Received September 24, 2015; Accepted October 30, 2015; Published December 21, 2015

We propose a new mechanism to solve the fine-tuning problem. We start from a multi-local action $S = \sum_i c_i S_i + \sum_{i,j} c_{i,j} S_i S_j + \sum_{i,j,k} c_{i,j,k} S_i S_j S_k + \cdots$, where the $S_i$'s are ordinary local actions. Then, the partition function of this system is given by $Z = \int d\vec{\lambda} f(\vec{\lambda})(\mathcal{T} \exp (-i \int_0^{+\infty} dt \hat{H}(\vec{\lambda} ; a_{d}(t)))|i\rangle$, where $\vec{\lambda}$ represents the parameters of the system whose Hamiltonian is given by $\hat{H}(\vec{\lambda} ; a_{d}(t))$, $a_{d}(t)$ is the radius of the universe determined by the Friedman equation, and $f(\vec{\lambda})$, which is determined by $S$, is a smooth function of $\vec{\lambda}$. If a value of $\vec{\lambda}_0$, $\vec{\lambda}_0$, dominates in the integral, we can interpret that the parameters are dynamically tuned to $\vec{\lambda}_0$. We show that this indeed happens in some realistic systems. In particular, we consider the strong CP problem, the multiple point criticality principle, and the cosmological constant problem. It is interesting that these different phenomena can be explained by one mechanism.

1. Introduction and general idea

Since the discovery of the Higgs particle [1,2], it has become more and more important to consider the fine-tuning problem [3–5]. The natural and conservative approach is to seek solutions in the context of ordinary local field theory. However, even if such theory can solve an individual problem such as the quadratic divergence of the Higgs mass, it seems difficult to answer all the problems simultaneously. Therefore, it is necessary to consider a new framework or principle beyond ordinary local field theory. There are many interesting proposals such as asymptotic safety [6], hidden duality and symmetry [7–9], classical conformality [10–15], the multiple point criticality principle (MPP) [16–33], and the maximum entropy principle [34–38].

Among them, Coleman’s theory on baby universes and the multiverse [39] seems promising. Although Coleman’s first work explains the smallness of the cosmological constant (CC), its validity is unclear because it is based on Euclidean gravity. Therefore, a Lorentzian version is inevitably needed to give reliable predictions. In Refs. [34–37], such improvements are actually done. They are essentially based on a multi-local action and the existence of the multiverse. The former is relatively natural because it arises if we take the topology change into account [39–42]. On the other hand, the idea of the multiverse is slightly uncommon because there is no evidence so far that we live in the multiverse. Therefore, it is meaningful to consider whether we can solve the fine-tuning
problem without relying on the existence of the multiverse. The purpose of this paper is to give a new framework to solve the fine-tuning problem based on a multi-local action.

We consider the partition function of the multi-local action,

\[ S_M = \sum_i c_i S_i + \sum_{i,j} c_{i,j} S_i S_j + \sum_{i,j,k} c_{i,j,k} S_i S_j S_k + \cdots, \]  

(1)

where

\[ S_i = \int_0^\infty dt \int d^3x \mathcal{O}_i(t, x) \]  

(2)

is an ordinary local action, and the \( c_i \)'s, \( c_{i,j} \)'s, ... are constants. Here, we have assumed that the universe is created at \( t = 0 \), and evolves to \( t = \infty \). Then, Eq. (1) is obtained after summing up the wormholes. See Fig. 1 for an example. Thus, by expressing \( \exp(iS_M) \) as a Fourier transform

\[ \exp(iS_M) = \int d\vec{\lambda} f(\vec{\lambda}) \exp\left(i \sum_i \lambda_i S_i\right), \]  

(3)

we can write the partition function of the system as follows:

\[ Z = \int_{t=0}^{t=\infty} D\phi \exp(iS_M) \psi_f^* \psi_i \]

\[ = \int d\vec{\lambda} f(\vec{\lambda}) \int_{t=0}^{t=\infty} D\phi \exp\left(i \sum_i \lambda_i S_i\right) \psi_f^* \psi_i \]

\[ = \int d\vec{\lambda} f(\vec{\lambda}) |f| T \exp\left(-i \int_0^{+\infty} dt \dot{H}(\vec{\lambda}; a_{cl}(t))\right) |i\rangle, \]  

(4)

where \( a_{cl}(t) \) is the radius of the universe determined by the Friedman equation, \( \psi_i \) and \( \psi_f \) represent initial and final states which are independent of \( \vec{\lambda} \), and we have assumed that the universe eternally expands like our universe.\(^1\) If there is a point \( \vec{\lambda}_0 \) that strongly dominates in the integral of Eq. (4), the observer in the universe finds that the parameters are fixed at \( \vec{\lambda}_0 \). In particular, Eq. (4) is equivalent to

\[ Z \sim f(\vec{\lambda}_0) |f| T \exp\left(-i \int_0^{+\infty} dt \dot{H}(\vec{\lambda}_0; a_{cl}(t))\right) |i\rangle. \]  

(5)

At first glance, it seems difficult to evaluate \( Z \) because it involves the total history of the universe. However, in almost all the time, the universe is sufficiently expanded, and its energy density is very close to that of the vacuum. More concretely, we have

\[ T \exp\left(-i \int_0^{+\infty} dt \dot{H}(\vec{\lambda}; a_{cl}(t))\right) |i\rangle \sim \exp\left(-i \epsilon(\vec{\lambda}) \int_{t^*}^{+\infty} dt V_3(a_{cl}(t))\right) |\psi(t^*; \vec{\lambda})\rangle, \]  

