On a bounded, measurable domain of non-negative current-quark mass, realistic models of QCD’s gap equation can simultaneously admit two inequivalent dynamical chiral symmetry breaking (DCSB) solutions and a solution that is unambiguously connected with the realisation of chiral symmetry in the Wigner mode. The Wigner solution and one of the DCSB solutions are destabilised by a current-quark mass and both disappear when that mass exceeds a critical value. This critical value also bounds the domain on which the surviving DCSB solution possesses a chiral expansion. This value can therefore be viewed as an upper bound on the domain within which a perturbative expansion in the current-quark mass around the chiral limit is uniformly valid for physical quantities. For a pseudoscalar meson constituted of equal mass current-quarks, it corresponds to a mass \( m_{q_c} \sim 0.45 \text{ GeV} \). In our discussion we employ properties of the two DCSB solutions of the gap equation that enable a valid definition of \( \langle \bar{q}q \rangle \) in the presence of a nonzero current-mass. The behaviour of this condensate indicates that the essentially dynamical component of chiral symmetry breaking decreases with increasing current-quark mass.

I. INTRODUCTION

Dynamical chiral symmetry breaking (DCSB) is the creation, via interactions with the gauge field alone, of a fermion mass gap: whose magnitude exceeds, perhaps by a great amount, the mass-scale in the action set by the fermion’s bare mass; and which persists perhaps by a great amount, the mass-scale in the action

\[ S(p)^{-1} = Z_2 \left( i \gamma \cdot p + m_{\text{bm}} \right) + \Sigma(p), \]

\[ \Sigma(p) = Z_1 \int_q g^2 D_{\mu\nu}(p-q) \frac{\Lambda^2}{2} \gamma_\mu S(q) \Gamma_\nu^a(q, p), \]

where \( Z_2 \) is the dressed-quark-gluon vertex, and \( D_{\mu\nu}(k) \) is the dressed-quark-gluon propagator, \( \Gamma_\nu^a(q, p) \) is the dressed-quark-gluon vertex, and \( m_{\text{bm}} \) is the quark’s \( \Lambda \)-dependent bare current-mass. The quark-gluon-vertex and quark wave function renormalisation constants, \( Z_{1,2}(\Lambda^2, \Lambda^2) \), depend on the renormalisation point, \( \Lambda \), the regularisation mass-scale and the gauge parameter.

The solution of the gap equation can be written in the following equivalent forms:

\[ S(p) = \frac{1}{i \gamma \cdot p A(p^2, \Lambda^2) + B(p^2, \Lambda^2)} = \frac{Z(p^2, \Lambda^2)}{i \gamma \cdot p + M(p^2)} \]

\[ = -i \gamma \cdot p \sigma_\nu(p^2, \Lambda^2) + \sigma_S(p^2, \Lambda^2). \]
from Eq. (1) augmented by the renormalisation condition
\[ S(p)^{-1}|_{p^2=c^2} = i\gamma \cdot p + m(\zeta), \]
where \( m(\zeta) \) is the renormalised (running) mass:
\[ Z_2(\zeta^2, \Lambda^2) m_{\text{BM}}(\Lambda) = Z_4(\zeta^2, \Lambda^2) m(\zeta), \]
with \( Z_4 \) the Lagrangian-mass renormalisation constant. In QCD the chiral limit is strictly and unambiguously defined by [\ref{1}, \ref{14}]
\[ Z_2(\zeta^2, \Lambda^2) m_{\text{BM}}(\Lambda) \equiv 0, \forall \Lambda \gg \zeta, \]
which states that the renormalisation-point-invariant current-quark mass \( \bar{m} = 0 \).

QCD’s action is chirally invariant in the chiral limit. Consider a global chiral transformation applied to one particular flavour of quark, characterised by an angle \( \theta \). Under this operation the quark’s propagator is modified:
\[ S(p) \to e^{i\theta \gamma_5} S(p) e^{i\theta \gamma_5} = -i\gamma \cdot p \sigma V(p^2) + e^{2i\theta \gamma_5} \sigma_S(p^2). \]

Suppose DCSB takes place so that \( B(p^2, \zeta^2) \neq 0 \).
\[ \text{Then, with the choice } \theta = \pi/2, \text{ Eq. (2) corresponds to mapping } B(p^2, \zeta^2) \to -B(p^2, \zeta^2). \]
It follows that if \( B(p^2, \zeta^2) \) is a solution of the gap equation in the chiral limit, then so is \( -B(p^2, \zeta^2) \).

