum_{e \in E} \max\{w_1(e), w_2(e)\}L_e.
\end{align*}
\]

Based on these definitions, we have
\[
L_{G_1 \lor G_2} \preceq L_{G_1}, L_{G_2} \preceq L_{G_1 \lor G_2}.
\]

By setting \( L_1 = L_{G_1 \land G_2}, L_2 = L_{G_1}, \) and \( X = L_{G_2} - L_{G_1 \lor G_2} \) in inequality (57), we get
\[
\rho(L_1, G_1, G_2) - \rho(L_1, G_1, G_2) = \rho(L_1, G_1) - \rho(L_1, G_1) \leq \rho(L_{G_1 \lor G_2}, G_1 \lor G_2) - \rho(L_{G_1 \lor G_2}).
\]

According to (55), we have
\[
L_{G_1 \lor G_2} = L_{G_1} + L_{G_2}.
\]

Therefore, based on equality (61), we can rewrite the right hand side of inequality (60), as follows
\[
\rho(L_{G_1 \lor G_2} + L_{G_2} - L_{G_1 \lor G_2}) = \rho(L_{G_1}) - \rho(L_{G_1 \lor G_2}).
\]

Finally, using Definition 5 and 60, we can conclude (55).

Example 1: In our first example, we show that the uncertainty volume of the output (60) satisfies conditions of Theorem 9. The gradient operator of this systemic performance measure is
\[
\nabla v(L) = -\left( L + \frac{1}{n} J_n \right)^{-1}.
\]

It is straightforward to verify that \( \nabla v(L) \) is monotone with respect to the cone of positive semidefinite matrices. Thus, \( v(L) \) is supermodular.

Example 2: In our second example, we consider a new class of systemic performance measures that are defined as
\[
m_q(L) = -\sum_{i=2}^n \lambda_i^q,
\]
where \( 0 \leq q \leq 1 \). According to Theorem 11 this spectral function is a systemic performance measure as function \( -\lambda^q \) for \( 0 \leq q \leq 1 \) is a decreasing convex function on \( \mathbb{R}_+ \). Moreover, its gradient operator, which is given by \( \nabla m_q(L) = qL^{q-1} \) is monotonically increasing for all \( 0 \leq q \leq 1 \). Therefore, according to Theorem 9 systemic performance measure (63) is supermodular over the set of all weighted graphs with a common node set.

Remark 2: For a given performance measure \( \rho \), there are several different ways to define an extended set function for \( \rho \). These set functions may have different properties. For instance, the extended set function of \( \rho \) is supermodular over principle sub-matrices (33), but it is not supermodular over the set of all weighted graphs with a common node set (see Definition 5).

For those systemic performance measures that satisfy conditions of Theorem 9 one can provide guaranteed performance bounds for our proposed greedy algorithm in Subsection VII-A. The following result is based a well-known result from [32, Chapter III, Section 3].

Theorem 10: Suppose that systemic performance measure \( \rho : \mathfrak{L}_n \to \mathbb{R} \) is differentiable and \( \nabla \rho : \mathfrak{L}_n \to \mathbb{R}^{n \times n} \) is monotonically increasing with respect to the cone of positive semidefinite matrices. Then, the greedy algorithm in Table 11, starts with \( \hat{E} \) as the empty set and at every step selects an element \( e \in E \), that minimizes the marginal cost \( \rho(L + L_e - L_e) - \rho(L + L_e) \), provides a set \( \hat{E} \) that achieves a \((1-1/e)\)-approximation of the optimal solution of the combinatorial network synthesis problem (17).

Since the class of supermodular systemic performance measures are monotone, the combinatorial network synthesis problem (17) is polynomial-time solvable with provable optimality bounds (32). Supermodularity is not a ubiquitous property for all systemic performance measures. Nevertheless, our simulation results in Section VIII assert that the proposed greedy algorithm in Table 11 is quite powerful and provides tight and near-optimal solutions for a broad range of systemic performance measures.

C. Computational Complexity Discussion

As we discussed earlier, the network synthesis problem (17) is in general NP-hard. However, this problem is solvable when \( k = 1 \) and the best link can be found by running an exhaustive search over all possible scenarios, i.e., by calculating the value of a performance measure for all possible \( p \) augmented networks, where \( p \) is the number of candidate links. The computational complexity of evaluating

