A NONLINEAR ELASTICITY MODEL OF MACROMOLECULAR CONFORMATIONAL CHANGE INDUCED BY ELECTROSTATIC FORCES

YONGCHENG ZHOU, MICHAEL HOLST, AND JAMES ANDREW MCCAMMON

ABSTRACT. In this paper we propose a nonlinear elasticity model of macromolecular conformational change (deformation) induced by electrostatic forces generated by an implicit solvation model. The Poisson-Boltzmann equation for the electrostatic potential is analyzed in a domain varying with the elastic deformation of molecules, and a new continuous model of the electrostatic forces is developed to ensure solvability of the nonlinear elasticity equations. We derive the estimates of electrostatic forces corresponding to four types of perturbations to an electrostatic potential field, and establish the existence of an equilibrium configuration using a fixed-point argument, under the assumption that the change in the ionic strength and charges due to the additional molecules causing the deformation are sufficiently small. The results are valid for elastic models with arbitrarily complex dielectric interfaces and cavities, and can be generalized to large elastic deformation caused by high ionic strength, large charges, and strong external fields by using continuation methods.

1. AN ELECTRO-ELASTIC MODEL OF CONFORMATIONAL CHANGE

A number of fundamental biological processes rely on the conformational change of biomolecules and their assemblies. For instance, proteins may change their configurations in order to undertake new functions, and molecules may not bind or optimally bind to each other to form new functional assemblies without appropriate conformational change at their interfaces or other spots away from binding sites. An understanding of mechanisms involved in biomolecular conformational changes is therefore essential to study structures, functions and their relations of macromolecules. Molecular dynamics (MD) simulations have proven to be very useful in reproducing the dynamics of atomistic scale by tracing the trajectory of each atom in the system [37]. Despite the rapid progress made in the past decade mainly due the explosion of computer power and parallel computing, it remains a significant challenge for MD to study large-scale conformational changes occurring on time-scales beyond a microsecond [5]. Various coarse-grained models and continuum mechanics models are developed in this perspective to complement the MD simulations and to provide computational tools that are not only able to capture characteristics of the specific system, but also able to treat large length and time scales. The prime coarse-grained approaches are the elastic network models, which describe the biomolecules to be beads, rods or domains connected by springs or hinges according to the pre-analysis of their rigidity and the connectivity. Elastic network models are usually combined with normal mode analysis (NMA) to extract the dominant modes of motions, and these modes are then used to explore the structural dynamics at reduced cost [9]. Continuum models do not depend on these rigidity or connectivity analysis. On the contrary, the rigidity of the structure shall be able to be derived from the results of the continuum simulations. Typical continuum models for biomolecular simulations include the elastic deformation of lipid bilayer membranes [35] and the gating of mechanosensitive ion channels [34] induced by given external mechanical loads. It is expected that with more comprehensive continuum models we will be able to simulate the variation of the mechanical loads on the macromolecules with their conformational change, and investigate the dynamics of molecules by coupling the loads and deformation. This article takes an important step in this direction by describing and analyzing the first mathematical model for the interaction between the nonlinear elastic deformation and the electrostatic potential field of macromolecules. Such coupled nonlinear models have tremendous potential in the study of configuration changes and structural stability of large macromolecules such as nucleic acids, ribosomes or microtubules during various electrostatic interactions.

Our model is described below. Let \( \Omega \in \mathbb{R}^3 \) be a smooth open domain whose boundary is noted as \( \partial \Omega \); see Fig. (1). Let the space occupied by the flexible molecules \( \Omega_{mf} \) be a smooth subdomain of \( \Omega \), while the space occupied by the rigid molecule(s) is denoted by \( \Omega_{mr} \). Let the remaining space occupied by the aqueous solvent be \( \Omega_s \). The boundaries of \( \Omega_{mf} \) and \( \Omega_{mr} \) are denoted by \( \Gamma_f \) and \( \Gamma_r \), respectively. We assume that the distance between molecular surfaces and \( \partial \Omega \) is sufficiently large so that the Debye-Hückel approximation can be employed to determine a highly accurate approximate boundary condition for the Poisson-Boltzmann equation. There are charges atoms located inside \( \Omega_{mf} \) and \( \Omega_{mr} \), and changed mobile ions in \( \Omega_s \). The electrostatic potential field generated by these charges induces electrostatic forces on the molecules \( \Omega_{mf} \) and \( \Omega_{mr} \). These forces will in turn cause the configuration
change of the molecules. We shall model this configuration rearrangement as an elastic deformation in this study. Specifically, we will investigate the elastic deformation of molecule \( \Omega_{mf} \) (which is originally in a free state and not subject to any net external force) induced by adding molecule \( \Omega_{mr} \) and changing mobile charge density in \( \Omega_s \). This body deformation leads to the displacement of charges in \( \Omega_{mf} \) and the dielectric boundaries, which simultaneously lead to change of the entire electrostatic potential field. It is therefore interesting to investigate if the deformable molecule \( \Omega_{mf} \) has a final stable configuration in response to the appearance of \( \Omega_{mr} \) and the change of mobile charge density.

Within the framework of an implicit solvent model which treats the aqueous solvent in \( \Omega_s \) as a structure-less dielectric, the electrostatic potential field of the system is described by the Poisson-Boltzmann equation (PBE)

\[
- \nabla \cdot (\epsilon \nabla \phi) + \kappa^2 \sinh(\phi) = \sum_i q_i \delta(x_i) \text{ in } \Omega,
\]

where \( \delta(x_i) \) is the Dirac distribution function at \( x_i \), \( N_f + N_r \) is the number of singular charges of the system including the charges in \( \Omega_{mf} \) (i.e. \( N_f \)) and \( \Omega_{mr} \) (i.e., \( N_r \)). The dielectric constant \( \epsilon \) and the modified Debye-Hückel parameter \( \kappa \) are piecewise constants in domains \( \Omega_{mf}, \Omega_{mr}, \text{ and } \Omega_s \). In particular, \( \kappa = 0 \) in \( \Omega_{mf} \) and \( \Omega_{mr} \) because it models the free mobile ions which appear only in the solvent region \( \Omega_s \). The dielectric constant in the molecule and that in the solvent are denoted with \( \epsilon_m \) and \( \epsilon_s \), respectively. Readers are referred to [26, 27] for the importance of the Poisson-Boltzmann equation in biomolecular electrostatic interactions, and to [2, 3, 4, 28, 29, 30, 31] for the mathematical analysis as well as various numerical methods for the Poisson-Boltzmann equation.

The finite(large) deformation of molecules is essential to our coupled model, but can not be described by a linear elasticity theory. We therefore describe the displacement vector field \( u(x) \) of the flexible molecule \( \Omega_{mf} \) with a nonlinear elasticity model:

\[
- \text{div}(T(u)) = f_b \text{ in } \Omega_{mf}^0 \\
T(u) \cdot n = f_s \text{ on } \Gamma_{mf}^0
\]

where \( f_b \) is the body force, \( f_s \) is the surface force and \( T(u) \) is the second Piola-Kirchhoff stress tensor. In this study we assume the macromolecule is a continuum medium obeying the St Venant-Kirchhoff law, and hence its stress tensor is given by the linear(Hooke’s law) stress-strain relation for an isotropic homogeneous medium:

\[
T(u) = (I + \nabla u)[\lambda \text{Tr}(E(u))]I + 2\mu E(u)].
\]
Here $\lambda > 0$ and $\mu > 0$ are the Lamé constants of the medium, and

$$E(u) = \frac{1}{2}(\nabla u^T + \nabla u + \nabla u^T \nabla u)$$

is the nonlinear strain tensor. The equation (1.3) is nonlinear due to the Piola transformation $(I + \nabla u)$ in $T(u)$, and the quadratic term in the nonlinear strain $E(u)$. The third potential source of nonlinearity, namely a nonlinear stress-strain relation, is not considered here; however, our methods apply to this case as well.

It is noted that Eq.(1.3) is defined in the undeformed molecule body $\Omega_{mf}^0$ with undeformed boundary $\Gamma_{mf}^0$, while the Poisson-Boltzmann equation (1.2) holds true for real deformed configurations. The deformed configuration is unknown before we solved the coupled system. We therefore define a displacement-dependent mapping $\Phi(u)(x) : \Omega^0 \rightarrow \Omega$ and apply this mapping to the the Poisson-Boltzmann equation such that it can also be analyzed on the undeformed molecular configuration. In $\Omega_{mf}$ this map $\Phi(u)(x)$ is $I + u$ where $I$ is the identity mapping. A key technical tool in our work is that this mapping is then harmonically extended to $\Omega$ to obtain the maximum smoothness. Apply this mapping, the Poisson-Boltzmann equation 1.2 changes to be

$$- \nabla \cdot (\epsilon F(u) \nabla \phi) + J(u) \kappa^2 \sinh(\phi) = \sum J(u) q_i \delta(\Phi(x) - \Phi(x_i)) \text{ in } \Omega,$$

where $J(u)$ is the Jacobian of $\Phi(u)$ and

$$F(u) = (\nabla \Phi(u))^{-1} J(u) (\nabla \Phi(u))^{-T}.$$

This matrix $F$ is well defined whenever $\Phi(u)$ is a $C^1$-diffeomorphism [6]. The functions in Eq.(1.4) should be interpreted as the compositions of respective functions in Eq.(1.2) with mapping $\Phi(x)$, i.e., $\phi(x) = \phi(\Phi(x)), \epsilon(x) = \epsilon(\Phi(x))$ and $\kappa(x) = \kappa(\Phi(x))$.