While these two solutions are distinct, the chiral symmetry entails that each yields the same pressure [\ref{18}]. Hence they correspond to equivalent vacua. This is an analogue of the chiral-limit equivalence between the \((\sigma = 1, \pi = 0)\) vacua in the linear-sigma-model, as elucidated in Refs. \[19, 20\]. It is notable that, more generally, given a solution of the \( m(\zeta) > 0 \) gap equation characterised by \( \{ m_1(\zeta), m_2(\zeta), m_3(\zeta) \} \), then \( \{ -m_1(\zeta), m_2(\zeta), -m_3(\zeta) \} \) is a solution of the gap equation obtained with \( -m(\zeta) \).

Studies of DCSB have hitherto focused on a positive definite solution of the gap equation because the introduction of a positive current-quark bare-mass favours this solution; viz., if another solution exists, then it has a lower pressure. Returning again to the sigma-model analogy, such a bare-mass tilts the so-called wine-bottle potential, producing a global minimum at \( (\sigma = 1, \pi = 0) \).

However, whether the massive gap equation admits solutions other than that which is positive definite, the effect of the current-quark mass on such solutions, and their interpretation, are questions little considered.

III. EXEMPLARY

To begin addressing these questions, we first consider the simple example defined by Eqs. (1), \[\ref{2}\] with the following forms for the dressed-gluon propagator and quark-gluon vertex:
\[ g^2 D_{\mu\nu}(p-q) = \delta_{\mu\nu} \frac{1}{m_G^2} \theta(\bar{\Lambda}^2 - q^2), \]
\[ \Gamma^a_\nu(q,p) = \gamma_\nu \frac{\lambda_a^2}{2}, \]
wherein \( m_G \) is some “gluon” mass-scale and \( \bar{\Lambda} \) serves as a cutoff [\ref{21}]. The model thus defined is not renormalisable so that the regularisation scale \( \bar{\Lambda} \), upon which all calculated quantities depend, plays a dynamical role and the renormalisation constants can be set to one. In the model thus defined the gap equation is
\[ i\gamma \cdot p A(p^2) + B(p^2) = i\gamma \cdot p + m_{\text{BM}} \]
\[ + \frac{4}{3} \int \frac{d^4q}{(2\pi)^4} \theta(\bar{\Lambda}^2 - q^2) \gamma_\mu \frac{-i\gamma \cdot q A(q^2) + B(q^2)}{q^2 A^2(q^2) + B^2(q^2)} \gamma_\mu. \]

This gap equation’s solution is \( A(p^2) \equiv 1 \) and \( B(p^2) = M \), a constant which satisfies
\[ M = m_{\text{BM}} + M \frac{1}{3\pi^2} \frac{1}{m_G^2} C(M^2, \bar{\Lambda}^2). \]
\[ C(M^2, \bar{\Lambda}^2) = \bar{\Lambda}^2 - M^2 \ln \left[ 1 + \frac{\bar{\Lambda}^2}{M^2} \right]. \]

Since \( \bar{\Lambda} \) defines the mass-scale in a nonrenormalisable model, we can set \( \bar{\Lambda} \equiv 1 \) and hereafter interpret all other mass-scales as being expressed in units of \( \Lambda \), whereupon the gap equation becomes
\[ G(M) := M - m_{\text{BM}} - M \frac{1}{3\pi^2} \frac{1}{m_G^2} C(M^2, 1) = 0. \]

Equation (13) admits a \( M \neq 0 \) solution when \( m_{\text{BM}} = 0 \) and if only if
\[ m_G^2 < (m_G^2)^2 = \frac{1}{3\pi^2}; \]
namely, it supports DCSB in this case. Hence, to proceed we choose
\[ m_G^2 = \frac{3}{4} \frac{1}{3\pi^2}. \]

NB. For \( m_G > m_G^2 \) the only solution of the gap equation is one that may be obtained via a perturbative expansion in the coupling and hence DCSB is impossible. That domain is therefore not of interest herein.

\( G(M) \) is plotted in Fig. (1) One reads from the figure that in the chiral limit there are three solutions to the gap equation:
\[ M = \{ \begin{cases} M_W = 0, \\ M_\pm = \pm M^0 = \pm 0.33. \end{cases} \]

\( M_W \) describes a realisation of chiral symmetry in the Wigner mode. It corresponds to the vacuum configuration in which the possibility of DCSB is not realised; i.e., \( \sigma = 0 = \pi \) in the sigma-model analogy. In the chiral limit this is the only solution accessible via a perturbative expansion in the coupling. The solutions \( M_\pm \) are essentially nonperturbative. They represent the realisation of chiral symmetry in the Nambu-Goldstone mode; namely, DCSB.
These solutions exist on a domain defined by Eqs. (13), (15). Solid curve: obtained with \( m_{bm} = 0 \), in which case \( G(M) \) is odd under \( M \to -M \); long-dashed curve: \( m_{bm} = 0.01 \); short-dashed curve: \( m_{bm} = m_{cr}^{bm} = 0.033 \); dotted curve: \( m_{bm} = 0.05 \). (All dimensioned quantities in units of \( \tilde{\Lambda} \).)