4 This means that \( \rho(L_1 + L_2) - \rho(L_1) \geq 1 - \frac{1}{e} \), where \( L^* \) is the optimum solution and \( \hat{L} \) is the solution of the greedy algorithm, or equivalently: 
\[
\frac{\rho(L_1 + L_2) - \rho(L_1)}{\rho(L_1 + L_2) - \rho(L_1)} \leq \frac{e}{e-1}.
\]

where \( e \) is Euler’s number.
performance of a given linear consensus network depends on the specific choose of a systemic performance measure. Let us denote computational complexity of a given systemic performance measure \( \rho : \Sigma \rightarrow \mathbb{R} \) by \( \mathcal{O}(M(\rho(n))) \). In the simple greedy algorithm of Table II, the difference term

\[
\rho(L) - \rho(L + \bar{\tau}(c)L_c)
\]

is calculated and updated for each candidate link at each step, for the total of \( k(p - \frac{p}{n^2}) \) times. Thus, the total computational complexity of our simple greedy algorithm is \( \mathcal{O}(M(\rho(n))p - \frac{p}{n^2}) \) operations. This computational complexity is at most \( \mathcal{O}(M(\rho(n))^2n^2) \), where \( p = \binom{n}{2} \), when the candidate set contains all possible links. The complexity of the brute-force method is \( \mathcal{O}(M(\rho(n))^2) \). This can be at most \( \mathcal{O}(M(\rho(n))2^p/\sqrt{p}) \). Moreover, if \( k \leq \sqrt{p} \), then the computational complexity will be \( \mathcal{O}(M(\rho(n))p^k/k!) \).

In some occasions, we can take advantage of the rank-one updates in Theorems 6 and 7 where it is shown that a rank-one deviation in a matrix results in a rank-one change in its inverse matrix as well. This helps reduce the computational complexity of (64) to the order of \( \mathcal{O}(n^2) \) instead of \( \mathcal{O}(n^3) \) operations. As it is shown in (64), one can apply the rank-one update on the matrix of effective resistances. As a result, we can update the effective resistances of all links in order of \( \mathcal{O}(n^2) \). More specifically, the matrix of effective resistances is given by

\[
R(L^{(n)}) := \frac{1}{n} \left( \text{diag}(L^{(n)}) + \text{diag}(L^{(n)}) \frac{1}{n} - 2L^{(n)} \right),
\]

for \( m \in \{1, 2, 3\} \), where \( R(L^{(m)})_{ij} = r_i(L^{(m)}) \). The update rule (65) can be obtained by substituting the rank-one update of \((L + L_c)^m\) from (42) in (65) and the \( m \)-th power of the rank-one update can be calculated in \( \mathcal{O}(n^2) \) as it can be cast as only matrix-vector products. Using these facts and the result of Theorem 7, the computational cost of (64) for systemic performance measures \( \zeta_1, \zeta_2, \) and \( \nu \) can be significantly reduced; more specifically, the computational complexity of our algorithm reduces to

\[
\mathcal{O} \left( \frac{n^3}{\text{calculating } L^{(1,m)} \text{ at the beginning}} + \frac{n^2}{\text{rank-one update}} \times \frac{k}{\text{number of steps}} \right).
\]

For a generic systemic performance measure \( \rho : \Sigma \rightarrow \mathbb{R} \), according to Theorem 1 calculating its value requires knowledge of all Laplacian eigenvalues of the coupling graph. It is known that the eigenvalue problem for symmetric matrices requires \( \mathcal{O}(n^{2.376} \log n) \) operations \( 45 \). Suppose that calculating the value of spectral function \( \Phi : \mathbb{R}^{\alpha-1} \rightarrow \mathbb{R} \) in Theorem 1 needs \( \mathcal{O}(M(\Phi(n))) \) operations. Thus, the value of systemic performance measure \( \rho(L) \) in equation (13) can be obtained by substituting the rank-one update of (64)

\[
\mathcal{O} \left( n^{2.376} \log n + M(\Phi(n)) \left( p - \frac{p}{n^2} \right) k! \right).
\]

and similarly (64), can be calculated in \( \mathcal{O}(n^{2.376} \log n + M(\Phi(n))) \). Based on this analysis, we conclude that the complexity of the greedy algorithm in Table III is at most

\[
\mathcal{O} \left( n^{2.376} \log n + M(\Phi(n)) \left( p - \frac{p}{n^2} \right) k! \right).
\]

VIII. Numerical Simulations

In this section, we support our theoretical findings by means of some numerical examples.