(6)

where

\[ |\psi(t; \vec{\lambda})\rangle = T \exp\left(-i \int_0^t dt' \dot{H}(\vec{\lambda}; a_{cl}(t'))\right) |i\rangle, \]  

(7)

\( V_3(a_{cl}(t)) \) is the space volume, \( \epsilon(\vec{\lambda}) \) is the vacuum energy density, and \( t^* \) is a time such that the energy density of the state \( |\psi(t; \vec{\lambda})\rangle \) is sufficiently close to \( \epsilon(\vec{\lambda}) \). By substituting Eq. (6) in Eq. (4),

\(^1\) Here, for simplicity, we have assumed that \( a_{cl}(t) \) is already given. See Sect. 5 for a more concrete argument.
we obtain
\[ Z \sim \int d\lambda f(\lambda) \exp \left( -i \varepsilon(\lambda) \int_{t^*}^{+\infty} dt V_3(a_{cl}(t)) \right) \left\{ f | \psi(t^*; \lambda) \rangle \right. \] \[ \left. \langle \lambda | \right. \] \[ = \int d\lambda \langle \lambda | \lambda \rangle \langle \lambda | \right. \] \[ \left. \lambda \right. \] \[ = \sum_i \left( a_i + a_i^\dagger \right) S_i. \] (8)

As we will see in the following discussion, we can find \( \lambda_0 \) from Eq. (8) in some phenomenologically

interesting systems.

We can also repeat the above argument from the point of view of Coleman's baby universes as follows. As discussed in [39,40], instead of using the multi-local action, the wormhole effect can be expressed by introducing operators \( \hat{a}_i \) and \( \hat{a}_i^\dagger \) that describe the creation and annihilation of a baby

universe. Namely, the action of the universe with baby universes is given by

\[ S_C = \sum_i \left( \hat{a}_i + \hat{a}_i^\dagger \right) S_i. \] (9)

See the right figure in Fig. 1 for an example. Because the \( \hat{a}_i + \hat{a}_i^\dagger \)'s are conserved quantities, for each

set of their eigenvalues, Eq. (9) is an ordinary local action for the universe. Therefore, we can develop

the quantum theory for the total system consisting of the universe and baby universes:

\[ \hat{H}_{\text{tot}} = \int d\lambda \hat{\lambda} \langle \lambda | \hat{\lambda} | \rangle \otimes \hat{H}(\lambda; a_{cl}(t)). \] (10)

Here, \( \{|\lambda\rangle\} \) is the complete set of the Fock space of the baby universes:

\[ 1 = \int d\lambda \langle \lambda | \hat{\lambda} \rangle \hat{\lambda} | \rangle \otimes \hat{H}(\lambda; a_{cl}(t)). \] (11)

and \( \hat{H}(\lambda; a_{cl}(t)) \) is the Hamiltonian for the universe that corresponds to the action \( \sum_i \lambda_i S_i \). Then,

for the initial state \( |i\rangle = |i\rangle_{\text{baby}} \otimes |i\rangle_{\text{universe}} \), the wave function at \( t \) is given by

\[ e^{-i\hat{H}_{\text{tot}}t} |i\rangle = \int d\lambda \hat{\lambda} \langle \lambda | \hat{\lambda} |i\rangle_{\text{baby}} \otimes T \exp \left( -i \int_0^t dt' \hat{H}(\lambda; a_{cl}(t')) \right) |i\rangle_{\text{universe}}. \] (12)

Thus, by considering the \( t \to +\infty \) limit, and multiplying a final state \( \langle f | := \text{baby} \langle f | \otimes \text{universe} \langle f | \) by Eq. (12), we actually obtain Eq. (4) where

\[ f(\lambda) = \text{baby} \langle f | \hat{\lambda} \rangle \langle \lambda |i\rangle_{\text{baby}}. \] (13)
This is the derivation of Eq. (4) from the point of view of Coleman’s baby universes. Note that the weight function \( f(\vec{\lambda}) \) is not important in the following discussion because we will consider the general consequences which do not depend on the detail of \( f(\vec{\lambda}) \) as long as it is a smooth function. In the following, we do not consider such a special case that \( |i_{\text{baby}} \rangle \) or \( |f_{\text{baby}} \rangle \) is \( |\vec{\lambda}' \rangle \).

Because the above point of view is rather uncommon, let us see a simple example here:

\[
S = \int_{-\infty}^{+\infty} dt \left( \frac{m}{2} \dot{x}^2 - \frac{m\omega_0^2}{2} x^2 \right) + \frac{m^2 \kappa}{4} \int_{-\infty}^{+\infty} dt x^2 \int_{-\infty}^{+\infty} dt' x^2
\]

\[
:= S_0 + \kappa S_H^2,
\]

(14)

where

\[
S_0 = \int_{-\infty}^{+\infty} dt \left( \frac{m}{2} \dot{x}^2 - \frac{m\omega_0^2}{2} x^2 \right), \quad S_H = \frac{m}{4} \int_{-\infty}^{+\infty} dt x^2.
\]

(15)

This is a harmonic oscillator having an additional bi-local action \( S_H^2 \). By using a Lagrangian multiplier \( \lambda_1 \), the path integral of this system can be rewritten as follows:

\[
Z = \int \mathcal{D}x \exp \left( i S_0 + i \kappa S_H^2 \right)
\]

\[
= \sqrt{-i\kappa/\pi} \int d\lambda_1 e^{-i\lambda_1^2} \int \mathcal{D}x \exp \left( i S_0 + 2i\kappa \lambda_1 S_H \right)
\]

\[
:= \int d\lambda f(\lambda) \int \mathcal{D}x e^{i\tilde{S}(\lambda)},
\]