It is apparent in Fig. 1 that with the gap equation obtained via Eqs. (8), (9), each of the solutions identified in Eq. (16) evolves smoothly with current-quark mass on a neighbourhood of \( m_{bm} = 0 \). We subsequently consider the manner in which these solutions evolve as \( m_{bm} \) is increased from zero. In that discussion we will retain the labels introduced in Eq. (16) and attach them to that solution which is (pointwise, if relevant) closest in magnitude to the chiral limit solution of the same name.

\( M = M_+ > 0 \) is the solution usually tracked in connection with QCD phenomenology. In models of this type it is identified as a constituent-quark mass. As \( m_{bm} \) is increased, \( M_+ \) also increases.

As evident in Fig. 1 the other two solutions of the gap equation do not immediately disappear when \( m_{bm} \) increases from zero. Nor do they always persist. Instead, these solutions exist on a domain

\[
D(m_{bm}) = \{ m_{bm} \mid 0 \leq m_{bm} < m_{cr}^{bm} \}. \tag{17}
\]

\( M_W, M_- \) also evolve smoothly with \( m_{bm} \). Moreover, at the critical current-quark mass, \( m_{cr}^{bm} \), these two solutions coalesce.

To understand the origin of a critical mass we observe from Eq. (13) and Fig. 1 that introducing a current-quark mass merely produces a constant pointwise negative shift in the curve \( G(M) \). Hence, the critical current-quark mass is that value of this mass for which \( G(M) = 0 \) at its local maximum. The local maximum occurs at

\[
M_{lm} = \{ M \mid M < 0, G'(M) = 0 \} \tag{18}
\]

and therefore in the present illustration the critical current-quark mass

\[
m_{cr}^{bm} = \{ m_{bm} \mid G(M_{lm}) = 0 \} = 0.033. \tag{19}
\]

We now return to the behaviour of \( M_+ \) and ask whether this quantity has a power series expansion in \( m_{bm} \) about \( m_{bm} = 0 \); viz., a chiral expansion:

\[
M_+(m_{bm}) = M_0 + \sum_{n=1}^{\infty} a_n(m_{bm})^n. \tag{20}
\]

Such an expansion exists; i.e., is absolutely convergent on a measurable domain, so long as \( \forall n \)

\[
\left( \frac{1}{|a_n|} \right)^{1/n} > \left( \frac{1}{|a_{n+1}|} \right)^{1/(n+1)} \tag{21}
\]

and

\[
m_{rc} := \lim_{n \to \infty} \left( \frac{1}{|a_n|} \right)^{1/n} > 0, \tag{22}
\]

where the quantity \( m_{rc} \) is the radius of convergence for the series; i.e., the series converges on \( 0 \leq m_{bm} < m_{rc} \).

To determine whether \( M_+ \) has such an expansion we inserted Eq. (20) into Eq. (13) and solved the sequence of algebraic equations that this produces to obtain the coefficients \( \{a_1, \ldots, a_{14}\} \). The procedure is straightforward but we stopped at \( n = 14 \) because the magnitude of the coefficients grows rapidly with \( n \); e.g., \( a_{14} = -4.27331 \times 10^{17} \), and this order was sufficient for our purpose. The information depicted in Fig. 2 indicates that \( M_+ \) does have a chiral expansion with a nonzero but finite radius of convergence. The curve in the figure is the function \( (m = 1 \text{ diagonal Padé}) \)

\[
u_0 + \frac{u_1 t}{1 + u_2 t}, \quad u_0 = 0.326, \quad u_1 = 0.295, \quad u_2 = -0.596, \tag{23}
\]

where the coefficients were fixed in a least-squares fit to \( \{(1/a_n)^{1/n}, n = 2, \ldots, 14\} \). The limit \( t \to 0 \) corresponds to \( n \to \infty \) and hence the value of \( u_0 \) gives the radius
of convergence. We repeated the fit with diagonal Padé approximants of order \( m = 2, 3, 4 \). Combining the results, we obtain the radius of convergence for the chiral expansion of \( M_+ \):

\[
m_{rc} = 0.034 \pm 0.001 = m_{cr}^{bm}
\]

(24)

within numerical error. Hence \( \mathcal{D}(m^{bm}) \) is also the domain on which \( M_+ \) has a chiral expansion. (NB. Analogous chiral expansions exist within this domain for \( M_W, M_- \). The expansion for \( M_W \) vanishes for \( m^{bm} = 0 \) whereas the leading term in that for \( M_- \) is \( M_0 \). We emphasise that \( M_\pm \) have chiral expansions around the solution that is nonperturbative in the coupling. A nonzero value of \( M_0 \) is never attainable via an expansion in the coupling.)