Example 3: This example investigates sensitivity of location of an optimal link as a function of its weight. Let us consider a linear consensus network (6)-(7), whose coupling graph is shown in Fig. 1/1 endowed by systemic performance measure (74) with \( q = 1 \). The graph shown in Fig. 1/1 is a generic unweighted connected graph with \( n = 50 \) nodes and 100 links. We solve the network synthesis problem 45 for the candidate set with \( |E_c| = \frac{1}{2}n(n-1) \) that covers all possible locations in the graph. It is assumed that all candidate links have an identical weight \( \tau_0 \). We use our rank-one update method in Theorem 7 to study the effect of \( \tau_0 \) on location of the optimal link. In Fig. 1/1(c), we observe that by increasing \( \tau_0 \), the optimal location changes. When \( \tau_0 = 1 \), our calculations reveal that the optimal link in Fig. 1/1(a), shown by a blue line segment, maximizes \( \tau_c(L^2) \) among all possible candidate links in set \( E_c \). By increasing the value of our design parameter to \( \tau_0 = 1.2 \) in Fig. 1/1(b), we observe that the location of the optimal link moves. In our last scenario in Fig. 1/1(c), by setting \( \tau_0 = 1.6 \), the optimal link moves to a new location that maximizes \( \tau_c(L^2) / \tau_c(L) \) among all possible candidate links.

Example 4: The usefulness of our theoretical fundamental hard limits in Theorem 3 in conjunction with our results in Theorem 7 is illustrated in Fig. 3. Suppose that a linear consensus network (6)-(7) with a generic coupling graph with \( n = 60 \), as shown in Fig. 2(a), is given. Let us consider the network design problem 45 with systemic performance measure (74) for \( q = 1 \). The set of candidate links is the set of all possible links in the coupling graph, i.e., \( |E_c| = \frac{1}{2}n(n-1) \), where it is assumed that all candidate links have an identical weight \( \tau_0 = 20 \). Our goal is to compare optimality of our low-complexity update rule against brute-force search over all \( |E_c| = 1770 \) possible augmented graphs. The value of the systemic performance measure for each candidate graph is marked by blue star in Fig. 3. In this plot, the black circle highlights the value of performance measure for the network resulting from the rank-one search 45. The red dashed line in Fig. 3 shows the best achievable value for \( \zeta_1 \) according to Theorem 2. The value of this hard limit can be calculated merely using Laplacian eigenvalues of the original graph shown in Fig. 2(a). The location of the optimal link is shown in Fig. 2(b). One observes from Fig. 3 that our theoretical fundamental limit justifies near-optimality.

---

Footnote:

6. This corresponds to calculating the value of a performance measure for all \( \binom{n}{2} \) possible augmented networks.
network performance improves by 40%. In order to make our comparison possible, we consider a problem (17); however, it cannot be used for medium to large size methods. Our simulation results reveal that the greedy algorithm to produce near-optimal solutions with respect to this class of measures. As one expects, our greedy algorithm outperforms our linearization-based method. It is noteworthy that the time complexity of the linearization method is comparatively less than the greedy algorithm. The usefulness of the linearization-based method accentuates itself when weight of candidate links are small and/or \( k \) is large.

**IX. DISCUSSION AND CONCLUSION**

In the following, we provide explanations for some of the outstanding and remaining problems related to this paper.

**Convex Relaxation:** The constraints of the combinatorial problem (17) can be relaxed by allowing the link weights to vary continuously. The relaxed problem will be a spectral convex optimization problem (36). In some special cases, such as when the cost function is \( \zeta_1 \) or \( \zeta_2 \), the relaxed problem can be equivalently cast as a semidefinite programming problem (11), (13). However, for a generic systemic performance measure, we need to develop some low-complexity specialized optimization techniques to solve the corresponding spectral optimization problem, which is beyond the scope of this paper.

**Higher-Order Approximations:** In Subsection V, we employed the first-order approximation of a systemic performance measure. One can easily extend our algorithm by considering second-order approximations of a systemic performance measure in order to gain better optimality gaps.

**Non-spectral Systemic Performance Measures:** The class of spectral systemic performance measures can be extended to include non-spectral measures as well. This can be done by relaxing and replacing the orthogonal invariance property by permutation invariance property. The local deviation error is an example of a non-spectral systemic performance measure (18), (37). Our ongoing research involves a comprehensive treatment of this class of measures.
Theorem G.1 in [28, Sec. 9], we know that $\phi$ is a decreasing convex function. Then, the following spectral function

$$\rho(L) = \sum_{i=2}^{n} \phi(\lambda_i)$$

is a systemic performance measure. Moreover, if $\phi$ is also a homogeneous function of order $-\kappa$ with $\kappa > 1$, then the following spectral function

$$\rho(L) = \left( \sum_{i=2}^{n} \phi(\lambda_i) \right)^{\frac{1}{\kappa}}$$

is also a systemic performance measure.