(16)

where

\[
\tilde{S}(\lambda) = \int_{-\infty}^{+\infty} dt \left( \frac{m}{2} \dot{x}^2 - \frac{m\lambda}{2} x^2 \right), \quad f(\lambda) := \sqrt{-i/\kappa\pi} \times e^{-i \left( \frac{\omega_0^2 - \lambda}{\kappa} \right)^2}.
\]

(17)

Here, in the last line in Eq. (16), we have changed the variable:

\[
\lambda := \omega_0^2 - \kappa \lambda_1.
\]

(18)

One can see that Eq. (16) actually has the form of Eq. (4). However, \( \lambda \) is not fixed to any special value because the integrand in Eq. (16) is a regular function of \( \lambda \) in this case. On the other hand, as we will see, if we consider systems with infinite degrees of freedom, \( \vec{\lambda} \) is indeed fixed to a special value in several cases.

In the following sections, we study a few examples which show that the above argument is not an armchair theory. In particular, we consider the strong CP problem, the MPP, and the cosmological constant problem (CCP). The MPP is a proposal to solve the fine-tuning problem, which claims that, when a field theory has two vacua, the parameters are fixed so that they become degenerate. In regard to the CCP, we will see that the CC is nearly fixed to zero by generalizing Eq. (4) to the Wheeler–DeWitt wave function. In order to explain the positive small CC, we will give an argument based on the existence of the multiverse.

This paper is organized as follows. In Sect. 2, we give a few important mathematical preliminaries. In Sect. 3, we discuss the strong CP problem. In Sect. 4, we derive the MPP from Eq. (4). In Sect. 5, we consider the CCP by generalizing Eq. (4) to the Wheeler–DeWitt wave function. In Sect. 6, we give a summary and discussion.
2. Mathematical preliminaries

In this section, we consider the singular behavior of $e^{ikg(\lambda)}$ in the $k \to \infty$ limit, which plays a crucial role in the following discussion.

If $g(\lambda)$ is smooth, and has a stationary point $\lambda_0$, we obtain

$$e^{ikg(\lambda)} \sim \sqrt{\frac{2\pi}{ikg''(\lambda)}} e^{ikg(\lambda_0)} \delta(\lambda - \lambda_0), \quad (19)$$

by using the saddle point approximation. Note that the right-hand side is suppressed by the factor $\sqrt{k}$.

If $g(\lambda)$ is smooth and monotonic in the $\lambda > 0$ region, and $g'(0) \neq 0$, we have

$$e^{ikg(\lambda)} \theta(\lambda) \sim \frac{i}{k} \left( \frac{dg}{d\lambda} \right)^{-1} e^{ikg(0)} \delta(\lambda), \quad (20)$$

where $\theta(\lambda)$ is a step function. The proof is as follows. By multiplying a test function $F(\lambda)$ with finite support to $e^{ikg(\lambda)}$, and integrating from 0 to $\infty$, we obtain

$$\int_0^\infty d\lambda e^{ikg(\lambda)} F(\lambda) = \left. \left[ \frac{e^{ikg(\lambda)}}{ik} \left( \frac{dg}{d\lambda} \right)^{-1} F(\lambda(\lambda)) \right] \right|_{g(0)}^{\infty} + \mathcal{O}\left( \frac{1}{k^2} \right)$$

$$= \left. \frac{i}{k} \left( \frac{dg}{d\lambda} \right)^{-1} e^{ikg(0)} F(\lambda) \right|_{\lambda=0} + \mathcal{O}\left( \frac{1}{k^2} \right). \quad (21)$$

Thus, one can see that Eq. (20) holds in the $k \to \infty$ limit. Note that the right-hand side is proportional to $1/k$, which is small compared with Eq. (19).

Similarly, we can obtain the following equation for $g(\lambda)$ that is smooth and monotonic in each of the regions, $\lambda > \lambda_0$ and $\lambda < \lambda_0$:

$$e^{ikg(\lambda)} \sim \frac{i}{k} \left[ e^{ikg(\lambda)} \left( \frac{dg}{d\lambda} \right)^{-1} \right]_{\lambda_0+} - e^{ikg(\lambda)} \left( \frac{dg}{d\lambda} \right)^{-1} \delta(\lambda - \lambda_0). \quad (22)$$

Note that the right-hand side is non-zero only when $g(\lambda)$ is not smooth at $\lambda_0$. We will call such a point a $\lambda_0$ non-analytic point.