The two combinations

\[
\hat{M} := \frac{1}{2}(M_+ - M_-), \quad \bar{M} := \frac{1}{2}(M_+ + M_-)
\]

(25)

are of interest. In the chiral limit, \( \hat{M} = M^0 \) and \( \bar{M} = M_W \). The evolution of each with current-quark mass is depicted in Fig. 3. It is apparent that \( \hat{M} \) is continuous on \( \mathcal{D}(m^{bm}) \) and evolves from the DCSB solution with increasing \( m^{bm} \); \( \hat{M}(m^{bm}) \) is a monotonically decreasing function. These features can be understood as illustrating that the essentially dynamical component of chiral symmetry breaking decreases with increasing current-quark mass. This has also been argued via the constituent-quark \( \sigma \)-term; e.g., in Sec. 5.2.2 of Ref. [22].

The alternative combination, \( \bar{M} \), is also continuous on \( \mathcal{D}(m^{bm}) \). With the value of the coupling given in Eq. (13), \( \bar{M}(m^{bm}) \) evolves from the Wigner solution according to

\[
\hat{M} \stackrel{m^{bm} \to 0}{\approx} m^{bm} \left[ 1 + \frac{2}{3} \frac{3(M^0)^2 - 1}{(M^0)^2 + 1} \right] + \ldots
\]

(26)

The development of \( \hat{M}(m^{bm}) \) might be viewed as a gauge of the destabilising effect that DCSB has on this model’s Wigner mode.

We now return to the critical current-quark mass, Eq. (19), (24). In the neighbourhood of \( m^{bm} = 0 \),

\[
M_W(m^{bm}) = -3 m^{bm} + \ldots
\]

(27)

viz., \( M_W(m^{bm}) \) can be expressed as a power series in \( m^{bm} \) around its chiral limit value, where that value is perturbative in the coupling. However, with increasing current-quark mass \( M_W \) decreases steadily toward \( M_- \), which is nonzero in the chiral limit and essentially nonperturbative in the coupling, until at \( m_{cr}^{bm} \), \( M_W = M_- \). At this point a solution whose small current-quark mass behaviour is essentially perturbative has melded with a solution that is inaccessible in perturbation theory and actually characteristic of DCSB. A related view sees \( M_- \) as a DCSB solution whose modification by a current-quark mass can no longer be evaluated as a power series in \( m^{bm} \) when that mass exceeds \( m_{cr}^{bm} \). Finally, a chiral expansion of \( M_+ \) can only converge for current-quark masses less than \( m_{cr}^{bm} \).

These observations suggest that \( m_{cr}^{bm} \) specifies the upper bound on the domain within which, for physically relevant quantities, a perturbative expansion in the current-quark mass around their chiral limit values can be valid; i.e., it is a (possibly weak) upper bound on the radius of convergence. This view and the numerical result in Eq. (19) coincide with Ref. [24]. We will return to this point.

IV. CLOSER TO QCD

It is natural to ask whether analogous behaviour exists in QCD. To explore this we work with a renormalisation-group-improved (RGI) rainbow truncation of the gap equation’s kernel. This is the leading-order in a systematic and symmetry-preserving truncation of the DSEs that is nonperturbative in the coupling [24, 25, 26, 27], and references thereto, and an efficacious implementation preserves the one-loop ultraviolet behaviour of perturbative QCD. However, a model assumption is required for the behaviour of the kernel in the infrared; viz., on the interval \( Q^2 \lesssim 1 \) GeV\(^2\), which corresponds to length-scales \( \gtrsim 0.2 \) fm.

The rainbow truncation is realised in the gap equation via the replacement of Eq. (2) by [17]

\[
\Sigma(p) = \int_q \mathcal{G}((p - q)^2) D_{\mu\nu}^{\text{free}}(p - q) \frac{\lambda^a}{2} \gamma_\mu S(q) \frac{\lambda^a}{2} \gamma_\nu.
\]

(28)

Herein we employ the model interaction introduced in
precisely as prescribed by QCD. On the other hand, the
Richardson-like potential [33] between static sources.
may be obtained [35, 36, 37]. This interpretation, when combined with the result that in a
heavy-quark–heavy-antiquark BSE the RGI ladder truncation preserves the one-loop renormalisation group
properties of QCD the ultraviolet behaviour of the solution, is analogous to