Proof: First we show that measure (66) is monotone with respect to the positive definite cone. If we assume that $L_2 \preceq L_1$, then based on Theorem A.1 in [28, Sec. 20], it follows that

$$\lambda_i(L_2) \leq \lambda_i(L_1), \text{ for } i = 1, 2, \ldots, n.$$  \hspace{1cm} (68)

Thus, using (68) and the fact that $\phi(\cdot)$ is decreasing, we get the monotonicity property of measure (66). Also, it is not difficult to show that measure (66) satisfies Property 2. To do so, let $L_1$ and $L_2$ be two Laplacian matrices in $\mathcal{L}_n$. Recall that $\Lambda(L_i)$, $i = 1, 2$ is the vector of eigenvalues of $L_i$ in ascending order. According to Theorem G.1 in [28, Sec. 9], we know that

$$\Lambda(\alpha L_1 + (1 - \alpha) L_2) \preceq \alpha \Lambda(L_1) + (1 - \alpha) \Lambda(L_2),$$  \hspace{1cm} (69)

for every $0 \leq \alpha \leq 1$, and $\preceq$ denotes the majorization preorder [28]. Besides, we note that based on Proposition C.1 in [28, Sec. 3], measure (66) is a Schur-convex function. Consequently, using this property and (69), we have

$$\rho(\alpha L_1 + (1 - \alpha) L_2) = \sum_{i=2}^{n} \phi(\lambda_i(\alpha L_1 + (1 - \alpha) L_2))$$

$$\leq \sum_{i=2}^{n} \phi(\alpha \lambda_i(L_1) + (1 - \alpha) \lambda_i(L_2)).$$  \hspace{1cm} (70)

From (70) and the desired convexity property of $\phi(\cdot)$, we get the convexity property as follows

$$\rho(\alpha L_1 + (1 - \alpha) L_2) \leq \sum_{i=2}^{n} \phi(\alpha \lambda_i(L_1) + (1 - \alpha) \lambda_i(L_2))$$

$$\leq \alpha \sum_{i=2}^{n} \phi(\lambda_i(L_1)) + (1 - \alpha) \sum_{i=2}^{n} \phi(\lambda_i(L_2))$$

$$= \alpha \rho(L_1) + (1 - \alpha) \rho(L_2),$$

for every $0 \leq \alpha \leq 1$. Finally, systemic measure (66) is orthogonal invariant because it is a spectral function. Hence, measure (66) satisfies all properties of Definition 4. This completes the proof of first part.

Next, we show that measure (67) satisfies Properties 1, 2, and 3 given by Definition 4. Similar to the previous case, it is straightforward to verify that measure (67) has Property 1. Now we show that measure (67) has Property 2, i.e., it is a convex function over the set of Laplacian matrices. By hypothesis, $\phi(\cdot)$ is a homogeneous function of order $-\kappa$, therefore, we have

$$\phi(\lambda_i) = \lambda_i^{-\kappa} \phi(1).$$  \hspace{1cm} (71)

Using (71) and (67), we get

$$\rho(L) = K \left( \sum_{i=2}^{n} \lambda_i^{-\kappa} \right)^{\frac{1}{\kappa}},$$

(72)

where $K = \sqrt[\kappa]{\phi(1)}$. It is well-known function (72) is convex for $\lambda_i > 0$ for $i = 2, \ldots, n$ and $\kappa > 1$. Based on the proof of Part (i), measure $\rho^\kappa(\cdot)$ is a Schur-convex function. Consequently, we get

$$\rho(\alpha L_1 + (1 - \alpha) L_2) \leq$$

...
where straightforward to show that every two graphs in

\[ n \sum_{i=2}^{\infty} (\alpha \lambda_i(L_1) + (1 - \alpha) \lambda_i(L_2))^{-n} \]

Now using (74) and the convexity of (22) with respect to \( \lambda_i \)'s, we have

\[
\rho(\alpha L_1 + (1 - \alpha)L_2) \\
\leq K \left( \sum_{i=2}^{\infty} (\alpha \lambda_i(L_1) + (1 - \alpha) \lambda_i(L_2))^{-n} \right)^{\frac{1}{n}} \\
\leq \alpha \rho(L_1) + (1 - \alpha) \rho(L_2).
\]

This completes the proof. \( \blacksquare \)

There are several important examples of performance measures that belong to this class.

1) Spectral Zeta Functions: For a given network (6)-(7), its corresponding spectral zeta function of order \( q \geq 1 \) is defined by

\[ \zeta_q(L) := \left( \sum_{i=2}^{\infty} \lambda_i^{-q} \right)^{\frac{1}{q}}, \quad (74) \]

where \( \lambda_2, \ldots, \lambda_n \) are eigenvalues of \( L \) [38]. According to Assumption 2 all the Laplacian eigenvalues \( \lambda_2, \ldots, \lambda_n \) are strictly positive and, as a result, function (74) is well-defined. The spectral zeta function of a graph captures all its spectral features. In fact, it is straightforward to show that every two graphs in \( \mathcal{L}_n \) with identical zeta functions for all parameters \( q \geq 1 \) are isospectral [7].