3. Strong CP problem

In the QCD Lagrangian, there exists a CP-violating topological term

$$S_{\theta} := \frac{\theta}{16\pi^2} \int d^4 x F_{\mu\nu}^{\alpha} \tilde{F}^{\alpha\mu\nu}. \quad (23)$$

Experimentally, there is a strong upper bound on $\theta$ [5,43],

$$\theta < 10^{-9}, \quad (24)$$

which is unnaturally small. This is the so-called “strong CP problem.” We can naturally solve this problem as follows.
From the general argument of Sect. 1, the partition function is given by
\[ Z \sim \int_0^{2\pi} d\theta f(\theta) \exp \left( -i\varepsilon(\theta) \int_{t^*}^{+\infty} dt V_2(a(t)) \right) \langle f|\psi(t^*; \theta) \rangle \]
\[ = \int_0^{2\pi} d\theta f(\theta) \exp (-i\varepsilon(\theta)V_4) \langle f|\psi(t^*; \theta) \rangle, \]  \tag{25}
where
\[ \varepsilon(\theta) \sim \Lambda_{\text{QCD}}^4 \cos \theta \]  \tag{26}
is the energy density of the \( \theta \) vacuum (see [44] for an example), and \( V_4 \) is the volume of the space time. If we consider such a final state with a finite winding number,\(^2\) using Eq. (19), we obtain\(^3\)
\[ \exp (-i\varepsilon(\theta)V_4) \sim \sqrt{2\pi i V_4 \Lambda_{\text{QCD}}^4} \left( e^{-i\varepsilon(0)V_4} \delta(\theta) + e^{-i\varepsilon(\pi)V_4} \delta(\theta - \pi) \right). \]  \tag{27}
By substituting this into Eq. (25), the partition function becomes
\[ Z \sim \sqrt{\frac{1}{V_4 \Lambda_{\text{QCD}}^4}} \left[ f(0)e^{-i\varepsilon(0)V_4} \langle f|\psi(t^*; 0) \rangle + f(\pi)e^{-i\varepsilon(\pi)V_4} \langle f|\psi(t^*; \pi) \rangle \right]. \]  \tag{28}
This shows that the partition function is strongly dominated by \( \theta = 0 \) and \( \theta = \pi \) worlds, as in the many-world interpretation.

4. The multiple point criticality principle

In this section, we derive the MPP by assuming that the potential \( V(\phi, \lambda) \) of a scalar field \( \phi \) has two minima at \( \phi_1(\lambda) \) and \( \phi_2(\lambda) \), where we take \( \phi_1(\lambda) < \phi_2(\lambda) \). Here, \( \lambda \) is one of the coupling constants of the theory. We assume that two minima become degenerate when \( \lambda \) is equal to zero, and that the signature of \( \lambda \) is chosen as
\[ V(\phi_1(\lambda), \lambda) < V(\phi_2(\lambda), \lambda) \quad \text{for} \ \lambda > 0, \]
\[ V(\phi_1(\lambda), \lambda) > V(\phi_2(\lambda), \lambda) \quad \text{for} \ \lambda < 0. \]  \tag{29}
See Fig. 2 for an example. Then, the true vacuum expectation value \( \phi_{\text{vac}}(\lambda) \) and the vacuum energy density \( \varepsilon(\lambda) \) are given by
\[ \phi_{\text{vac}}(\lambda) = \begin{cases} \phi_2(\lambda) & \text{for} \ \lambda < 0, \\ \phi_1(\lambda) & \text{for} \ \lambda > 0, \end{cases} \]
\[ \varepsilon(\lambda) = \begin{cases} V(\phi_2(\lambda)) & \text{for} \ \lambda < 0, \\ V(\phi_1(\lambda)) & \text{for} \ \lambda > 0. \end{cases} \]  \tag{30}
According to Eq. (4), the partition function is given by
\[ Z = \int d\lambda f(\lambda) \exp (-i\varepsilon(\lambda)V_4) \langle f|\psi(t^*; \lambda) \rangle. \]  \tag{31}
We assume that \( V(\phi_1(\lambda)) \) and \( V(\phi_2(\lambda)) \) are monotonic functions of \( \lambda \) in \( \lambda > 0 \) and \( \lambda < 0 \) respectively, and that their derivatives are not equal at \( \lambda = 0 \). Because, for generic \( |f \rangle \), \( \langle f|\psi(t^*; \lambda) \rangle \) has no

\(^2\) If \( |f \rangle \) is the \( n \) vacuum \( |n \rangle \) with a large value of \( n \sim \Lambda_{\text{QCD}}^4 V_4 \), the exponent of the integrand in Eq. (25) becomes stationary at the point where \( \sin \theta \sim n / (\Lambda_{\text{QCD}}^4 V_4) \).

\(^3\) If \( k \) is finite in Eq. (19), we have a function of width \( 1/\sqrt{k^{\prime}(\lambda)} \) instead of the delta function. Then, the width \( \Delta \theta \) is given by \( \sqrt{1/ (V_4 \Lambda_{\text{QCD}}^4)} \sim 10^{-80} / \left( \sqrt{V_4 H_0^2} \right) \), where \( H_0 \) the present Hubble constant.
Singularity at $\lambda = 0$, we can use Eq. (22):

$$e^{-i\varepsilon(\lambda)}V_4 \sim -\frac{i}{V_4} \left[ \left( \frac{V(\phi_1(\lambda))}{d\lambda} \right)^{-1} \bigg|_{0^+} - \left( \frac{V(\phi_2(\lambda))}{d\lambda} \right)^{-1} \bigg|_{0^-} \right] \delta(\lambda). \quad (32)$$

By substituting this into Eq. (31), we obtain

$$Z \sim f(0) \times e^{-i\varepsilon(0)}V_4 \langle f | \psi(t^*); 0 \rangle. \quad (33)$$

Thus we have derived the MPP in the context of the multi-local action.

5. Generalization to Wheeler–DeWitt wave function

In this section, we consider the generalization of Eq. (4) to the Wheeler–DeWitt wave function and the fine-tuning of the physical CC $\Lambda$. Unfortunately, it is not easy to consider the negative region $\Lambda < 0$ because we do not know what happens after the Big Crunch. On the other hand, in the positive region $\Lambda > 0$, we can consider the Wheeler–DeWitt wave function for the entire region of the radius of the universe, and examine which value of $\tilde{\lambda}$ dominates. Therefore, in the following, we take only the region $\Lambda > 0$ into account in the path integral.