In this paper, we shall analyze the existence of the coupled solution of the elasticity equation (1.3) and the transformed Poisson-Boltzmann equation (1.4). These two equations are coupled through displacement mapping $\Phi(u)$ in the Poisson-Boltzmann equation and the electrostatic forces to be defined later. The solution of this coupled system represents the equilibrium between the elastic stress of the biomolecule and the electrostatic forces to which the biomolecule is subjected. The existence, the uniqueness and the $W^{2,p}$-regularity of the elasticity solution have already been established by Grandmont [6] in studying the coupling of elastic deformation and the Navier-Stokes equations; thus in this work we shall focus on the solution to the transformed Poisson-Boltzmann equation and to the coupled system. We shall define a mapping $S$ from an appropriate space $X_p$ of displacement field $u$ into itself, and seek the fixed-point of this map. This fixed-point, if it exists, will be the solution of the coupled system. A critical step in defining $S$ is the harmonic extension of the Piola transformation from $\Omega_{mf}$ to $\Omega$ and $\mathbb{R}^3$. The regularity of the Piola transformation determines not only the existence of the solution to the transformed Poisson-Boltzmann equation, but also the existence of the solution to the coupled system. Because most of our analysis will be carried out on the undeformed configuration we will still use $\Omega_{mf}, \Omega_{mr}, \Omega_s, \Gamma_f, \Gamma_r$ to denote the undeformed configurations of molecules, the solvent and the molecular interfaces, unless otherwise specified.

The paper is organized as follows. In Section 2 we review a fundamental result concerning the piecewise $W^{2,p}$-regularity of the solutions to elliptic equations in non-divergence form and with discontinuous coefficients. The nonlinear elasticity equation will be discussed in Section 3, where the major results from [6] are presented without
proof. The Piola transformation will be defined, harmonically extended, and then analyzed. In Section 4 we will prove the existence and uniqueness of the solution to the Piola-transformed Poisson-Boltzmann equation, generalizing the results in [2] for the un-transformed case. Both $L^\infty$ and $W^{2,p}$ estimates will be given for the electrostatic potential in the solvent region, again generalizing results in [2]. We will then define the electrostatic forces and estimate these forces by decomposing them into components corresponding to four independent perturbation steps. The estimates of these components are obtained separately and the final estimate of the surface force is assembled from these individual estimates. The coupled system will be finally considered in Section 6 where the mapping $S$ will be defined, and the main result of the paper will be established by applying a fixed-point theorem on this map to give the existence of a solution of the coupled system.

2. Notation and Some Basic Estimates

In what follows $W^{k,p}(\Omega)$ will denote the standard Sobolev space on an open domain $\Omega$, where $\Omega$ can be $\Omega, \Omega_1$ or $\Omega_2$. While solutions of the Poisson-Boltzmann have low global regularity in $\Omega$, we will need to explore and exploit the optimal regularity of the solution in any subdomain of $\Omega$. For this purpose, we define $W^{2,p}(\Omega) = W^{2,p}(\Omega_1) + W^{2,p}(\Omega_2)$ where $+$ is the direct sum. Every function $\phi \in W^{2,p}$ can be written as $\phi(x) = \phi_m(x) + \phi_s(x)$ where $\phi_m(x) \in W^{2,p}(\Omega_m), \phi_s(x) \in W^{2,p}(\Omega_s)$, and has a norm

$$\|\phi\|_{W^{2,p}} = \|\phi_m\|_{W^{2,p}(\Omega_m)} + \|\phi_s\|_{W^{2,p}(\Omega_s)}.$$  (2.1)

Similarly, we define a class of functions $C = C(\Omega)$ which are continuous in either subdomain and may have finite jump on the interface, i.e., a function $a \in C$ is given by $a = a_m + a_s$ where $a_m \in C(\Omega_m), a_s \in C(\Omega_s)$ are continuous functions in their respective domains. The norm in $C$ is defined by

$$\|a\|_C = \|a_m\|_{C(\Omega_m)} + \|a_s\|_{C(\Omega_s)}.$$  

We recall two important results. The first is a technical lemma which will be used for the estimation of the product of two $W^{1,p}$ functions; this is sometimes called the Banach algebra property.

**Lemma 2.1.** Let $3 < p < \infty, 1 \leq q \leq p$ be two real numbers. Let $\Omega$ be a domain in $\mathbb{R}^3$. Let $u \in W^{1,p}(\Omega), v \in W^{1,q}(\Omega)$, then their product $uv$ belongs to $W^{1,q}$, and there exists a constant $C$ such that

$$\|uv\|_{W^{1,q}(\Omega)} \leq C\|u\|_{W^{1,p}(\Omega)}\|v\|_{W^{1,q}(\Omega)}.$$  

For the proof of this lemma we refer to [1]. In this paper we will apply Lemma (2.1) to the case with $p = q$. The second result is a theorem concerning the $L^p$ estimate of elliptic equations with discontinuous coefficients.

**Theorem 2.2.** Let $\Omega$ and $\Omega_1 \subset \subset \Omega$ be bounded domains of $\mathbb{R}^3$ with smooth boundaries $\partial \Omega$ and $\Gamma$. Let $\Omega = (\Omega_1 \cup \Gamma)$ and $\Omega_2 = \Omega \setminus \Omega_1$. Let $A$ be a second order elliptic operator such that

$$(Au)(x) = \begin{cases} (A_1 u)(x) & x \in \Omega_1 \\ (A_2 u)(x) & x \in \Omega_2 \end{cases}, \text{ where } A_i = \sum_{k \leq 2} a_{ik}(x) D^k.$$  

Then there exists a unique solution \( u \in W^{2,p} \) for the interface problem

\[
(Au)(x) = f \text{ in } \Omega \\
[u] = u_2 - u_1 = 0 \text{ on } \Gamma \\
[Bu_n] = B_2 \nabla u_2 \cdot n - B_1 \nabla u_1 \cdot n = h \text{ on } \Gamma \\
u = g \text{ on } \partial \Omega
\]

providing that \( a_{ik} \in C(\Omega), B_i \in C(\Gamma), f \in L^p(\Omega), g \in W^{2-1/p,p}(\partial \Omega), h \in W^{1-1/p,p}(\Gamma) \), where \( n \) is the outside normal to \( \Omega_1 \). Moreover, the following estimate holds true

\[
\|u\|_{W^{2,p}(\Omega)} \leq K \left( \|f\|_{L^p(\Omega)} + \|h\|_{W^{1-1/p,p}(\Gamma)} + \|g\|_{W^{2-1/p,p}(\partial \Omega)} + \|u\|_{L^p(\Omega)} \right), \tag{2.2}
\]

where the constant \( K \) depends only on \( \Omega, \Omega_1, \Omega_2, p \) and the modulus of continuity of \( A \).

Theorem (2.2) is fundamental to various results about elliptic equations with discontinuous coefficients; For example, the global \( H^1 \) regularity and \( H^2 \) estimates of Babuska [20], the finite element approximation of Chen et al. [21], a priori estimates for second-order elliptic interface problems [22], the solution theory and estimates for the nonlinear Poisson-Boltzmann equation [2], and the continuous and discrete a priori \( L^\infty \) estimates for the Poisson-Boltzmann equation along with a quasi-optimal a priori error estimate for Galerkin methods [2] applied to the Poisson-Boltzmann equation. For the proof of Theorem (2.2) and the more general conclusions for high-order elliptic equations with high-order interface conditions we refer to [23, 24].

3. NONLINEAR ELASTICITY AND THE PIOLA TRANSFORMATION

We first state a theorem concerning the existence, uniqueness, regularity and the estimation of the solution to the nonlinear elasticity equation [6]:

**Theorem 3.1.** Let the body force \( f_b \in L^p(\Omega_{mf}) \) and the surface force \( f_s \in W^{1-1/p,p}(\Gamma_f) \), where \( 3 < p < \infty \). There exists a neighborhood of 0 in \( L^p(\Omega_{mf}) \times W^{1-1/p,p}(\Gamma_f) \) such that if \( (f_b, f_s) \) belongs to this neighborhood then there exists a unique solution \( u \in W^{2,p}(\Omega_{mf}) \cap W^{1,p}_{0,\Gamma_{f0}}(\Omega_{mf}) \) of

\[
\begin{align*}
-\text{div}(\mathbf{T}(\mathbf{u})) &= f_b \text{ in } \Omega_{mf}, \\
\mathbf{T}(\mathbf{u}) \mathbf{n} &= f_s \text{ on } \Gamma_f \setminus \Gamma_{f0}, \\
u &= 0 \text{ on } \Gamma_{f0}, \tag{3.1}
\end{align*}
\]

\[
\int_{\Gamma_f} (I + \nabla \mathbf{u}) J(\mathbf{u})(I + \nabla \mathbf{u})^{-T} \cdot \mathbf{n} = 3|\Omega_{mf}|,
\]

where \( \Gamma_{f0} \) is a subset of \( \Gamma_f \) equipped with homogeneous Dirichlet boundary condition, \( I \) is the unit matrix. The last equation represents the incompressibility condition of the elastic deformation. Moreover, the solution can be estimated with respect to the force data:

\[
\|u\|_{W^{2,p}(\Omega_{mf})} \leq C(\|f_b\|_{L^p(\Omega_{mf})} + \|f_s\|_{W^{1-1/p,p}(\Gamma_f)}). \tag{3.2}
\]

**Proof.** See [7].

**Remark 3.2.** It is noticed that \( u \in C^{1,1-3/p}(\Omega_{mf}) \) because of the continuous embedding of \( W^{2,p}(\Omega_{mf}) \) in \( C^{1,1-3/p}(\Omega_{mf}) \) for \( p > 3 \).