Since \( \zeta(\lambda) = \lambda^{-q} \) for \( q \geq 1 \) is a decreasing convex function, the spectral function (74) is a systemic performance measure according to Theorem 11. The systemic performance measure \( \zeta(L) \) is equal to the \( H_2 \)-norm squared of a first-order consensus network (6)-(7) and \( \sqrt{\zeta(L)} \) equal to the \( H_2 \)-norm of a second-order consensus model of a network of multiple agents (c.f. 2).

2) Gamma Entropy: The notion of gamma entropy arises in various applications such as the design of minimum entropy controllers and interior point polynomial-time methods in convex programming with matrix norm constraints [40]. As it is shown in [41], the notion of gamma entropy can be interpreted as a performance measure for linear time-invariant systems with random feedback controllers by relating the gamma entropy to the mean-square value of the closed-loop gain of the system.

Definition 9: The gamma-entropy of network (6)-(7) is defined as

\[ I_y(L) := \frac{1}{\gamma} \int_{-\infty}^{\infty} \log \det \left( I - \gamma^{-2} G(j\omega) G^*(j\omega) \right) d\omega \quad \text{for} \quad \gamma \geq \|G\|_{\mathcal{H}_2}, \]

where \( G(j\omega) \) is the transfer function of network (6)-(7) from \( x \) to \( y \).

Theorem 12: For a given linear consensus network (6)-(7), the value of the gamma-entropy can be explicitly computed in terms of network’s Laplacian eigenvalues as follows

\[ I_y(L) = \begin{cases} \\
\sum_{i=2}^{\infty} f_i(\lambda_i) & \gamma \geq \lambda_2^{-1} \\
\frac{1}{2} & \text{otherwise}
\end{cases} \]

(75)

where \( f_i(\lambda_i) = \gamma^2 \left( \lambda_i - (\lambda_i^2 - \gamma^{-2}) \right) \). Moreover, the gamma-entropy \( I_y(L) \) is a systemic performance measure.

\[ \frac{(\alpha^2 - a^2)^{\frac{1}{2}}}{2a} = \lim_{a \to 0} \frac{\alpha (x^2 - a^2)^{\frac{1}{2}}}{2a} = \frac{1}{2} x^{-1}, \]

for all \( x > 0 \) to prove that \( \lim_{\gamma \to \infty} I_y(L) = \frac{1}{2} \sum_{i=2}^{\infty} \lambda_i^{-1} \). Finally, we use [14] Th. 1 to show that \( \frac{1}{2} \sum_{i=2}^{\infty} \lambda_i^{-1} = \|G\|_{\mathcal{H}_2}^2 = \lim_{\gamma \to \infty} \mathbb{E} \{ y(t)^2(t) \} \).

3) Expected Transient Output Covariance: We consider a transient performance measure at time instant \( t > 0 \) that is defined by

\[ \tau_t(L) := \mathbb{E} \{ y(t)^2(t) \}, \quad (80) \]
where it is assumed that each $\xi_i(t)$ for all $t \geq 0$ is a white Gaussian noise with zero mean and unit variance and all $\xi_i$’s are independent of each other.

In the following, we show that this performance measure is a spectral function of Laplacian eigenvalues.

**Theorem 14:** For a given linear consensus network \([6]-[7]\), the transient measure can be expressed as

$$\tau_t(L) = \sum_{i=2}^{n} \frac{1-e^{-\lambda_i t}}{2\lambda_i}. \quad (81)$$

Moreover, $\tau_t(L)$ is a systemic performance measure for all $t > 0$.

**Proof:** The covariance matrix of the output vector is governed by the following matrix differential equation

$$\dot{Y}(t) = -LY(t) - Y(t) L + M_n, \quad (82)$$

where $Y(t) = \text{cov}(y(t), y(t))$. Using the closed-form solution of \([82]\), which is given by

$$Y(t) = \int_0^t e^{-L\tau} M_n e^{-L\tau} d\tau, \quad (83)$$

we get

$$E\{y^T(t)y(t)\} = Tr(Y(t)) = Tr \left( \int_0^t e^{-L\tau} M_n e^{-L\tau} d\tau \right) = \sum_{i=2}^{n} \int_0^t e^{-2\lambda_i \tau} d\tau = \sum_{i=2}^{n} \frac{1-e^{-\lambda_i t}}{2\lambda_i}. \quad (84)$$

Since $f(x) = \frac{1-e^{-x}}{2e}$ is convex and decreasing with respect to $x$ on $\mathbb{R}_+$, we can conclude that $\tau_t(L)$ is a systemic performance measure according to Theorem \([11]\).

We note that when $t$ tends to infinity, the value of the transient performance measure becomes equal to the $H_2$-norm squared of the network, i.e., $\tau_\infty(L) = \|G\|_H^2$.