Then the generalization of Eq. (4) to the Wheeler–DeWitt wave function is given by

$$Z_{WD} = \int d\Lambda_B \int d\tilde{\lambda} \ f(\Lambda_B, \tilde{\lambda}) \theta(\Lambda) \times \int_0^\infty dT \left( f_a \otimes \langle f_{MR} | e^{-i(\hat{H}_G(\Lambda_B) + \hat{H}_{MR}(\tilde{\lambda}; \hat{a}))}T | \varepsilon \rangle \otimes | i_{MR} \rangle \right), \quad (34)$$

where $\hat{H}_G(\Lambda_B) := -\hat{p}_a^2 / \left( 2\hat{a}M_{pl}^2 \right) + \Lambda_B$ is the Hamiltonian for the radius of the universe $a$ with the bare CC $\Lambda_B$ [36], $\hat{H}_{MR}(\tilde{\lambda}; \hat{a})$ represents the other degrees of freedom, that is, the matter and radiation including gravitons, and $| \varepsilon \rangle \otimes | i_{MR} \rangle (| f_a \rangle \otimes | f_{MR} \rangle)$ is an initial (a final) state of the universe. (We have assumed that the initial universe has the radius $a = \epsilon$.) The integration over $T$ comes from the path integral for the lapse function. In the following discussion, we assume $| f_a \rangle = | a_\infty \rangle$ where $a_\infty$ represents the large radius of the universe. Before considering the CCP, we first re-derive the results of the previous sections from Eq. (34).
5.1. Fixing other parameters than the cosmological constant

Equation (34) differs from Eq. (4) in that it contains the integration over the time \( T \). However, the results in the previous sections can also be obtained from Eq. (34) because, for a fixed value of \( a \), the \( T \) integral is dominated by \( T_a \) at which the radius of the universe becomes \( a \). More concretely, we have

\[
\int_0^\infty dT \left( a \int f_{MR} \left| e^{-i(\hat{H}_{CB} + \hat{H}_{MR}(\vec{\lambda} ; \hat{a}))T} \right| \right) = \int_0^\infty dT \left( a \int f_{MR} \left| \exp \left( -i \int_0^{T_a} dt \hat{H}_{MR}(\vec{\lambda} ; a_{cl}(t)) \right) \right| \right)
\]

where we have omitted the integrations over \( \Lambda_B \) and \( \vec{\lambda} \) for simplicity. Here, \( a_{cl}(t) \) satisfies the following Friedman equation and boundary condition:

\[
H^2 := \left( \frac{a_{cl}}{a_{cl}} \right)^2 = \frac{1}{3M^2_{pl}} \left( \Lambda_B + \frac{\langle \psi_{MR}(T) | \hat{H}_{MR}(\vec{\lambda} ; a_{cl}(T)) | \psi_{MR}(T) \rangle}{V_3(a_{cl}(T))} \right), \quad a_{cl}(0) = \epsilon,
\]

where \( V_3(a_{cl}(T)) \) is the volume of the space. We can understand Eq. (35) within the Born–Oppenheimer approximation [45] by assuming that the expansion rate \( H \) is very small compared with the energy scale of the other degrees of freedom. See Appendix A for the details.

Using Eq. (35), we can re-derive the results of the previous sections. For a sufficiently large value of \( a \), we can replace the Hamiltonian \( \hat{H}_{MR}(\vec{\lambda} ; a_{cl}(T_a)) \) by the vacuum energy \( E_0(\vec{\lambda} ; a_{cl}(T_a)) = \epsilon(\vec{\lambda})V_3(a_{cl}(T_a)) \), as in Eq. (8). Therefore, the right-hand side of Eq. (35) becomes

\[
\exp \left( -i \int_0^{T_a} dt \hat{H}_{MR}(\vec{\lambda} , a_{cl}(t)) \right) |i_{MR}\rangle \sim \exp \left( -i \epsilon(\vec{\lambda}) \int_0^{T_a} dt V_3(a_{cl}(t)) \right) |\psi_{MR}(t^*)\rangle,
\]

where \( t^* \) is a time such that the energy density of the state \( |\psi_{MR}(t^*)\rangle \) is sufficiently closed to that of the vacuum. Then, Eq. (34) can be written as

\[
\int d\Lambda_B \int d\vec{\lambda} f(\Lambda_B , \vec{\lambda}) \theta(\Lambda) \exp \left( -i \epsilon(\vec{\lambda}) \int_0^{T_a} dt V_3(a_{cl}(t)) \right) \langle f_{MR} | \psi_{MR}(t^*) \rangle.
\]

Thus, by repeating the same argument, we can re-derive the results of the previous sections.