The displacement field \( \mathbf{u}(x) \) solved from Eq.(3.1) naturally defines a mapping \( \Phi(\mathbf{u}) = \mathcal{I} + \mathbf{u} \) in \( \Omega_{mf} \) where \( \mathcal{I} \) is the identity mapping. This mapping \( \Phi(\mathbf{u})(x) \) has to be appropriately extended into \( \mathbb{R}^3 \setminus \overline{\Omega}_{mf} \) to yield a global transformation for the Poisson-Boltzmann
equation. It is critical in what follows that this extension has various favorable properties, which leads us to define a global mapping by harmonic extension:

$$\Phi(u) = \begin{cases} I + u & x \in \Omega_m \\ I + w & \text{otherwise} \end{cases}$$

(3.3)

where $w$ solves

$$\Delta w = 0 \text{ in } \mathbb{R}^3 \setminus \Omega_m, \quad w = u \text{ on } \Gamma_f.$$  

(3.4)

The following crucial lemma concerns the regularity of $\Phi(u)$ and the invertibility of $\nabla \Phi(u)$:

**Lemma 3.3.** Let $\Phi(u)$ be defined in Eq. (3.3), we have

(a) $\Phi(u) \in W^{2,p}(\Omega_m)$ and $\Phi(u) \in C^\infty(\mathbb{R}^3 \setminus \Omega_m)$.

(b) There exists a constant $M > 0$ such that for all $\|u\|_{W^{2,p}(\Omega)} \leq M$, $\nabla \Phi(u)$ is an invertible matrix in $W^{1,p}(\Omega_m)$ and in $C^\infty(\mathbb{R}^3 \setminus \Omega_m)$.

(c) Under condition (b), $\Phi(x)$ is one-to-one on $\mathbb{R}^3$, and is a $C^1$-diffeomorphism from $\Omega_m$ to $\Phi(u)(\Omega_m)$, and is a $C^\infty$-diffeomorphism from $\mathbb{R}^3 \setminus \Omega_m$ to $\Phi(u)(\mathbb{R}^3 \setminus \Omega_m)$.

**Proof.** That $\Phi(u) \in W^{2,p}(\Omega_m)$ follows directly from its definition. Also, of $\Phi(u) \in C^\infty(\mathbb{R}^3 \setminus \Omega_m)$ since $\Phi(u) = I + w$ while $w$ is harmonic hence analytical in $\Phi(u) \in C^\infty(\mathbb{R}^3 \setminus \Omega_m)$ because it is the solution of the Laplace equation (3.4). For the invertibility of $\Phi(u)$ in $W^{1,p}(\Omega_m)$ we refer to Lemma 2 in [6] or Theorem 5.5.1 in [7], which says that if $u \in \Omega_m$ is differentiable and

$$|\nabla u(x)| < C$$

for some constant depending on $\Omega_m$, then $\nabla \Phi(u) = I + \nabla u > 0 \forall x \in \Omega_m$ and $I + \nabla u$ is injective on $\Omega_m$. The invertibility of $\nabla \Phi(u)$ therefore follows from the facts that $u \in C^{1,1-3/p(\Omega_m)}$ such that for sufficiently small $M$

$$|\nabla u| \leq \|u\|_{C^{1,1-3/p}(\Omega_m)} \leq C_1 \|u\|_{W^{2,p}(\Omega_m)} = C_1 M \leq C.$$

To prove the invertibility of $\nabla \Phi(u) = I + \nabla w$ in $\mathbb{R}^3 \setminus \Omega_m$ we notice the following estimate for the first derivative of the solution to Laplace equation [19]:

$$|\nabla w| \leq \|w\|_{C^1(\mathbb{R}^3 \setminus \Omega_m)} \leq C_2 \|u\|_{C^{1,1-3/p(\Gamma)}} \leq C_2 M \leq C,$$

Therefore if $M$ is chosen such that

$$M \leq \frac{C}{\max\{C_1,C_2\}}$$

(3.5)

$\nabla \Phi(u)$ is an invertible matrix in $\mathbb{R}^3$. □

**Remark 3.4.** It follows from Lemma (3.3) that the matrix $F(u)$ in Eq. (1.5) is well-defined, symmetric and positive definite. More precisely, we have that the maps $F(u)(x) \in C^{0,1-3/p(\Omega_m)}$ and $F(u)(x) \in C^\infty(\mathbb{R}^3 \setminus \Omega_m)$. On the other hand, as a mapping from $u \in W^{2,p}(\Omega_m)$ to $F(u) \in C^\infty(\mathbb{R}^3 \setminus \Omega_m)$, $F(u)$ is infinitely differentiable with respect to $u$. In all what follows we will write $F(u)$ and $J(u)$ as $F$ and $J$ only, keeping in mind that they are $u$ dependent.
4. PRELIMINARY RESULTS FOR THE POISSON-BOLTZMANN EQUATION

4.1. The Poisson-Boltzmann equation with Piola transformation. The rigorous analysis and numerical approximation of solutions to the Poisson-Boltzmann equation (1.2) or its transformed version (1.4) are generally subject to three major difficulties: 1) the singular charge distribution, 2) the discontinuous dielectric constant on the molecular surface and 3) the strong exponential nonlinearities. However, it was recently demonstrated [2] that as far as the untransformed Poisson-Boltzmann equation (1.2) is concerned, some of these difficulties can be side-stepped by individually considering the singular and the regular components of the solution. Specifically, the potential solution is decomposed to be

\[ \phi = G + \phi^r = G + \phi^l + \phi^n \]  

(4.1)

where the singular component

\[ G = \sum_i \frac{q_i}{\epsilon_m |x - x_i|} \]

is the solution of the Poisson equation

\[ -\nabla \cdot (\epsilon_m \nabla G) = \rho_f := \sum_i q_i \delta(x_i) \text{ in } \mathbb{R}^3; \]  

(4.2)

while \( \phi^l \) is the linear component of the electrostatic potential which satisfies

\[ -\nabla \cdot (\epsilon \nabla \phi^l) = -\nabla \cdot ((\epsilon - \epsilon_m) \nabla G) \text{ in } \Omega, \]

\[ \phi^l = g - G \text{ on } \partial\Omega, \]  

(4.3)

and the nonlinear component \( \phi^n \) solves

\[ -\nabla \cdot (\epsilon \nabla \phi^n) + \kappa^2 \sinh(\phi^n + \phi^l + G) = 0 \text{ in } \Omega, \]

\[ \phi^n = 0 \text{ on } \partial\Omega, \]  

(4.4)

where

\[ g = \sum_{i=1}^N q_i e^{-\kappa|x - x_i|} \epsilon_a |x - x_i| \]  

(4.5)

is the boundary condition of the complete Poisson-Boltzmann equation (1.2). Such a decomposition scheme removes the point charge singularity from the original Poisson-Boltzmann and it was shown in [2] that the regular component of the electrostatic potential \( \phi^r = \phi^l + \phi^n \) belongs to \( H^1(\Omega) \) although the entire solution \( G + \phi^r \) does not. The most prominent advantage of this decomposition lies in the fact that the regular component represents the reaction potential field of the system, which can be directly used to compute the solvation energy and other associated important properties of the system. It is not necessary to solve the Poisson-Boltzmann equation twice, once with uniform vacuum dielectric constant and vanishing ionic strength and the other with real physical conditions, to obtain the reaction field [29]. As to be shown later on, the identification of this regular potential component as the reaction field also facilitates the analysis and the computation of the electrostatic forces.

Applying the similar decomposition to the transformed Poisson-Boltzmann equation we get an equation for the singular component \( G \):

\[ -\nabla \cdot (\epsilon_m F \nabla G) = J \rho_f \text{ in } \mathbb{R}^3, \]  

(4.6)
and an equation for the regular component $\phi^r$:

$$-\nabla \cdot (\epsilon F \nabla \phi^r) + J \kappa^2 \sinh(\phi^r + G) = \nabla \cdot ((\epsilon - \epsilon_m) F \nabla G) \quad \text{in} \quad \Omega,$$

$$\phi^r = g - G \quad \text{on} \quad \partial \Omega. \quad (4.7)$$

We shall prove the existence of $\phi^r$ in Eq.(4.7) and give its $L^\infty$ bounds by individually considering the equation for the linear component $\phi^l$:

$$-\nabla \cdot (\epsilon F \nabla \phi^l) = \nabla \cdot ((\epsilon - \epsilon_m) F \nabla G) \quad \text{in} \quad \Omega,$$

$$\phi^l = g - G \quad \text{on} \quad \partial \Omega, \quad (4.8)$$

and the equation for the nonlinear component $\phi^n$:

$$-\nabla \cdot (\epsilon F \nabla \phi^n) + J \kappa^2 \sinh(\phi^n + \phi^l + G) = 0 \quad \text{in} \quad \Omega,$$

$$\phi^n = 0 \quad \text{on} \quad \partial \Omega. \quad (4.9)$$

As mentioned above, the functions $G, \phi^l, \phi^n, \rho^l$ and $\kappa$ in Eqs.(4.6) through (4.9) shall be interpreted as the compositions of the corresponding entries of these functions in untransformed equations (4.2) through (4.4) with the Piola transformation $\Phi(x)$, i.e., $g = g(\Phi(x)), G = G(\Phi(x)), \phi^l = \phi^l(\Phi(x)), \phi^n = \phi^n(\Phi(x)), \rho^l = \rho^l(\Phi(x)), \kappa = \kappa(\Phi(x))$.