![Figure 4: Evolution with current-quark mass, \(m(\zeta_{19})\), of \(A(p^2 = 0, \zeta^2)\) (dimensionless), \(B(p^2 = 0, \zeta^2)\) (GeV) as calculated with \(\omega = 0.4\) GeV in Eq. (29): solid curve – \(B_0(0)\); dash-dotted curve – \(A_0(0)\); long dashed curve – \(B_0(0)\); sparse dotted curve – \(A_0(0)\); short dashed curve – \(B_W(0)\); dense dotted curve – \(A_W(0)\).](image)

the phenomenological success of the RGI rainbow-ladder truncation. The truncation preserves the feature that if \(M_+(p^2) = M(p^2) > 0\), \(\forall p^2 > 0\), is a solution of the chiral-limit gap equation, then so is \(M_-(p^2) = [-M(p^2)]\). These solutions are the analogues of \(M_{\pm}\) in Eq. (16).

We solve the gap equation using the Pauli-Villars regularisation procedure described in Ref. [38] and work in Landau gauge because it is a fixed point of the renormalisation group. The renormalisation condition, Eq. (4), is implemented at \(\zeta = \zeta_{19} : = 19\) GeV with a choice for the current-quark mass. This scale is deep in the perturbative (weak-coupling) domain and hence a renormalisation-group-invariant current-quark mass is unambiguously specified via Eq. (34). For reference, we also list below current-quark masses defined therewith via one-loop evolution to a “typical hadron scale”; viz.,

\[
m(\zeta_1) := \frac{\hat{m}}{(\ln \zeta_1 / \Lambda_{\text{QCD}})^{\gamma_m}} : \zeta_1 = 1\ \text{GeV}.
\]

It is apparent in Fig. 4 that this interaction model, too, exhibits a bounded domain of current-quark mass on which \(M_-(p^2)\) and \(M_+(p^2)\) exist simultaneously:

\[
D(\hat{m}) = \{\hat{m} | 0 \leq \hat{m} < \hat{m}_{\text{cr}}\}.
\]

Away from the chiral limit the solution characterised by \(M_-(p^2)\) describes the propagation characteristics of a quark embedded in an unstable vacuum. The properties of that vacuum may be detailed, e.g., by solving the Bethe-Salpeter equation for meson bound-states

\[
\frac{G(t)}{t} = \frac{4\pi^2}{\omega^6} D t e^{-t/\omega^2} + \frac{8\pi^2 \gamma_m}{\ln \left[\tau + \left(1 + t/\Lambda_{\text{QCD}}^2\right)^2\right]} F(t),
\]

with \(t = k^2\), \(F(t) = [1 - \exp(-t/[4m_F^2])]/t\), \(m_F^2 = 0.5\) GeV, \(\tau = e^2 - 1\), \(\gamma_m = 12/25\) and \(\Lambda_{\text{QCD}} = \Lambda_{\overline{\text{MS}}} = 0.234\). This form expresses the interaction as a sum of two terms. The second ensures that perturbative behaviour is correctly realised at short range; namely, as written, for \((k - q)^2 \sim k^2 \sim q^2 \gtrsim 1 - 2\) GeV^2, Eq. (29) guarantees that the quark-antiquark scattering kernel, \(K\), is precisely as prescribed by QCD. On the other hand, the first term in \(G(t)\) is a model for the long-range behaviour of the interaction. It is a finite width representation of the form introduced in Ref. [31], which has been rendered as an integrable regularisation of \(1/t^2 = 1/k^4\) [32]. This interpretation, when combined with the result that in a heavy-quark–heavy-antiquark BSE the RGI ladder truncation is exact [27], is consistent with \(G(t)\) leading to a Richardson-like potential [33] between static sources.

The two parameters in Eq. (29) are \(D\) and \(\omega\), which together determine the integrated infrared strength of the rainbow kernel. However, they are not independent [30]: in fitting to a selection of ground-state observables, a change in one is compensated by altering the other; e.g., on the interval \(\omega \in [0.3, 0.5]\) GeV, the fitted observables are approximately constant along the trajectory [34]

\[
\omega D = (0.72\text{ GeV})^3. \tag{30}
\]

Equation (29) is thus a one-parameter model.

It is important to bear in mind that because the truncation preserves the one-loop renormalisation group properties of QCD the ultraviolet behaviour of the solutions of Eqs. (1) and (28) is precisely that of QCD. Hence we have

\[
M(p^2) = \frac{\hat{m}}{(4 \ln p^2 / \Lambda_{\text{QCD}}^2)^{\gamma_m}} = B_0(0)\tag{29a}
\]

where \(\hat{m}\) is the renormalisation-group-invariant mass.