5.2. Solving the cosmological constant problem

In order to fix \( \Lambda \), it is sufficient to consider the effective action for the radius \( a \) because only the vacuum energy is relevant:

\[
Z = \int_0^\infty dT \int_0^\infty d\Lambda f(\Lambda) \left( a_{\infty} \right) e^{-i\hat{H}(\Lambda)T} \epsilon, \tag{39}
\]

where the effective Hamiltonian \( \hat{H}(\Lambda) \) is

\[
\hat{H}(\Lambda) = -\frac{\hat{p}_a^2}{2\hat{a}M^2_{pl}} + \frac{\hat{a}^3 \rho(\hat{a})}{6}, \quad \rho(\hat{a}) = \Lambda + \rho_{MR}(\hat{a}). \tag{40}
\]

Here, \( \rho_{MR}(\hat{a}) \) stands for the energy density of the matter and radiation including gravitons. One can see that \(-\hat{a}^4 \rho(\hat{a})\) plays the role of a potential of the radius of the universe. By inserting the
complete set

\[ 1 = \int_{-\infty}^{+\infty} dE |E; \Lambda \rangle \langle E; \Lambda|, \quad \hat{H}(\Lambda)|E; \Lambda\rangle = E|E; \Lambda\rangle \]  

(41)

into Eq. (39), we obtain

\[ Z = \int_0^\infty d\Lambda f(\Lambda) \int_0^\infty dt \int_{-\infty}^{+\infty} dE \exp\left( -iEt \right) |E; \Lambda\rangle \langle E; \Lambda|e \]

\[ = \int_0^\infty d\Lambda f(\Lambda) \left( \pi \langle a_\infty|0; \Lambda \rangle \langle 0; \Lambda|e \rangle + PV \int_{-\infty}^{+\infty} dE \langle a_\infty|E; \Lambda \rangle \langle E; \Lambda|e \rangle \right), \]  

(42)

where \( |0; \Lambda\rangle \) is the zero-energy eigenstate, and \( PV \) represents the principal value. Here, we have used the following identity: \(^4\)

\[ \lim_{t \to +\infty} e^{-iEt} \frac{1}{-iE} = \pi \delta(E) + PV \frac{1}{E}. \]  

(43)

The second term in Eq. (42) comes from the fact that we have chosen \( t = 0 \) as the beginning of the universe. However, because the universe is well described classically by the Friedman equation, we expect that only the small region around \( E = 0 \) is relevant in this integral. In Appendix B, we actually check this by using the WKB (Wentzel–Kramers–Brillouin) approximation. As a result, Eq. (42) can be approximated by

\[ Z \sim \int_0^\infty d\Lambda f(\Lambda) \langle a_\infty|0; \Lambda \rangle \langle 0; \Lambda|e \rangle. \]  

(44)

Let us now evaluate \( \langle a|0; \Lambda \rangle \) by using the WKB approximation. The Wheeler–DeWitt wave function is given by [36]

\[ \langle a|0; \Lambda \rangle = M_{pl} \sqrt{\frac{a}{p_{cl}}} \exp \left( i \int_a^a da' p_{cl}(a') \right), \quad p_{cl}(a) := M_{pl} a^2 \sqrt{\frac{\rho(a)}{3}}, \]  

(45)

where \( p_{cl}(a) \) is the classical momentum. For simplicity, we consider a matter-dominated universe,

\[ \rho(a) = \Lambda + \frac{M}{a^3} := \Lambda + \rho_M(a), \]  

(46)

where \( M \) is the total energy of the matter. Then, we can evaluate the exponent in Eq. (45):

\[ \int_a^a da' p_{cl}(a') = \frac{M_{pl}}{3^2} \left( a^3 \sqrt{\rho(a)} - a^3_M \sqrt{\rho(a_M)} + \frac{M}{\sqrt{\Lambda}} \log \left[ \frac{a^3_M(\Lambda + \sqrt{\Lambda} \rho(a_M))}{a^3_M(\Lambda + \sqrt{\Lambda} \rho(a_M))} \right] \right) \]

\[ := \frac{M_{pl}}{3^2} g(\Lambda, a), \]  

(47)

---

\(^4\) The derivation is as follows: We can neglect \( e^{-iEt} \) by introducing the adiabatic factor \( E \to E - i\epsilon \). Thus, by multiplying a smooth test function \( F(E) \) with finite support to the left-hand side, and integrating over \( E \), we have

\[ \int_{-\infty}^\infty dE \frac{-1}{E} F(E) = \pi F(i\epsilon) - PV \int_{-\infty}^\infty dE \frac{F(E)}{E - i\epsilon}. \]

Therefore, in the \( \epsilon \to 0 \) limit, we obtain Eq. (43). Here, note that, if we also include the negative region in the time integral, we obtain the delta function \( 2\pi \delta(E) \) instead of Eq. (43). This leads to the ordinary Wheeler–DeWitt state \( |0; \Lambda\rangle \).
We have proposed a new mechanism to solve the fine-tuning problem of the universe: Assuming all the universes are copies of our universe. Equation (51) indicates a new possibility to explain the discrepancy by assuming the multiverse.

6. Summary and discussion

We have proposed a new mechanism to solve the fine-tuning problem of the universe: Assuming all the universes are copies of our universe. Equation (51) indicates a new possibility to explain the discrepancy by assuming the multiverse.
to fix the parameter $g$: it is fixed to the saddle point $g^*$ of $Z_U(g)$ even if $Z_U(g)$ itself does not have a strong peak as $\delta(g - g^*)$. $Z_U(g)$ can be expanded as

$$Z_U(g) = Z_U(g^*) + \frac{1}{2} \left. \frac{d^2 Z_U}{d g^2} \right|_{g=g^*} \delta(g - g^*)^2 + \mathcal{O}((g - g^*)^3).$$

(52)

From the path integral expression,

$$Z_U(g) = \int \mathcal{D}\phi e^{i S_g + \cdots} \times \psi_i^* \psi_i,$$

(53)