4.2. **Regularity and estimates for the singular solution component $G$.** We first study the Eq. (4.6) for the singular component of electrostatic potential. We remark that the linear and nonlinear PB equations have the same singular component of the electrostatic potential. The solution of this singular component is the Green’s function for the elliptic operator $L$ defined by

$$Lu = -\nabla \cdot (\epsilon_m F \nabla u). \quad (4.10)$$

We shall use the following theorem [11] concerning the regularity and the estimate of the Green’s function:

**Theorem 4.1.** Let $\Omega$ be an open set in $\mathbb{R}^3$. Suppose the elliptic operator

$$Lu = \sum_{i,j=1}^n \frac{\partial}{\partial x_j} (a_{ij} \frac{\partial u}{\partial x_i})$$

is uniformly elliptic and bounded, while the coefficients $a_{ij}$ satisfying

$$|a_{ij}(x) - a_{ij}(y)| \leq \omega(|x - y|)$$

for any $x, y \in \Omega$, and the non-decreasing function $\omega(x)$ satisfies

$$\omega(2t) \leq K \omega(t) \text{ for some } K > 0 \text{ and all } t > 0,$$

$$\int_{\mathbb{R}} \frac{\omega(t)}{t} dt < \infty.$$

Then for the corresponding Green’s function $G$ the following six inequalities are true for any $x, y \in \Omega$:

(a) $G(x, y) \leq K|x - y|^{-1},$
(b) $G(x, y) \leq K \delta(x)|x - y|^{-2},$
(c) $G(x, y) \leq K \delta(x) \delta(y)|x - y|^{-3},$
(d) $|\nabla_x G(x, y)| \leq K|x - y|^{-2},$
(e) $|\nabla_y G(x, y)| \leq K \delta(y)|x - y|^{-3},$
(f) $|\nabla_x \nabla_y G(x, y)| \leq K|x - y|^{-3},$

where $\delta(y) = \text{dist}(y, \partial \Omega)$ and the general constant $K = K(a_{ij}, \omega, \Omega)$. 
From this theorem we can derive the regularity of the Green's function of the operator 
(4.10). Indeed, by Sobolev embedding $\epsilon_m F \in C^{0,1-3/p}(\mathbb{R}^3)$, therefore it satisfies 
the conditions on $a_{ij}$ in this theorem provided that $\omega(t) = K t^{3/p}$. We then conclude that 
the singular component of the electrostatic potential $G \in W^{1,\infty}(\Omega \setminus B_r(x_i))$. On the other 
hand, from Eq. (4.6) we know that $G(\Phi(u)(x))/J(x_i)$ itself is the Green's function of 
operator (4.10) if $F$ is generated by the Piola transformation according to (1.5) and $J$ is 
the corresponding Jacobian. Thus the Green's function of differential operator (4.10) 
begins to $W^{2,p}(\Omega \setminus B_r(x_i))$ since it is the composition of the Green's function of Laplace 
operator, which is of $C^{\infty}(\Omega \setminus B_r(x_i))$, and the Piola transformation, which is of $W^{2,p}(\Omega)$. 
Higher regularity of $G$ in $\Omega_s$ can be derived thanks to the harmonic extension of $u$ to 
$\mathbb{R}^3 \setminus \overline{\Omega}_{mf}$. In particular, because all charges are located in $\Omega_{mf}$ and $\Omega_{mr}$ the 
Poisson equation (4.6) appears a Laplace equation
\[ \nabla (\epsilon \nabla G) = 0 \quad \text{in} \quad \Omega_s, \]
hence $G(x) \in C^\infty(\Omega_s)$, since $\Omega_s$ is a smooth open domain and $F \in C^\infty(\Omega_s)$.

In addition to the regularity of the Green's function, we have following estimates of $G$ 
with respect to $F$ and $J$.

**Lemma 4.2.** For any given molecule the Green's function $G$ of operator (4.10) has estimates

(a) $\|G\|_{L^\infty(\Omega_s)} \leq C \|J\|_{L^\infty(\Omega)}$.

(b) $\|\nabla G\|_{L^\infty(\Omega_s)} \leq C \|J\|_{L^\infty(\Omega)}$.

If in addition $\|F - I\|_{W^{1,\infty}(\Omega)} \leq C_f$, $\|J - 1\|_{W^{1,p}(\Omega)} \leq C_J$ for some constant $C_f$ and $C_J$, then

(c) $\|G\|_{L^p(\partial \Omega)} \leq C \|G\|_{L^\infty(\Omega_s)}$.

(d) $\|g \circ \Phi\|_{W^{2-1/p,p}(\partial \Omega)} \leq C_g \|g\|_{W^{2,p}(\Omega_s)}$.

(e) $\|g \circ \Phi - G\|_{W^{2-1/p,p}(\partial \Omega)} \leq C_g \|g\|_{W^{2,p}(\Omega_s)} + C_G \|G\|_{L^\infty(\Omega_s)}$.

(f) $\|F \nabla G\|_{W^{1-1/p,p}(\Gamma)} \leq C_\Gamma \|G\|_{L^\infty(\Omega_s)}$ for some set $\Omega_s$.

**Proof.** This $\|J\|_{L^\infty(\Omega_s)}$ is well defined since $J$ is uniformly continuous in $\overline{\Omega}_s$. To prove 
(a) and (b) we define $q_{\text{max}} = \max \{ |q_i| \}$ and

$$\|\nabla x G_i(x, x_i)\|_{L^\infty(\Omega_s)} = \frac{K}{\delta^2}, \quad \|G_i(x, x_i)\|_{L^\infty(\Omega_s)} = \frac{K}{\delta}$$

where $\delta$ is the smallest distance between $x \in \partial \Omega$ and singular charges at $x_i$. This smallest 
distance is related to the radii of atoms used in defining the molecular surface. In the 
sense of Connolly's molecular surface, $\delta$ is simply the smallest van der Waals radius of 
the atoms which have contact surface [33]. We can therefore bound $G$ and its gradient with

$$\|G\|_{L^\infty(\Omega_s)} = \left\| \sum_i J q_i G_i \right\|_{L^\infty(\Omega_s)} \leq N q_{\text{max}} \|J\|_{L^\infty(\Omega_s)} \|G_i\|_{L^\infty(\Omega_s)}$$

$$= \frac{\|J\|_{L^\infty(\Omega)} N K q_{\text{max}}}{\delta}, \quad (4.11)$$

$$\|\nabla G\|_{L^\infty(\Omega_s)} = \left\| \sum_i J q_i \nabla G_i \right\|_{L^\infty(\Omega_s)} \leq N q_{\text{max}} \|J\|_{L^\infty(\Omega_s)} \|\nabla x G_i\|_{L^\infty(\Omega_s)}$$

$$= \frac{\|J\|_{L^\infty(\Omega)} N K q_{\text{max}}}{\delta^2}, \quad (4.12)$$

where $N$ is the total number of singular charges and $\|J\|_{L^\infty(\Omega_s)}$ is the maximum Jacobian 
on $\Gamma$. 

Applying the domain $C$ with a constant inequality following the estimate of the composite function in Sobolev space [12], we have the inequality

$$g \circ \Phi = \sum_i q_i \frac{e^{-\delta|\Phi(x) - \Phi(x_i)|}}{\epsilon_s|\Phi(x) - \Phi(x_i)|}.$$ 

Following the estimate of the composite function in Sobolev space [12], we have the inequality

$$\|g \circ \Phi\|_{W^{2-1/p,p}(\partial\Omega)} \leq \|g\|_{W^{2,p}(\Omega_s)}$$

$$\leq C(1 + \|\Phi\|_{L^\infty(\Omega_s)})(1 + \|\Phi\|_{W^{2,p}(\Omega_s)\|g\|_{W^{2,p}(\Omega_s)}}$$

$$:= C_g\|g\|_{W^{2,p}(\Omega_s)}$$

(4.13)

with a constant $C_g$ depending upon $\Phi(x)$. Here we choose to bound $\|g \circ \Phi\|_{W^{2-1/p,p}(\partial\Omega)}$ by $\|g \circ \Phi\|_{W^{2,p}(\Omega_s)}$ instead of $\|g \circ \Phi\|_{W^{2,p}(\Omega)}$ since the latter is not well defined due to the singular nature of $g$.

The validity of inequalities (e) and (f) follows from the estimate of $\|G\|_{W^{2,p}(\Omega_s)}$. This $\Omega_s$ is chosen such that $\Omega_s \subset \Omega_s^{'}$. For example, we can choose $\Omega_s^{'}$ to be the union of $\Omega_s$, $\Gamma$, $\partial\Omega$, the domain

$$\Omega_s^{-} = \{x|x \in \Omega_m, \text{dist}(x, \Gamma) < \frac{\delta}{2}\}$$

and the domain

$$\Omega_s^{+} = \{x|x \notin \Omega, \text{dist}(x, \partial\Omega) < \frac{\delta}{2}\}.$$ 

Applying the $L^p$ estimate to Eq.(4.6) in $\Omega_s$ we obtain

$$\|G\|_{W^{2-1/p,p}(\partial\Omega)} \leq C\|G\|_{W^{2,p}(\Omega_s)} \leq C(\Phi)\|G\|_{L^p(\Omega_s^{''})} \leq C(\Phi)\|G\|_{L^\infty(\Omega_s^{''})}$$

$$:= C_G\|G\|_{L^\infty(\Omega_s^{''})},$$

(4.14)

where the second inequality is a consequence of the $L^p$ estimate of the solution to $-\nabla \cdot (\epsilon\mathbf{F}\nabla G) = 0$ in $\Omega_s^{''}$. The coefficient $C_G = C(\Phi)$ depends on the ellipticity constants of $\mathbf{F}$ and its moduli of continuity on $\Omega_s$, hence is bounded as long as $\mathbf{F}$ is bounded. By combining Eqs.(4.14) and (4.13) we get (c). For the last estimate we notice

$$\|\mathbf{F}\nabla G\|_{W^{1-1/p,p}(\Gamma)} \leq C\|[\epsilon]\mathbf{F}\nabla G\|_{W^{1,p}(\Omega_s)}$$

$$\leq C\|\mathbf{F}\|_{W^{1,p}(\Omega_s)}\|\nabla G\|_{W^{1,p}(\Omega_s)}$$

$$\leq C\|\mathbf{F}\|_{W^{1,p}(\Omega_s)}\|G\|_{W^{2,p}(\Omega_s)}$$

$$\leq C(\mathbf{F})\|\mathbf{F}\|_{W^{1,p}(\Omega_s)}\|G\|_{L^p(\Omega_s^{''})}$$

$$\leq C\|\mathbf{F}\|_{W^{1,p}(\Omega_s)}\|G\|_{L^\infty(\Omega_s^{''})}$$

$$:= C_G\|G\|_{L^\infty(\Omega_s^{''})}.$$ 

(4.15)

\[ \square \]