4) **Hankel Norm:** The Hankel norm of a network with \([6]-[7]\) and transfer function $G(j\omega)$ from $\xi$ to $y$ is defined as the $L_2$-gain from past inputs to the future outputs, i.e.,

$$\|G\|_H^2 := \sup_{\xi \in L_2(-\infty,0]} \frac{\int_0^\infty Y^T(t)y(t) dt}{\int_0^\infty X(t)\xi(t) dt}. \quad (85)$$

The value of the Hankel norm of network \([6]-[7]\) can be equivalently computed using the Hankel norm of its disagreement form \([43]\) that is given by

$$\dot{x}_d(t) = -L\tau x_d(t) + M_n \xi(t), \quad (85)$$

$$\dot{y}(t) = M_n x_d(t), \quad (86)$$

where the disagreement vector is defined by

$$x_d(t) := M_n x(t) = x(t) - \frac{1}{n} J_n x(t). \quad (87)$$

The disagreement network \([85]-[86]\) is stable as every eigenvalue of the state matrix $-L\tau = -(L + \frac{1}{n} J_n)$ has a strictly negative real part. One can verify that the transfer functions from $\xi(t)$ to $y(t)$ in both realizations are identical. Therefore, the Hankel norm of the system from $\xi(t)$ to $y(t)$ in both representations are well-defined and equal, and is given by

$$\eta(L) := \|G\|_H = \sqrt{\lambda_{\text{max}}(PQ)}, \quad (88)$$

where the controllability Gramian $P$ is the unique solution of

$$(L + \frac{1}{n} J_n) P + P(L + \frac{1}{n} J_n) - M_n = 0$$

and the observability Gramian $Q$ is the unique solution of

$$Q(L + \frac{1}{n} J_n) + (L + \frac{1}{n} J_n) Q - M_n = 0.$$

**Theorem 15:** The value of the Hankel norm of consensus network \([6]-[7]\) is equal to

$$\eta(L) = \frac{1}{2} \lambda_2^{-1}$$

and it is a systemic performance measure.

**Proof:** According to the definition \([88]\), we get

$$\eta(L) = \sqrt{\lambda_{\text{max}}(PQ)} = \sqrt{\lambda_{\text{max}}((L\tau)^2)} = \lambda_2^{-1}. \quad (89)$$

Moreover, based on Theorem \([11]\) we know that the spectral zeta function $\zeta(L)$ is a systemic performance measure for all $1 \leq q \leq \infty$. Therefore by setting $q = \infty$, we have

$$\eta(L) = \frac{1}{2} \zeta_{\infty}(L) = \frac{1}{2} \lim_{q \to \infty} \zeta_q(L) = \frac{1}{2} \lambda_2^{-1}. \quad (90)$$

As a result, $\eta(L)$ is a systemic performance measure.

5) **Uncertainty volume:** The uncertainty volume of the steady-state output covariance matrix of consensus network \([6]-[7]\) is defined by

$$|\Sigma| := \det \left( Y_\infty + \frac{1}{n} J_n \right), \quad (89)$$

where

$$Y_\infty = \lim_{t \to \infty} E\{y(t)y^T(t)\}. \quad (90)$$

This quantity is widely used as an indicator of the network performance \([11], [45]\). Since $y(t)$ is the error vector that represents the distance from consensus, the quantity \([89]\) is the volume of the steady-state error ellipsoid.

**Theorem 16:** For a given consensus network \([6]-[7]\) with Laplacian matrix $L$, the logarithm of the uncertainty volume, i.e.,

$$v(L) := \log |\Sigma| = (1-n) \log 2 - \sum_{i=2}^{n} \log \lambda_i \quad (90)$$

is a systemic performance measure.

**Proof:** According to the dynamics of the network \([6]-[7]\), the time evolution of the mean and the covariance matrix of the state vector are governed by

$$\dot{\bar{y}}(t) = -\left( L + \frac{1}{n} J_n \right) y(t), \quad (91)$$

and

$$\dot{Y}(t) = -LY(t) - Y(t) L + M_n, \quad (92)$$

where $\bar{y}(t) = E(y(t))$ and $Y(t) = \text{cov}(y(t), y(t))$. From \([91]\), it follows that

$$\bar{y}(\infty) = \lim_{t \to \infty} \bar{y}(t) = 0. \quad (93)$$

Consequently, using \([92]\) and \([93]\) we get

$$Y_\infty = \lim_{t \to \infty} \text{cov}(y(t), y(t)) = \frac{1}{2} L^\dagger. \quad (94)$$