The model-dependence is mainly restricted to infrared momenta but on this domain, too, there is good agreement with QCD; e.g., the gap equation solutions are in semiquantitative agreement [34] with numerical simulations of lattice-regularised quenched-QCD. (NB. Precise agreement would be incorrect because Eq. (29a) corresponds to an unquenched theory.) The conditions have been explored under which pointwise agreement between DSE results and quenched- and full-lattice simulations may be obtained [35, 36, 37].

Equations (1) and (28) obviously admit the \(M(p^2) = 0\) solution in the chiral limit, Eq. (6). This solution, which can always be obtained through a weak coupling expansion, is analogous to \(M_{\overline{\text{WS}}}\) in Eq. (16).

In the chiral limit the rainbow gap equation also yields a DCSB solution. This capacity is the basis for much of
solution is not contingent upon the pointwise behaviour of the gap equation’s kernel and supports an interpretation of our findings in the context of QCD. (Indeed, all of the features identified herein are also expressed, e.g., in the model of Ref. [32].) We observe that in the model of this section the Wigner solution is naturally represented by two momentum-dependent functions; namely, \(A_W(p^2, \zeta^2)\), \(B_W(p^2, \zeta^2)\). As indicated by Figs. 1, 2, 4 at \(\hat{m} = \hat{m}_{cr}\) these functions meld pointwise with their counterparts in the DCSB \(M_-(p^2)\) solution.

We emphasise that all solutions of the gap equation evolve smoothly with current-quark mass on the domain specified in Eq. (34). Moreover, the Nambu solution characterised by \(M_+(p^2)\) evolves smoothly for all values of the current-quark mass. Naturally, this does not necessarily entail that it’s pointwise behaviour at a given value of current-quark mass is obtainable via a perturbative expansion in \(\hat{m}\) about the nonzero DCSB result at \(\hat{m} = 0\), which is essentially nonperturbative in the coupling. Indeed, the commonality of behaviour between the two models we discuss explicitly herein, and with the others we have considered, suggests strongly that \(\hat{m}_{cr}\) is the radius of convergence for a pointwise chiral expansion of \(M_+(p^2)\) around the DCSB chiral-limit result. However, verification must wait because the method employed in arriving at Eq. (24) is not workable for the integral gap equation and we do not yet have a tractable alternative.

In considering other rainbow interaction models, we find that \(m_{cr}\) assumes similar values in most models that provide a reasonable description of the same low-energy observables. An exception is the model of Ref. [31], in which a solution with \(B(s = 0) < 0\), and \(A(s)\) and \(B(s)\) continuous on \(s \in [0, \infty)\) exists only in the chiral limit, with the interpretation that in this model \(m_{cr} = 0\).

One might also ask after the effect of dressing the quark-gluon vertex. As noted above, symmetry ensures that in the chiral limit the gap equation simultaneously admits \(M_-(p^2)\) and \(M_+(p^2)\) solutions in this instance, too. The extent of the domain of current-quark mass on which \(M_-(p^2)\) solution persists will probably depend on the structure of the vertex. We are currently exploring this.

Some may seek an interpretation of the gap equation’s distinct solutions. Here, again, the \(\sigma\)-model analogy is useful. Consideration reveals that the gap equation’s solutions are representations at an elementary level of the misaligned chiral order parameter that is the focus in discussions of disordered chiral condensates, many consequences of which are reviewed in Ref. [31]. We are currently examining others that may be equally useful; e.g., as stated above, by calculating hadron properties in the different vacua.

Equation (31) is valid for \(M_+(p^2)\) and \(M_W(p^2)\). In fact, one can make a stronger statement, while \(M_+(p^2)\), \(M_W(p^2)\) exist:

\[
M_+(p^2) \sim A_W^2 m_{cr} \quad M_-(p^2) \sim B_W^2 m_{cr}\]

This follows from asymptotic freedom, which is a feature

---

**FIG. 5:** Momentum dependence of the dressed-quark mass-function, \(M(p^2)\): upper panel – chiral limit; middle panel – \(m(\zeta_{19}) = 5\,\text{MeV}\); lower panel – \(m(\zeta_{19}) = 50\,\text{MeV}\), for which there is naturally no \(M_-(p^2)\) solution. In each panel the solid curve is \(M_+(p^2)\); the dashed curve is \(M_-(p^2)\); and the dotted curve is \(M_W(p^2)\). All results obtained with \(\omega = 0.4\,\text{GeV}\).

with this dressed-quark propagator. The critical current-quark mass depends on \(\omega\):

\[
\begin{align*}
\omega [\text{GeV}] & & 0.3 & & 0.4 & & 0.5 \\
m_{cr} [\text{MeV}] & & 71 & & 63 & & 31 \\
m_{cr}(\zeta_{19}) [\text{MeV}] & & 35 & & 31 & & 15 \\
m_{cr}(\zeta_{1}) [\text{MeV}] & & 60 & & 53 & & 26
\end{align*}
\]

where the third and fourth rows report the critical mass at the renormalisation scales described above. (NB. In most phenomenological applications \(0.3 < \omega < 0.4\) in analyses of hadron observables founded on the models that form the basis of our arguments, the \(s\)-quark RGI current-mass exceeds \(m_{cr}\).