\textbf{Remark 4.3.} $\|G\|_{L^\infty(\Omega_s^{''})}$ can also be estimated by Eq.(4.11) if $\delta$ is replaced by $\delta/2$ and $\|J\|_{L^\infty(\Omega)}$ is replaced by $\|J\|_{L^\infty(\Omega,\Omega^{''})}$. \[ \square \]
4.3. Regularity and estimates for the regular linearized solution component $\phi^r$. We consider an elliptic interface problem modified from the Poisson-Boltzmann equation

$$
-\nabla \cdot (\epsilon F \nabla \phi^r) + J \kappa^2 (\phi^r + G) = \nabla \cdot ((\epsilon - \epsilon_m) F \nabla G) + f \text{ in } \Omega \\
[\phi^r] = \phi^r_s - \phi^r_m = 0, \text{ on } \Gamma \\
\phi^r = g - G \text{ on } \partial \Omega,
$$

(4.16)

where $[\epsilon] = \epsilon_s - \epsilon_m$ is the jump of dielectric constant and $f \in L^p(\Omega)$ is a given function. The equation for the regular potential solution of the linear Poisson-Boltzmann equation is a special case of (4.16) with $f = 0$. We remark that the regular component of the linear Poisson-Boltzmann equation in the absence of the Piola transformation represents a typical elliptic equation with discontinuous coefficients, for which Theorem (2.2) can be directly applied to get the existence and the estimate. In fact, the potential solution in this case is smooth in every subdomain (Proposition 1.4, [16]). When the Piola transformation is incorporated, the coefficients of the Eq. (4.16) are not smooth and we have to rebuild the regularity and the estimate of the regular potential solution $\phi^r$, as summarized in the following theorem.

**Theorem 4.4.** There exists a unique solution $\phi^r$ of (4.16) in $H^1(\Omega)$. Moreover, there exists a positive constant $C_f$ such that if $\|F - I\|_{W^{1,p}(\Omega)} \leq C_f$ then $\phi^r$ belongs to $W^{2,p}(\Omega)$ and the following estimate holds true

$$
\|\phi^r\|_{W^{2,p}(\Omega)} \leq C_2 \left( \|G\|_{L^p(\Omega)} + \|f\|_{L^p(\Omega)} + \|g - G\|_{W^{2-1/p,p}(\partial \Omega)} + \|F \nabla G\|_{W^{1-1/p,p}(\Gamma)} \right).
$$

(4.17)

Before proving this $W^{2,p}$ estimate, we first establish a lemma concerning the $L^\infty$ estimate of a linear elliptic interface problem.

**Lemma 4.5.** Let $\phi^r$ solve

$$
-\nabla \cdot (\epsilon \nabla \phi^r) + b \phi^r = f \text{ in } \Omega \\
[\phi^r] = 0, \text{ on } \Gamma \\
[\epsilon \phi^r_n] = 0, \text{ on } \Gamma \\
\phi^r = g \text{ on } \partial \Omega,
$$

where $\epsilon$ is a piecewise constant as defined for problem (4.16) and $b > 0$ is a given real number, $f(x) \in L^p(\Omega), g \in H^1(\Omega), p > 3$. Then

$$
\|\phi^r\|_{L^\infty} \leq C \left( \|f\|_{L^p(\Omega)} + \|g\|_{H^{1/2}(\partial \Omega)} \right)
$$

(4.18)

**Proof.** The existence of unique solution $\phi^r \in W^{2,p} \subset H^1(\Omega)$ can be directly deduced from Theorem (2.2). We follow [2] and let $\phi^r = \phi^l + \phi^n$ where $\phi^l$ solves

$$
-\nabla \cdot (\epsilon \nabla \phi^l) = f \text{ in } \Omega \\
[\phi^l] = 0 \text{ on } \Gamma, \\
[\epsilon \phi^l_n] = 0 \text{ on } \Gamma, \\
\phi^l = g \text{ on } \partial \Omega,
$$

and $\phi^n$ solves

$$
-\nabla \cdot (\epsilon \nabla \phi^n) + b(\phi^n + \phi^l) = 0 \text{ in } \Omega, \\
[\phi^n] = 0 \text{ on } \Gamma, \\
[\epsilon \phi^n_n] = 0 \text{ on } \Gamma, \\
\phi^n = 0 \text{ on } \partial \Omega.
$$
It is well known [20, 21] that
\[ \| \phi^t \|_{L^\infty} \leq C \left( \| f \|_{L^p(\Omega)} + \| g \|_{H^{1/2}(\partial \Omega)} \right), \]
while for \( \phi^n \) we claim that
\[ -\| \phi^t \|_{L^\infty} \leq \| \phi^n \|_{L^\infty} \leq \| \phi^t \|_{L^\infty}. \]
To prove this assertion we define \( \phi_t = \max(\phi^n - \alpha, 0) \) where \( \alpha = \| \phi^t \|_{L^\infty}. \) Then the trace \( \text{Tr}(\phi_t) = 0 \) hence \( \phi_t \in H^1_0(\Omega) \) by definition. Consider the weak formulation of the problem for \( \phi^n \) with test function \( \phi_t \)
\[ (\epsilon \nabla \phi^n, \nabla \phi_t) + b(\phi^n + \phi^t, \phi_t) = 0. \]
Since \( \phi_t \geq 0 \) wherever \( \phi^n \geq \alpha, \) we have
\[ b(\phi^n + \phi^t, \phi_t) = \int_{\phi^n \geq \alpha} b(\phi^n + \phi^t) \phi_t dx + \int_{\phi^n < \alpha} b(\phi^n + \phi^t) \phi_t dx \geq 0, \]
and
\[ 0 \geq (\epsilon \nabla \phi^n, \nabla \phi_t) = (\epsilon \nabla (\phi^n - \alpha), \nabla \phi_t) = (\epsilon \nabla \phi_t, \nabla \phi_t) \geq 0. \]
Thus \( \nabla \phi_t = 0, \) and \( \phi_t = 0 \) or \( \phi^n \leq \alpha \) in \( \Omega \) follows from the Poincare inequality. By defining \( \phi_t = \min(\phi^n + \alpha, 0) \) and following the same procedure we can verify that \( \phi^n \geq -\alpha. \) The lemma shall be finally proved by combining the estimates of \( \phi^t \) and \( \phi^n. \)

**Proof. of Theorem (4.4).** Consider the general weak formulation of the elliptic equation in problem (4.16), i.e., find \( \phi^* = u \in H^1_0(\Omega) \) such that \( A(u, v) = F(v), \forall v \in H^1_0(\Omega) \) where
\[
A(u, v) = \int_{\Omega} (F \nabla u \nabla v + J \kappa^2 uv) dx,
\]
\[
F(v) = \int_{\Omega} (\nabla \cdot ((\epsilon - \epsilon_m) F \nabla G) - J \kappa^2 G + f) dx - A(g - G, v).
\]
We shall apply the Lax-Milgram theorem to obtain the existence and the uniqueness of a weak solution \( \phi^* \in H^1(\Omega) \) to (4.16). Hence we must show that \( F(\cdot) \) is bounded, and \( A(\cdot, \cdot) \) is bounded and coercive with the assumptions on the coefficient matrix \( F \) and the Jacobian \( J. \) Consider the bilinear form \( A(\cdot, \cdot). \) The Piola transform matrix \( F \) is positive definite, hence \( F \nabla v \cdot \nabla v \geq \gamma |\nabla v|^2 \) for some \( \gamma > 0. \) This inequality and the positiveness of Jacobian \( J \) give
\[
A(v, v) = \int_{\Omega} (F \nabla v \cdot \nabla v + J \kappa^2 v^2) dx \geq \int_{\Omega} (\gamma |\nabla v|^2 + J \kappa^2 v^2) dx \geq \lambda |u|_{H^1(\Omega)}^2
\]
\[
= \gamma \left( \frac{1}{2} |v|_{H^1(\Omega)}^2 + \frac{1}{2} |v|_{L^2(\Omega)}^2 \right) \geq \gamma \left( \frac{1}{2 \theta^2} |v|_{L^2(\Omega)}^2 + \frac{1}{2} |v|_{H^1(\Omega)}^2 \right)
\]
\[
\geq m \left( |v|_{L^2(\Omega)}^2 + |v|_{H^1(\Omega)}^2 \right) = m |v|_{H^1(\Omega)}^2,
\]
where in the second inequality we applied the Poincare inequality with constant \( \theta. \) Thus we verified that \( A(\cdot, \cdot) \) is coercive, with coercivity constant \( m = \min\{\gamma/(2\theta^2), \gamma/2\}. \)
On the other hand,

\begin{equation}
|A(u, v)| = \left| \int_{\Omega} (F \nabla u \cdot \nabla v + J \kappa^2 uv) dx \right| 
\end{equation}

\begin{equation}
\leq \sum_{i,j} \int_{\Omega} |F_{ij} D_i u D_j v| dx + \int_{\Omega} |J \kappa^2 uv| dx 
\end{equation}

\begin{equation}
\leq \sum_{i,j} \|F_{ij}\|_{L^\infty(\Omega)} \|D_i u D_j v\|_{L^1(\Omega)} + \kappa^2 \|J\|_{L^\infty} \|uv\|_{L^1(\Omega)} 
\end{equation}

\begin{equation}
\leq \sum_{i,j} \|F_{ij}\|_{L^2(\Omega)} \|u\|_{H^1(\Omega)} \|v\|_{H^1(\Omega)} + \kappa^2 \|J\|_{L^\infty} \|u\|_{L^2(\Omega)} \|v\|_{L^2(\Omega)} 
\end{equation}

\begin{equation}
\leq K_1 \|u\|_{H^1(\Omega)} \|v\|_{H^1(\Omega)} 
\end{equation}

which proves that $A(\cdot, \cdot)$ is bounded with constant $K_1 = \sum_{i,j} \|F_{ij}\|_{L^\infty} + \kappa^2 \|J\|_{L^\infty}$. This constant $K_1$ is finite because $F, J$ belong to $W^{1,p}(\Omega)$ which is compactly embedded in $C^0(\overline{\Omega})$ for $p > 3$.