$d^2 Z_U/d g^2 \big|_{g=g^*}$ can be expressed as the expectation value of the local action $S_g$:

$$
\left. \frac{d^2 Z_U}{d g^2} \right|_{g=g^*} = - \int \mathcal{D}\phi e^{i S_g^* + \cdots} S_g^2 \times \psi_i^* \psi_i \\
:= -(\hat{S}_g^2) Z_U(g^*).
$$

(54)

Therefore, the fluctuation of $g$ around $g^*$ is given by

$$\Delta g \sim \left( \left. \frac{d^2 Z_U}{d g^2} \right|_{g=g^*} \right)^{-\frac{1}{2}} = \frac{1}{\sqrt{(\hat{S}_g^2) Z_U(g^*)}}.$$  

(55)

Typically, $(\hat{S}_g^2) \propto TV_3$ because

$$
(\hat{S}_g^2) = \int d^4 x \int d^4 y \langle \hat{O}_{g^*}(x) \hat{O}_{g^*}(y) \rangle_{\text{contract}} \\
= \int d^4 x \int d^4 y W(x - y) \\
= V_4 \int d^4 x W(x) \sim V_4 M_{pl}^4,
$$

(56)

where we have assumed that the cut-off scale is $M_{pl}$, and that $\int d^4 x W(x) \sim M_{pl}^4$ by dimensional analysis. Thus, one can see that $\Delta g$ is of order $(V_4 M_{pl}^4 Z_U(g^*))^{-\frac{1}{2}}$. This leads to the fluctuation of the vacuum energy density $\Delta \rho_0$, which is typically

$$\Delta \rho_0 \sim M_{pl}^4 \Delta g \sim \frac{M_{pl}^4}{\sqrt{V_4 M_{pl}^4 Z_U(g^*)}} \sim \frac{M_{pl}^2 H_0^2}{\sqrt{Z_U(g^*)}},$$

(57)

where we have replaced $V_4$ with $H_0^{-4}$. Thus, if $Z_U(g^*)$ is $\mathcal{O}(1)$, this fluctuation is consistent with the observed value. Although this conclusion is based on a few nontrivial assumptions, it is interesting that such a small CC can be obtained by maximizing the partition function as a function of the parameter.

In conclusion, the theory of the multi-local action is attractive and promising in solving the fine-tuning problem of the universe.

Appendix A. The Born–Oppenheimer approximation

In this appendix, we give a justification of Eq. (35) based on the Born–Oppenheimer approximation. Because the time scale of $a$ is much longer than that of the matter and radiation, the total wave function can be obtained as follows.

**Step 1:** We first solve the Schrödinger equation for the matter and radiation assuming that $a_{cl}(t)$ is a slowly changing c-number function of $t$:

$$-i \frac{\partial}{\partial t} |\psi_{MR}(t)\rangle = \hat{H}_{MR}(a_{cl}(t)) |\psi_{MR}(t)\rangle.$$ (A1)

Then, the expectation value of the energy as a function of $a$ is given:

$$E_{MR}(a, t) := \langle \psi_{MR}(t) | \hat{H}_{MR}(a) |\psi_{MR}(t)\rangle.$$ (A2)

**Step 2:** By using $E_{MR}(a, t)$, we solve the Schrödinger equation for $a$:

$$-i \frac{\partial}{\partial t} |\psi_{r}(t)\rangle = \left( \hat{H}_{G} + E_{MR}(\hat{a}) \right) |\psi_{r}(t)\rangle.$$ (A3)

Then, we identify $a_{cl}(t)$ with the expectation value of the radius,

$$a_{cl}(t) = \langle \psi_{r}(t) | \hat{a} |\psi_{r}(t)\rangle.$$ (A4)

By solving Eqs. (63)–(66) in a self-consistent manner, we obtain

$$\langle a | \otimes \langle f_{MR}| e^{-i \left( \hat{H}_{G}(\Lambda) + \hat{H}_{MR}(\hat{a} : \hat{a}) \right) t |\epsilon \rangle \otimes |i_{MR} \rangle \sim \langle a |\psi_{r}(t)\rangle \langle f_{MR}| T \left\{ \exp \left( -i \int_{0}^{t} dt' \hat{H}_{MR}(a_{cl}(t')) \right) \right\} |i_{MR} \rangle.$$ (A5)

Then, within the Born–Oppenheimer approximation, the Wheeler–DeWitt wave function is given by

$$\langle a | \otimes \langle f_{MR}| \psi \rangle = \int_{0}^{\infty} dt \langle a |\psi_{r}(t)\rangle \langle f_{MR}| T \left\{ \exp \left( -i \int_{0}^{t} dt' \hat{H}_{MR}(a_{cl}(t')) \right) \right\} |i_{MR} \rangle.$$ (A6)

Here, because $\langle a |\psi_{r}(t)\rangle$ has a peak at $a_{cl}(t)$ as a function of $a$, the $t$ integral of Eq. (A6) is dominated by $T_{a}$ such that

$$a_{cl}(T_{a}) \sim a.$$ (A7)

Thus, we obtain Eq. (35).