It is noteworthy that we also find a Wigner solution when applying Eq. (10); i.e., in this case, for nonzero current-quark mass we find an analogue of \(M_W\) in Eq. (10). This suggests that the presence of the Wigner
of the RGI model and QCD. One may argue for this result as follows. On the weak-coupling domain

$$A_{\pm W}(p^2, \zeta^2) \approx 1, \quad \frac{M_{\pm W}(p^2)}{p^2 + M_{\pm W}(p^2)} \approx \frac{M_{\pm W}(p^2)}{p^2}. \quad (36)$$

Hence, the gap equation becomes a single linear integral equation for $M_{\pm W}(p^2)$. Within the domain on which the preceding steps are valid, that equation can be approximated by a linear second-order ordinary differential equation (d.e.) (e.g., Refs. 41, 42, 43, 44). The d.e. is the same for every one of the functions $M_{\pm W}(p^2)$, as is the ultraviolet boundary condition, which is determined by the current-quark mass. Thus follows Eq. (35), a result evident in Figs. 5, 6.

In general the gap equation is solved as a nonlinear integral equation. It is straightforward to obtain the $M_{\pm}(p^2)$ solutions via iteration. However, for nonzero current-quark mass the Wigner solution is harder to fix. A careful seed function for iteration must be chosen and an adaptive iterative approach employed to reach the solution. To be concrete, a Chebyshev expansion was employed for the solution functions and a Newton iteration procedure used to determine the coefficients, after the manner of Ref. 45. The seed for iteration was $A = 1$ and $B = -10 m(\zeta)$, and convergence to solution first obtained with $\omega = 0.6 \text{ GeV}^3$. With $\omega = 0.4 \text{ GeV}$, small steps in $D$ were subsequently made to reach the value in Eq. (30). All solutions are illustrated in Fig. 5 and, for clarity and emphasis, we compare $M_{-}(p^2)$ and $M_{W}(p^2)$ in Fig. 6.

In the context of the d.e. argument presented above, we add that the model gap equation has often been approximated by a single second-order d.e., which is nonlinear in $M(p^2)$ for infrared momenta but linear in the ultraviolet [41, 42, 43, 44]. As we remarked, the ultraviolet boundary condition for all solutions is still fixed by the current-quark mass and the solutions agree. However, as apparent in Fig. 4, $A_W \neq 1$ on the domain of infrared momenta. Hence, while a single d.e. remains a valid approximation for $M_{-}(p^2)$, that is not the case for the Wigner solution. This emphasises that the differences between $M_{+}(p^2)$, $M_{-}(p^2)$ and $M_{W}(p^2)$ are a primarily infrared effect; i.e., nonperturbative in the coupling.

Using Eq. (35) and the subsequent discussion it becomes clear that the gauge-invariant quantity

$$\tilde{\sigma}(m(\zeta)) := \lim_{\Lambda \rightarrow \infty} Z_A(\zeta^2, \Lambda^2) N_v \tr D \int_q^\Lambda \tilde{S}_m^{m(\zeta)}(q, \zeta), \quad (37)$$

where

$$\tilde{S}_m^{m(\zeta)}(q, \zeta) = \frac{1}{2} \left[ S_+^{m(\zeta)}(q, \zeta) - S_-^{m(\zeta)}(q, \zeta) \right], \quad (38)$$

is a current-quark-mass-dependent quark condensate that is well-defined, finite and unambiguous, and has a perturbative expansion in $\tilde{m}$ on a bounded interval. In addition, $\tilde{\sigma}(m(\zeta))$ evolves under the renormalisation group in precisely the same manner as the chiral-limit vacuum quark condensate and is identical to the vacuum quark condensate in the chiral limit. Equation (37) is unique in possessing all these properties.

For additional clarity we remark that for $\tilde{m} \neq 0$ there is no term in a perturbative expansion around the chiral limit of the integrand in Eq. (37) that is odd in $\tilde{m}$. Now, since a weak-coupling evaluation of the scalar piece of the quark propagator yields an expression that is odd
The DCSB solutions are distinguished by their value at current-quark mass. The behaviour of $\hat{\sigma}(m(\zeta))$ obtained with the RGI model employed herein is depicted in Fig. 4. As we saw in connection with Fig. 4 here, too, the essentially dynamical component of chiral symmetry breaking decreases with increasing current-quark mass, following the trend predicted by the constituent-quark $\sigma$-term (Ref. [22], Sec. 5.2.2).