In order to apply the Lax-Milgram theorem it remains to show that $F(v)$ is bounded on $H^1_0(\Omega)$. We have

\begin{equation}
|F(v)| \leq \int_{\Omega} (\epsilon - \epsilon_m) F \nabla G v dx + \int_{\Omega} |J \kappa^2 G v + f v| dx + |A(g - G, v)| 
\end{equation}

\begin{equation}
= \int_{\Omega_m} (\epsilon_m - \epsilon_m) F \nabla G v dx + \int_{\Omega_s} (\epsilon_s - \epsilon_m) F \nabla G v dx + \int_{\Omega} |J \kappa^2 G v + f v| dx + |A(g - G, v)| 
\end{equation}

\begin{equation}
= \int_{\Omega_s} (\epsilon_s - \epsilon_m) F \nabla G v dx + \int_{\Omega} |J \kappa^2 G v + f v| dx + |A(g - G, v)| 
\end{equation}

\begin{equation}
\leq \int_{\Omega_s} |(\epsilon_s - \epsilon_m) F \nabla G v| dx + \int_{\Omega} |J \kappa^2 G v + f v| dx + |A(g - G, v)| 
\end{equation}

\begin{equation}
\leq [\epsilon] \|F \nabla G\|_{L^2(\Omega)} \|v\|_{L^2(\Omega)} + (\kappa^2 \|J G\|_{L^2(\Omega)} + \|f\|_{L^2(\Omega)}) \|v\|_{L^2(\Omega)} + K_1 \|g - G\|_{H^1(\Omega)} \|v\|_{H_1^1(\Omega)} 
\end{equation}

\begin{equation}
= (\epsilon) \|F \nabla G\|_{L^2(\Omega)} + \kappa^2 \|J G\|_{L^2(\Omega)} + \|f\|_{L^2(\Omega)} + K_1 \|g - G\|_{H^1(\Omega)} \|v\|_{H^1(\Omega)} 
\end{equation}

hence $F(\cdot)$ is a bounded linear functional on $H^1_0(\Omega)$.

We now proceed to show the regularity result and the estimate of $\phi^r$ following the similar iterative technique in [6]. For this purpose we introduce a sequence $\{\phi^r_N\}$ generated by

\begin{equation}
- \nabla \cdot (\epsilon \nabla \phi^r_N) + J \kappa^2 \phi^r_N = \nabla \cdot ((\epsilon - \epsilon_m) F \nabla G) - J \kappa^2 G + \nabla \cdot (\epsilon (F - I) \nabla \phi^r_{N-1}) \text{ in } \Omega, 
\end{equation}

\begin{equation}
[\phi^r_N] = 0 \text{ on } \Gamma, 
\end{equation}

\begin{equation}
\phi^r_N = g - G \text{ on } \partial \Omega, 
\end{equation}
and prove that \( \phi_N^r \in \mathcal{W}^{2,p}(\Omega) \) and \( \phi_N^r \) converges to the unique solution \( \phi^r \) of (4.16) in \( \mathcal{W}^{2,p}(\Omega) \) as \( N \to \infty \). The first term \( \phi_0^r \) of the sequence solves

\[
- \nabla \cdot (\epsilon \nabla \phi_0^r) + \int k^2 \phi_0^r = \nabla \cdot ((\epsilon - \epsilon_m)F \nabla G) - \int k^2 G \text{ in } \Omega
\]

\[
[\phi_0^r] = 0, \text{ on } \Gamma
\]

\[
\phi_0^r = g - G \text{ on } \partial \Omega,
\]

therefore it belongs to \( \mathcal{W}^{2,p}(\Omega) \) according to Theorem (2.2). Suppose now that \( \phi_{N-1}^r \in \mathcal{W}^{2,p}(\Omega) \), then \( \nabla \phi_{N-1}^r \in \mathcal{W}^{1,p}(\Omega) \) and \( \nabla \cdot (\epsilon (F - 1) \nabla \phi_{N-1}^r) \in L^p(\Omega) \) following from Lemma (2.1). Thus problem (4.23) also has a unique solution \( \phi_N^r \in \mathcal{W}^{2,p}(\Omega) \) for all integer \( N \) according to Theorem (2.2). To prove that \( \phi_N^r \) converges to the unique solution \( \phi^r \) of problem (4.16), we estimate \( \| \phi_N^r - \phi_{N-1}^r \|_{\mathcal{W}^{2,p}(\Omega)} \) and show it is decreasing as \( N \to \infty \). By subtracting the equations in (4.16) for \( N \) from those for \( N - 1 \) we obtain a problem for \( \phi_N^r - \phi_{N-1}^r \). Applying Theorem (2.2) again we know that this problem has a unique solution \( \mathcal{W}^{2,p}(\Omega) \) which has an estimate

\[
\| \phi_N^r - \phi_{N-1}^r \|_{\mathcal{W}^{2,p}(\Omega)} \leq C (\| \nabla \cdot (\epsilon (F - I) \nabla (\phi_N^r - \phi_{N-1}^r) \|_{L^p(\Omega)} + \| \phi_N^r - \phi_{N-1}^r \|_{L^p(\Omega)})
\]

\[
\leq C (\| \nabla \cdot (\epsilon (F - I) \nabla (\phi_N^r - \phi_{N-1}^r) \|_{L^p(\Omega)},
\]

\[
\leq C (\| F - I \|_{W^{1,p}(\Omega)} \| \phi_N^r - \phi_{N-2}^r \|_{\mathcal{W}^{2,p}(\Omega)},
\]

(4.25)

where in the second inequality we applied Lemma (4.5) to the problem for \( (\phi_N^r - \phi_{N-1}^r) \), and the generic constant \( C \) is independent of \( N, F \). Therefore if the constant \( C_f \) in the assumption of the theorem is chosen such that \( CC_f = k < 1 \) then \( \| \phi_N^r - \phi_{N-1}^r \|_{\mathcal{W}^{2,p}(\Omega)} \) is decreasing with respect to \( N \) hence the sequence \( \phi_N^r \) converges to a unique element \( \phi^r \) in \( \mathcal{W}^{2,p}(\Omega) \). Letting \( N \to \infty \) we can observe that \( \phi^r \) is the unique solution of problem (4.16), meaning \( \phi^r = \phi^r \).

The estimate of \( \phi^r \) is obtained by estimating \( \phi_N^r \) and passing \( N \) to \( \infty \). We notice that \( \phi_N^r = \phi_N^r - \phi_{N-1}^r + \phi_{N-1}^r - \phi_{N-2}^r + \cdots + \phi_0^r \), hence

\[
\| \phi_N^r \|_{\mathcal{W}^{2,p}} \leq \frac{1 - k^N}{1 - k} \| \phi_0^r - \phi_{N-1}^r \|_{\mathcal{W}^{2,p}} + \| \phi_0^r \|_{\mathcal{W}^{2,p}}
\]

\[
\leq C_2 (\| G \|_{L^p(\Omega)}) + \| g - G \|_{W^{1-1/p,p}(\Omega)} + \| \nabla G \|_{W^{1-1/p,p}(\Gamma)} \text{ as } N \to \infty,
\]

where both Theorem (2.2) and Lemma (4.5) are applied to the problem of \( \phi_N^r - \phi_0^r \) and the problem of \( \phi_0^r \) to get the desired bounds with respect to the \( \mathcal{W}^{2,p} \) and \( L^\infty \) norms, and \( C_2 \) absorbs \( k \) and all the generic constants involved in these bounds.

4.4. **Regularity and estimates for the regular nonlinear solution component \( \phi^r \).** For the nonlinear Poisson-Boltzmann equation, the regular component \( \phi^r \) of its potential solution solves

\[
- \nabla \cdot (\epsilon F \nabla \phi^r) + \int k^2 \sinh(\phi^r + G) = \nabla \cdot ((\epsilon - \epsilon_m)F \nabla G) \text{ in } \Omega
\]

\[
[\phi^r] = 0, \text{ on } \Gamma
\]

\[
\phi^r = g - G \text{ on } \partial \Omega.
\]

The appearance of the nonlinear function \( \sinh(x) \) complicates the establishment of the existence of \( \phi^r \). In particular, the Lax–Milgram Theorem is not applicable to problem (4.26). Instead we define a energy functional based on the weak formulation of (4.26) and show that the unique minimizer of this energy functional is the unique solution of
On the other hand, the establishment of the regularity and $W^{2,p}$ estimate of $\phi^r$ for (4.26) is simplified thanks to Theorem (4.4).