Finally, by substituting $Y_\infty$ in \([89]\), we get

$$|\Sigma| = \det \left( Y_\infty + \frac{1}{n} J_n \right) = \det \left( \frac{1}{2} L^\dagger + \frac{1}{n} J_n \right) = 2^{-n+1} \prod_{i=2}^{n} \lambda_i^{-1}. \quad (95)$$

From this result and the definition of $v(L)$, one concludes that

$$v(L) = \log 2^{-n+1} \prod_{i=2}^{n} \lambda_i^{-1} = (n-1) \log 2 - \sum_{i=2}^{n} \log \lambda_i.$$
Because \( -\log(.) \) is convex and decreasing in \( \mathbb{R}_{++} \), the quantity
\[
v(L) = (n - 1) \log 2 = -\sum_{i=2}^{n} \log \lambda_i,
\]
is a systemic performance measure according to Theorem 11. Note that \((n - 1) \log 2\) is a constant number. Therefore, we conclude that \(v\) is a systemic performance measure.

### B. Hardy-Schatten Norms of Linear Systems

The \(p\)-Hardy-Schatten norm of network (6)-(7) for \(1 < p \leq \infty\) is defined by
\[
\|G\|_{\mathcal{H}_p} := \left\{\frac{1}{2\pi} \int_{-\infty}^{\infty} \sum_{k=1}^{n} \sigma_k(G(j\omega))^p \, d\omega\right\}^{\frac{1}{p}},
\]
(94)
where \(\sigma_k(G(j\omega))\) is the transfer matrix of the network from \(\xi\) to \(y\) and \(\sigma_k(G)\) for \(k = 1, \ldots, n\) are singular values of \(G(j\omega)\). It is known that this class of system norms captures several important performance and robustness features of linear time-invariant systems [46]-[48]. For example, a direct calculation shows [14] that the \(H_2\)-norm of linear consensus network (6)-(7) can be expressed as
\[
\|G\|_{H_2} = \left(\frac{1}{2} \sum_{i=2}^{n} \lambda_i^{-1}\right)^{\frac{1}{2}}.
\]
(95)
This norm has been also interpreted as a notion of coherence in linear consensus networks [1]. The \(H_\infty\)-norm of network (6)-(7) is an input-output system norm [49] and its value can be expressed as
\[
\|G\|_{H_\infty} = \lambda_2^{-1},
\]
(96)
where \(\lambda_2\) is the second smallest eigenvalue of \(L\), also known as the algebraic connectivity of the underlying graph of the network. The \(H_\infty\)-norm (96) can be interpreted as the worst attainable performance against all square-integrable disturbance inputs [50].

**Theorem 17:** The \(p\)-Hardy-Schatten norm of a given consensus network (6)-(7) is a systemic performance measure for every exponent \(2 \leq p \leq \infty\). Furthermore, the following identity holds
\[
\|G\|_{H_p} = (\zeta_{p-1}(L))^{1-\frac{1}{p}},
\]
(97)
where \(\zeta_{p-1} = \sqrt{-\beta(\frac{p}{2} - 1)}\) and \(\beta : \mathbb{R} \times \mathbb{R} \rightarrow \mathbb{R}\) is the well-known Beta function.