At this point we can further amplify our interpretation of $\hat{m}_{cr}$. A basic ingredient of chiral perturbation theory is the quark condensate because it introduces the mass-scale of DCSB. If the evolution with current-quark mass of this quantity about its DCSB chiral-limit value cannot be evaluated perturbatively then the expansion in $\hat{m}$ around $\hat{m} = 0$ has broken down. The pseudoscalar-meson-loop contribution to this evolution is a long-range piece of the vacuum response. Now, with Eq. (37), we can evaluate a short-range piece. While an expansion of both $M_-$ and $M_+$ in $\hat{m}$ exists, then so does a perturbative expansion of the order parameter $\hat{\sigma}$. However, $\hat{\sigma}$ has no such expansion for $\hat{m} > \hat{m}_{cr}$. A chiral expansion is invalid if either the long-range or short-range contribution fails but it is likely that they are linked.

We stress that a straightforward definition of a massive-quark condensate via the trace of a $\hat{m} \neq 0$ dressed-quark propagator is not useful because it gives a quantity that is quadratically divergent and therefore very difficult to define unambiguously. The same weakness afflicts the quantity

$$\hat{\sigma}(m(\zeta), \Lambda) = Z_4(\zeta^2, \Lambda^2 N_c) \text{tr} \int_q \hat{S}^{m(\zeta)}(q, \zeta),$$  \hspace{1cm} (39)

where

$$\hat{S}^{m(\zeta)}(q, \zeta) = \frac{1}{2} \left[ S_+^{m(\zeta)}(q, \zeta) + S_-^{m(\zeta)}(q, \zeta) \right].$$  \hspace{1cm} (40)

The discussion in Refs. [46-47] provides a context for Eqs. (37) - (40), and a connection between our reasoning and that used in other frameworks to calculate the quark condensate.

V. SUMMARY

On a bounded interval of current-quark mass, $D(\hat{m}) = \{\hat{m} \mid 0 \leq \hat{m} < \hat{m}_{cr}\}$, realistic models of QCD’s gap equation can simultaneously admit two inequivalent dynamical chiral symmetry breaking (DCSB) solutions for the dressed-quark mass-function, $M_+(p^2)$, and a solution that is unambiguously connected with the realisation of chiral symmetry in the Wigner mode, $M_W(p^2)$. The DCSB solutions are distinguished by their value at the origin: $M_+(p^2 = 0) > 0$ and $M_-(p^2 = 0) < 0$. In the ultraviolet all three solutions coincide with the running current-quark mass.

The pointwise values of all solutions evolve continuously with current-quark mass within $D(\hat{m})$. However, things change at the upper boundary. The $M_W$ solution, whose chiral limit value is perturbative in the coupling, becomes identical to the essentially nonperturbative solution $M_-$ that is actually characteristic of DCSB. Moreover, both disappear for $\hat{m} > \hat{m}_{cr}$, a domain whereupon the current-quark mass is large enough to completely destabilise these solutions. Only the positive $M_+$ solution exists on this domain. Furthermore, we provided evidence that the upper boundary of $D(\hat{m})$ also defines the radius of convergence for an expansion of $M_+$ in current-quark mass around its DCSB chiral-limit form.

Thus one has the coalescing of two qualitatively distinct solutions at $\hat{m}_{cr}$, the persistence of only one essentially nonperturbative solution for $\hat{m} > \hat{m}_{cr}$ plus the breakdown of a chiral expansion for this solution, and the simultaneous loss of a well-defined mass-dependent quark condensate. This behaviour supports an interpretation of $\hat{m}_{cr}$ as the upper bound on the domain within which a perturbative expansion of physical quantities in the current-quark mass around their chiral-limit values can uniformly be valid. In a phenomenologically efficacious renormalisation-group-improved rainbow-ladder truncation of QCD’s Dyson-Schwinger equations, the critical current-quark mass corresponds to a mass $m_{0\pi} \sim 0.45 \text{ GeV}$ ($m_{0\pi}^2 \sim 0.20 \text{ GeV}^2$) for a pseudoscalar meson constituted of equal mass-current-quarks [48]. NB. Irrespective of the current-mass of the other constituent, a meson containing one current-quark whose mass exceeds $\hat{m}_{cr}$ is never within the domain of uniform convergence.

A value of similar magnitude was deduced in Refs. [49-50] as the scale below which accuracy may be expected from the approximation of observables through a perturbative expansion in pion-like pseudoscalar-meson mass. This scale also marks the boundary below which observables should exhibit that curvature as a function of pion-like pseudoscalar-meson mass which is characteristic of chiral effective theories.