We start with the weak formulation of (4.26):

Find $\phi^r \in M \equiv \{ v \in H^1(\Omega) | e^v, e^{v^-} \in L^2(\Omega), \text{ and } v = g - G \text{ on } \partial \Omega \}$, such that

$$A(\phi^r, v) + (B(\phi^r), v) + \langle f_G, v \rangle = 0, \forall v \in H^1_0(\Omega),$$

(4.27)

where

$$A(\phi^r, v) = (\epsilon \nabla \phi^r, \nabla v), \quad (B(\phi^r), v) = (J\kappa^2 \sinh(\phi^r + G), v),$$

$$\langle f_G, v \rangle = \int_{\Omega} (\epsilon - \epsilon_m) F \nabla G \cdot \nabla v.$$  

We also use $f_G$ to denote the function $[\epsilon] F(u) \nabla G \cdot n$ on the dielectric boundary $\Gamma$, since

$$\langle f_G, v \rangle = (\epsilon - \epsilon_m) F \nabla G \cdot n,$$

(4.28)

where $[\epsilon] = \epsilon_s - \epsilon_m$ is the jump in $\epsilon$ on $\Gamma$. Based on this weak formulation we define an energy on $M$:

$$E(w) = \int_{\Omega} \frac{\epsilon}{2} F \nabla w \cdot \nabla w + J\kappa^2 \cosh(w + G) + \langle f_G, w \rangle.$$ (4.29)

The weak solution of Eq.(4.7) can be characterized as the minimizer of this energy functional. This equivalence and the existence of this minimizer are due to the following four simple lemmas. For the proof of these lemmas we refer to [2].

**Lemma 4.6.** If $u$ is the solution of the optimization problem, i.e.,

$$E(u) = \inf_{w \in M} E(w),$$

then $u$ is the solution of (4.7).

**Lemma 4.7.** Let $F(u)$ be a functional defined on $M$, if

(1) $M$ is weakly sequential compact, and

(2) $F$ is weakly lower semi-continuous on $M$,

then there exists $u \in M$ such that

$$F(u) = \inf_{w \in M} F(w).$$

**Lemma 4.8.** The following results hold true

(1) Let $V$ be a reflective Banach space. The set $M := \{ v \in V | \|v\| \leq r_0 \}$ is weakly sequential compact.

(2) if $\lim_{\|v\| \to \infty} F(v) = \infty$, then $\inf_{w \in V} F(w) = \inf_{w \in M} F(w)$

**Lemma 4.9.** If $F$ is a convex functional on a convex set $M$ and $F$ is Gâteaux differentiable, then $F$ is w.l.s.c. on $M$.

The existence and the uniqueness of the weak solution to (4.7) can be established using these lemmas. The following lemma establishes the existence of the minimizer of the energy $E(w)$.

**Theorem 4.10.** There exists a unique $u \in M \subset H^1(\Omega)$ such that

$$E(u) = \inf_{w \in M} E(w).$$
Proof. The differentiability of \( E(w) \) follows its definition. Actually we have
\[
\langle DE(u), v \rangle = A(u, v) + (B(u), v) + \langle f_G, v \rangle.
\]
The minimizer of \( E(w) \) exists if we can prove that
\begin{enumerate}
  \item \( M \) is a convex set
  \item \( E \) is convex on \( M \)
  \item \( \lim_{\|w\|_{H^1(\Omega)} \to \infty} E(w) = \infty \)
\end{enumerate}
It is easy to verify (1). The convexity of \( F \nabla w \cdot \nabla w \) follows from the fact that
\[
0 \leq F \nabla (\gamma w) \cdot \nabla (\gamma w) = \gamma^2 F \nabla w \cdot \nabla w \leq \gamma F \nabla w \cdot \nabla w
\]
for any \( 0 \leq \gamma \leq 1 \) since \( F \) is positive definite. The convexity of \( \cosh(w + G) \) follows from the convexity of \( \cosh(x) \) directly. Actually \( E(w) \) is strictly convex. To prove (3) we only need to show that
\[
E(w) \geq C(\epsilon, \kappa, F)\|w\|^2_{H^1(\Omega)} + C(G, g).
\]
We notice that \( \cosh(x) \geq 1 \) and
\[
< f_G, w > \leq \epsilon_0 \|F \nabla G\|_{L^2(\Omega)} \|\nabla w\|_{L^2(\Omega)}
\]
where the matrix norm
\[
\gamma = \|F\|_{L^2(\Omega)} = \sup_{v \in M, \|v\|_{L^2(\Omega)} = 1} \|F v\|_{L^2(\Omega)},
\]
is finite because \( F \) is continuous. Therefore
\[
E(w) \geq \frac{1}{2} \int_\Omega \epsilon F \nabla w \cdot \nabla w - |< f_G, w > | \\
\geq \frac{\gamma}{2} \left( \int_{\Omega} \epsilon_0 |\nabla w|^2 + \int_{\Omega_m} \epsilon_m |\nabla w|^2 \right) - \epsilon_0 \frac{\gamma}{2} (\|\nabla G\|^2_{L^2(\Omega_m)} + \|\nabla w\|^2_{L^2(\Omega_m)}) \\
= \frac{\gamma}{2} \int_{\Omega_m} \epsilon_m |\nabla w|^2 - \epsilon_0 \frac{\gamma}{2} \|\nabla G\|^2_{L^2(\Omega_m)} \\
\geq C(\epsilon, \gamma) \|\nabla w\|^2_{L^2(\Omega)} - \epsilon_0 \frac{\gamma}{2} \|\nabla G\|^2_{L^2(\Omega_m)}.
\]
The inequality (4.30) follows from the equivalence of \( \|\nabla w\|_{L^2(\Omega)} \) and \( \|w\|_{H^1(\Omega)} \) on set \( M \). The uniqueness of the minimizer of \( E(w) \) comes from the strict convexity of \( E \).

Theorem 4.11. There exists a unique solution \( \phi^r \) of (4.16) in \( H^1(\Omega) \). Moreover, there exist constants \( C_1, C_2 \) and \( C_3 \) such that \( \phi^r \) is bounded by
\[
\|\phi^r\|_{L^\infty(\Omega)} \leq C_1 + C_2 \|J\|_{L^\infty(\Omega)} + C_3 \|J\|_{L^\infty(\Omega)} \|F\|_{W^{1, p}(\Omega)}.
\]
Proof. The existence of the solution \( \phi^r \) in \( H^1(\Omega) \) has been proved by theorem (4.10) and its four lemmas. It remains to verify the \( L^\infty \) bounds of \( \phi^r \). Let \( \phi^r = \phi^l + \phi^n \) be decomposed into a linear component \( \phi^l \) and a nonlinear component. The linear component \( \phi^l \) satisfies Eq.(4.8). The existence of a weak solution \( \phi^l \in H^1_0(\Omega) \) follows that \( \nabla \cdot ((\epsilon - \epsilon_m) F \nabla G) \) is an operator in \( H^{-1}(\Omega) \) [8]. It is well known that in general
\[
C_1 \|\phi^l\|_{L^\infty} \leq \|\phi^l\|_{H^1} \leq C_2 (\|g - G\|_{H^{1/2}(\partial \Omega)} + \|f_G\|_{H^{1/2}(\Gamma)}).
\]
To estimate the nonlinear component we follow \[2\] and define:

\[
\alpha' = \arg \max_c \{ J \kappa^2 \sinh(c + \sup_{x \in \Omega_s} \phi^l + \sup_{x \in \Omega_s} G) \leq 0 \},
\]

\[
\beta' = \arg \min_c \{ J \kappa^2 \sinh(c + \inf_{x \in \Omega_s} \phi^l + \inf_{x \in \Omega_s} G) \geq 0 \},
\]

\[
\alpha = \min(\alpha', 0),
\]

\[
\beta = \max(\beta', 0).
\]

It follows from the monotonicity of \(\sinh(x)\) that

\[
\beta = \|\phi^l\|_{L^\infty(\Omega_s)} + \|G\|_{L^\infty(\Omega_s)}, \quad (4.33)
\]

\[
\alpha = -\beta. \quad (4.34)
\]

We will show that \(\alpha\) and \(\beta\) are the lower and upper \(L^\infty\) bounds of the nonlinear component \(\phi^n\) of the weak solution to \((4.26)\), following the similar procedure as that used in proving Lemma \((4.5)\).

Define

\[
\phi_t = \max(\phi^n - \beta, 0),
\]

then \(\text{Tr}\phi_t = 0\) since \(\phi^n \in H^1_0(\Omega)\) and \(\beta > 0\) by definition. Therefore \(\phi_t \in H^1_0(\Omega)\) and satisfies the weak formulation of Eq.\((4.9)\):

\[
(e F \nabla \phi^n, \nabla \phi_t) + (J \kappa^2 \sinh(\phi^n + \phi^l + G), \phi_t) = 0.
\]

Since \(\phi_t \geq 0\) wherever \(\phi^n \geq \beta\), we have

\[
J(u) \kappa^2 \sinh(\phi^n + \phi^l + G) \geq J(u) \kappa^2 \sinh(\beta + \inf_{x \in \Omega_s} \phi^l + \inf_{x \in \Omega_s} G) \geq 0.
\]

Therefore

\[
0 \geq (e F \nabla \phi^n, \nabla \phi_t) = (e F \nabla (\phi^n - \beta), \nabla \phi_t) = e F \nabla \phi_t \cdot \nabla \phi_t \geq 0,
\]

where the last inequality holds true since \(F\) is positive definite. Hence \(\nabla \phi_t = 0\), and \(\phi_t = 0\) or \(\phi^n \leq \beta\) in \(\Omega\) follows from the Poincare inequality. This establishes the upper bound of \(\phi^n\). By changing \(\phi_t\) to be \(\min(\phi^n + \alpha, 0)\) we can also prove that \(\alpha\) is the lower bound.