Appendix B. Evaluation of the principal value

In this appendix, we evaluate

$$PV \int_{-\infty}^{+\infty} \frac{dE}{E} \langle a |E; \Lambda \rangle \langle E; \Lambda |\epsilon \rangle$$ (B1)

by using the WKB approximation. The WKB solution of $\langle a |E; \Lambda \rangle$ is given by

$$\langle a |E; \Lambda \rangle = M_{pl} \sqrt{\frac{a}{p_{cl}}} \exp \left( i \int_{a}^{a'} da' p_{cl}(a') \right),$$ (B2)
where

\[ p_{cl}(a) = M_{pl}a^2 \sqrt{\frac{2}{3} \left( \frac{\rho(a)}{a^3} \right)} := M_{pl}a^2 \sqrt{\frac{\rho(a)}{3}}. \]  

(B3)

Then, for a sufficiently large value of \( a \), we have

\[
\int_{a_M}^{a} da p_{cl}(a) = \frac{M_{pl}}{3^2} \left( a^3 \sqrt{\rho(a)} - a^3 M_{pl} \sqrt{\rho(a_M)} + \frac{M - E}{\sqrt{\Lambda}} \log \left[ \frac{a^3 (\Lambda + \sqrt{\Lambda} \rho(a))}{a^3 M_{pl} \sqrt{\rho(a_M)}} \right] \right) 
\]

:= \frac{M_{pl}a^3}{3^2} g(\Lambda, E, a) \approx \frac{M_{pl}a^3}{3^2} \sqrt{\rho(a)}. \]  

(B4)

By substituting Eq. (B2) and Eq. (B4) into Eq. (B1), we obtain

\[
PV \int_{-\infty}^{\infty} dE \frac{a}{E} M_{pl} \sqrt{\frac{\rho(a)}{p_{cl}}} \exp \left( -i \frac{M_{pl}a^3}{3^2} \sqrt{\rho(a)} \right) \langle E; \Lambda | \epsilon \rangle. \]  

(B5)

By expanding the exponent around \( E = 0 \), we have

\[
M_{pl} \sqrt{\frac{a}{p_{cl}}} \exp \left( -i \frac{M_{pl}a^3}{3^2} \sqrt{\rho(a)} - i \frac{M_{pl}E}{3^2} \sqrt{\rho(a)} + O(E^2) \right) \]

= \langle a|0; \Lambda \rangle \exp \left( -i \frac{M_{pl}E}{3^2} \sqrt{\rho(a)} + O(E^2) \right). \]  

(B6)

Therefore, only the region

\[
|E| \lesssim \frac{\sqrt{\rho(a)}}{M_{pl}} \sim \frac{\sqrt{\Lambda}}{M_{pl}} \]  

(B7)

contributes to the integral.\(^5\) Therefore, it is self-consistent to show \( \Lambda = 0 \) by using only the zero-energy eigenstate \(|0\rangle\).

### Appendix C. Symmetry enhancement

In this appendix, we study a mechanism by which symmetry is enhanced. In particular, we consider a scalar field \( \phi \) with the effective potential

\[
V(\phi) = a_1 \phi + \frac{a_2}{2} \phi^2 + a_3 \phi^3 + \frac{a_4}{4} \phi^4, \]

(C1)

where \( a_4 \) is fixed to a positive value so that the system is bounded below. We can eliminate \( a_3 \phi^3 \) by shifting the field, \( \phi \rightarrow \phi + \phi_0 \), and the potential becomes

\[
V(\phi) = a_1 \phi + \frac{a_2}{2} \phi^2 + \frac{a_4}{4} \phi^4. \]  

(C2)

In Fig. C1, we show the typical shapes of \( V(\phi) \). In the following discussion, we fix \( a_2 \) and vary \( a_1 \). We denote the negative (positive) vacuum expectation value by \( \phi_1(a_1) \) (\( \phi_2(a_1) \)). According to the

\(^5\) More concretely, by substituting Eq. (B6) into Eq. (B1), and neglecting the \( E \) dependence of \( \langle E; \Lambda | \epsilon \rangle \), we obtain

\[
\langle a|0; \Lambda \rangle PV \int_{-\infty}^{a_M} dE \frac{E}{M_{pl}} \exp \left( -i \frac{M_{pl}E}{3^2} \sqrt{\rho(a)} \right) \]

= \langle a|0; \Lambda \rangle PV \int_{-\infty}^{k} dx \frac{e^{-ix}}{x} \rightarrow -i \pi \langle a|0; \Lambda \rangle,

where \( k := M_{pl}a^3 \sqrt{\rho(a)/3^2} \).
general argument in Sect. 1, the partition function is
\[ Z = \int da_1 f(a_1) \exp \left( -i \varepsilon(a_1) V_4 \right) \langle f | \psi(t^*; a_1) \rangle, \]  
(C3)
where \( \varepsilon(a_1) \) is the vacuum energy density of this system, which is given by
\[ \varepsilon(a_1) = \begin{cases} V(\phi_1(a_1)) & \text{(for } a_1 > 0) , \\ V(\phi_2(a_1)) & \text{(for } a_1 < 0) . \end{cases} \]  
(C4)
As a result, \( a_1 = 0 \) is apparently the non-analytic point of the vacuum energy \( \varepsilon(a_1) \). See Fig. C2 for an example. Thus, by using Eq. (22), we obtain
\[ e^{-i \varepsilon(a_1) V_4} \sim - \frac{i e^{-i \varepsilon(0) V_4}}{V_4} \times \left[ \left( \frac{V(\phi_1)}{da_1} \right)^{-1} \bigg|_{a_1 = 0^-} - \left( \frac{V(\phi_2)}{da_1} \right)^{-1} \bigg|_{a_1 = 0^-} \right] \delta(a_1). \]  
(C5)
By substituting this into Eq. (C3), we have
\[ Z \sim \frac{1}{V_4} e^{-i \varepsilon(0) V_4} \langle f | \psi(t^*; 0) \rangle. \]  
(C6)
This indicates that the symmetric effective potential is favored by the multi-local action.