**Proof:** We utilize the disagreement form of the network that is given by (85)-(86) and the decomposition (75) to compute the \(H_p\)-norm of \(G(j\omega)\) as follows
\[
\|G\|_{H_p} = \frac{1}{2\pi} \int_{-\infty}^{\infty} \sum_{k=1}^{n} \sigma_k(G(j\omega))^p \, d\omega
\]
\[
= \frac{1}{2\pi} \sum_{i=2}^{n} \int_{-\infty}^{\infty} \left(\frac{1}{\omega^2 + \lambda_i^2}\right)^{\frac{p}{2}} d\omega
\]
\[
= \frac{-1}{\beta(\frac{p}{2} - 1)} \sum_{i=2}^{n} \lambda_i^{-\frac{p}{2} - 1} = \frac{-1}{\beta(\frac{p}{2} - 1)} \zeta_{p-1}(L)^{-\frac{1}{p}},
\]
for all \(2 \leq p \leq \infty\). Now we show that measure (97) satisfies Properties 1, 2, and 3 in Definition 4. Similar to the proof of Theorem 11 it is straightforward to verify that measure (97) has Property 1. Next we show that measure (97) has Property 2, i.e., it is a convex function over the set of Laplacian matrices. We then show that for all \(2 \leq p \leq \infty\) the following function \(f : \mathbb{R}_{++} \rightarrow \mathbb{R}\) is concave
\[
f(x) = \left(\sum_{i=2}^{n} x_i^{-p+1}\right)^{-\frac{1}{p-1}},
\]
where \(x = [x_2, x_3, \ldots, x_n, 1]^T\). To do so, we need to show \(\nabla^2 f(x) \preceq 0\), where the Hessian of \(f\) is given by
\[
\frac{\partial^2 f(x)}{\partial x_i^2} = -\frac{p}{x_i} \left(\frac{f(x)}{x_i}\right)^{p} + \frac{p}{f(x)} \left(\frac{f(x)}{x_i}\right)^{p} \quad \text{and}
\]
\[
\frac{\partial^2 f}{\partial x_i \partial x_j} = \frac{p}{f(x)} \left(\frac{f(x)}{x_i x_j}\right)^{p}.
\]
The Hessian matrix can be expressed as
\[
\nabla^2 f(x) = \frac{p}{f(x)} \left(\nabla \log(z) \right)^T \nabla \log(z) + z^T
\]
(98)
where
\[
z = (f(x)/x_2, \ldots, (f(x)/x_n))^T.
\]
To verify \(\nabla^2 f(x) \preceq 0\), we must show that for all vectors \(v\), \(v^T \nabla^2 f(x) v \leq 0\). We know that
\[
v^T \nabla^2 f(x) v = \frac{p}{f(x)} \left(\sum_{i=1}^{n-1} v_i \frac{n-i}{n-i} v_i^2 + \sum_{i=1}^{n} v_i z_i \right)^2.
\]
Using the Cauchy-Schwarz inequality \(a^T b \leq \|a\|\|b\|_2\), where
\[
a_i = \left(\frac{f(x)}{x_i}\right)^{\frac{1}{p}} = z_i^{\frac{1}{p}},
\]
and \(b_i = z_i^{1-p} v_i\), it follows that \(v^T \nabla^2 f(x) v \leq 0\) for all \(v \in \mathbb{R}^{n-1}\). Therefore, \(f(x)\) is concave. Let us define \(h(x) = x^{-\frac{1}{p}}\), where \(x \in \mathbb{R}\). Since \(f(.)\) is positive and concave, and \(h\) is decreasing convex, we conclude that \(h(f(.)\) is convex [50]. Hence, we get that \(\|G\|_{H_p}\) is a convex function with respect to the eigenvalues of \(L\). Since this measure is a symmetric closed convex function defined on a convex subset of \(\mathbb{R}^{n-1}\), i.e., \(n-1\) nonzero eigenvalues, according to [50] we conclude that \(\|G\|_{H_p}\) is a convex of Laplacian matrix \(L\). Finally, measure \(\|G\|_{H_p}\) is orthogonal invariant because it is a spectral function as shown in (97). Hence, this measure satisfies all properties of Definition 4. This completes the proof.

Milad Siami received his dual B.Sc. degrees in electrical engineering and pure mathematics from Sharif University of Technology in 2009, M.Sc. degree in electrical engineering from Sharif University of Technology in 2011, and M.Sc. and Ph.D. degrees in mechanical engineering from Lehigh University in 2014 and 2017, respectively. From 2009 to 2010, he was a research student at the National Institute of Science and Technology (INSA), France. From 2011 to 2012, he was a research student at the Department of Mechanical and Environmental Informatics at the Tokyo Institute of Technology, Tokyo, Japan. He is currently a postdoctoral associate in the Institute for Data, Systems, and Society at MIT. His research interests include distributed control systems, distributed optimization, and applications of fractional calculus in engineering. He received a Gold Medal at the 2013 International Mathematical Olympiad, Iran (2003) and the Best Student Paper Award at the 5th IFAC Workshop on Distributed Estimation and Control in Networked Systems (2015). Moreover, he was awarded RCEAS Fellowship (2012), Blythesly Fellowship (2013), Rossin College Doctoral Fellowship (2015), and Graduate Student Merit Award (2016) at Lehigh University.

Nader Motte (S’99-M’08-SM’13) received his B.Sc. degree in Electrical Engineering from Sharif University of Technology in 2000, M.Sc. and Ph.D. degrees from University of Pennsylvania in Electrical and Systems Engineering in 2006 and 2007 respectively. From 2008 to 2011, he was a postdoctoral scholar in the Control and Dynamical Systems Department at Caltech. He is currently an Associate Professor in the Department of Mechanical Engineering and Mechanics at Lehigh University. His current research interests are distributed dynamical and control systems with particular focus on issues related to sparsity, performance, and robustness. He is a past recipient of several awards including the 2008 AACC Hugo Schuck best paper award, the 2007 ACC best student paper award, the 2008 Joseph and Rosaline Wolf best thesis award, a 2013 Air Force Office of Scientific Research Young Investigator Program award (AFOSR YIP), a 2015 NSF Faculty Early Career Development (CAREER) award, and a 2016 Office of Naval Research Young Investigator Program award (ONR YIP).