Combining the estimates for \(\phi^l\) and \(\phi^n\) we finally obtain the \(L^\infty\) estimate of the regular component \(\phi^r\):

\[
\|\phi^l + \phi^n\|_{L^\infty(\Omega)} \leq \|\phi^l\|_{L^\infty(\Omega)} + \|\phi^n\|_{L^\infty(\Omega)} \leq \|\phi^l\|_{L^\infty(\Omega)} + \|\phi^l\|_{L^\infty(\Omega_s)} + \|G\|_{L^\infty(\Omega_s)} \leq 2(C_g + C_G)\|J\|_{L^\infty(\Omega)} + C_{fg}\|F\|_{W^{1,p}(\Omega_s)}\|J\|_{L^\infty(\Omega)} + \frac{\|J\|_{L^\infty(\Omega)}NKq_{\max}}{\delta} = C_1 + C_2\|J\|_{L^\infty(\Omega)} + C_3\|J\|_{L^\infty(\Omega)}\|F\|_{W^{1,p}(\Omega_s)}. \quad \square
\]

We are now able to examine the regularity results and the estimate of \(\phi^r\) in \(W^{2,p}\).

**Theorem 4.12.** If \(\|F - I\|_{W^{1,p}(\Omega)} \leq C_f\) then the unique solution \(\phi^r\) of \((4.26)\) belongs to \(W^{2,p}(\Omega)\) and the following estimate holds

\[
\|\phi^r\|_{W^{2,p}(\Omega)} \leq C \left(\|G\|_{L^p(\Omega_s)} + \|g - G\|_{W^{2-1/p,p}(\partial \Omega)} + \|F \nabla G\|_{W^{1-1/p,p}(\Gamma)}\right). \quad (4.35)
\]
Proof. It is noticed that the problem (4.26) can be written as a form similar to its linear counterpart (4.16)
\[-\nabla \cdot (\epsilon F \nabla \phi^r) + J\kappa^2 (\phi^r + G) = \nabla \cdot ((\epsilon - \epsilon_m) F \nabla G) - J\kappa^2 (\sinh(\phi^r + G) - (\phi^r + G)) \text{ in } \Omega\]
\[[\phi^r] = 0, \text{ on } \Gamma\]
\[\phi^r = g - G \text{ on } \partial \Omega.\]

According to Theorem (4.4), the $W^{2,p}$ regularity of $\phi^r$ directly follows from the facts that $\nabla \cdot ((\epsilon - \epsilon_m) F \nabla G)$ represents an interface condition in $W^{2-1/p,p}(\Omega)$ and that $J\kappa^2 (\sinh(\phi^r + G) - (\phi^r + G)) \in L^\infty$. In the mean time, we have an estimate
\[\|\phi^r\|_{W^{2,p}(\Omega)} \leq C \left( \|G\|_{L^p(\Omega_s)} + \|g - G\|_{W^{2-1/p,p}(\partial \Omega)} + \|F \nabla G\|_{W^{1-1/p,p}(\Gamma)} \right).\] □

5. An Electrostatic Force Model and Some Estimates

For the untransformed nonlinear Poisson-Boltzmann equation (1.2) the electrostatic energy of the system is defined [27, 13, 14] to be
\[E = \int_\Omega [\rho^f \phi - \frac{1}{2} \epsilon (\nabla \phi)^2 - \kappa^2 (\cosh(\phi) - 1) \chi] dx, \] (5.1)
where the characteristic function $\chi = 1$ in $\Omega_s$ and is 0 in molecules $\Omega_{mf}, \Omega_{mr}$. This energy is very similar to the energy functional defined in Eq.(4.29), and any potential function $\phi$ minimizing (4.29) is also the minimizer of this electrostatic energy because $\cosh(x) \geq 1$. The function $\cosh(\phi) - 1$ describes the physical fact that the total electrostatic energy is zero when $\phi$ is everywhere zero. The three terms in this energy represent three types of energy densities, namely, the Coulomb energy, the electrostatic stress energy and the osmotic stress energy of the mobile ions. Based on this energy function, the following density function of the force exerted on the molecule was derived [14] by using a variational derivation method:
\[f = \rho^f E - \frac{1}{2} |E|^2 \nabla \epsilon - \kappa^2 (\cosh(\phi) - 1) \nabla \chi, \] (5.2)
where the three terms correspond to the Coulomb force, dielectric pressure and the ionic pressure, respectively. The last two boundary forces are always in the normal direction of the molecular surface because of the gradients of $\epsilon$ and the characteristic function $\chi$. The electric force defined in (5.2) is physically justifiable, and can be converted into a form identical to the Maxwell stress tensor (MST) [13, 32]. The MST describes the volume force density in a linear dielectric, and has been widely utilized in dielectrophoretic force and electrorotational torque calculations of colloids, macromolecules and biological cells in continuous external electric field [32]. In the context of interactions between singular charges distribution and resulting singular electric field, refinements are necessary to make this force model computationally more tractable. Below we will discuss the treatments of its three components.

The first term in Eq. (5.2) might appear misleading because of the multiplication of two singular functions, $\rho^f$ and $E$, in its expression. We therefore would emphasis that at a singular change $x_i$ the electric potential field multiplied with $\rho^f$ in Eq.(5.1) shall be interpreted as the summation of reaction potential field $\phi^r$, i.e., the regular component of
the potential solution, and the Coulomb potential induced by all other singular charges [14]:

\[
\rho^f \mathbf{E} = \sum_i q_i \delta(x_i) \mathbf{E} := \sum_i q_i \delta(x_i) \nabla \left( \phi^r(x) + \sum_{j \neq i} G_j(x) \right)
\]

\[
= \sum_i q_i \nabla \left( \phi^r(x_i) + \sum_{j \neq i} G_j(x_i) \right) \delta(x_i). \quad (5.3)
\]

This verifies that the force exerted at each charged atom is finite. The eliminated term \( G_i(x_i) \) corresponds to the self-energy of the singular charges [14].

Nevertheless, the body force density \( \rho^f \mathbf{E} \) itself is still unbounded at the center of every charged atom where the charge density is singular, indicating that this body force density does not belongs to \( L^p(\Omega_{mf}) \) hence does not fit the assumption on the body force in Theorem (3.1). An alternative model is therefore necessary to regularize these singular body forces to ensure the solvability of the elasticity equation. In this study, the singular body force density is modeled by a Gaussian function

\[
f_b = \sum_i a_i e^{-\frac{(x-x_i)^2}{\sigma_i}}, \quad (5.4)
\]

where the unit normal vector is aligned with the corresponding gradient in Eq.(5.3); the decay parameter \( \sigma_i \) is chosen such that

\[
\sum_i a_i e^{-R_i^2/\sigma_i} = \delta \quad (5.5)
\]

for a given sufficiently small number \( \delta \), and \( R_i \) is the van der Waals’ radius of atom \( i \). This means that the Gaussian function is essentially compact supported in its associated atom. The prefactor \( a_i \) is determined by the conservation of force in each atom:

\[
\int_{x-x_i \leq R_i} a_i e^{-\frac{(x-x_i)^2}{\sigma_i}} dx = q_i [\phi^r(x_i) + \sum_{j \neq i} G_j(x_i)] = 4\pi a_i \int_{0}^{R_i} r^2 e^{-r^2/\sigma_i} dr. \quad (5.6)
\]

The body force \( f_b \) modeled by this Gaussian is uniformly continuous in \( \Omega_{mf} \) and belongs to \( L^p(\Omega_{mf}) \) for any \( p > 0 \). Moreover, the lemma below proves that the difference of two continuous body force densities also belongs to \( L^p(\Omega_{mf}) \), and is small if the difference between two total body forces which they approximate is small.

**Lemma 5.1.** Let \( A_1, A_2 \) be two given numbers and \( |A_1| \leq P, |A_2| \leq P \) for some \( P \). Let

\[
f_j = a_j e^{-\frac{(x-x_0)^2}{\sigma_j}} \quad \text{such that} \quad \int_{x-x_0 \leq R} a_j e^{-\frac{(x-x_0)^2}{\sigma_j}} dx = A_j \quad \text{for} \quad j = 1, 2,
\]

where \( a_j, \sigma_j \) are determined from Eqs.(5.6,5.5) for the same atom centered at \( x_0 \) and of radius \( R \). Then if \( |A_1 - A_2| \leq \delta' \) for some \( \delta' > 0 \), we have

\[
\int_{x-x_0 \leq R} |f_1 - f_2|^p dx \leq C\delta'
\]

for some constant \( C \) depending only on \( R \) and \( P \).

**Proof.** The prefactor \( a \) and the decay rate \( \sigma \) are uniformly continuous functions of \( A \) for \( |A| \leq P \) if

\[
f = a e^{-\frac{(x-x_0)^2}{\sigma}}
\]
is the approximation of \( A \) as defined by the lemma. But then there exists a constant \( C \)
depending on the derivatives of \( a \) and \( \sigma \) with respect to \( A \) such that \( |f_1(x) - f_2(x)| \leq C\delta' \)
if \( |A_1 - A_2| \leq \delta' \). The conclusion of the lemma follows directly.

The last two terms in Eq.(5.2) represent the electrostatic surface forces on the molecule. It is worth noting that the second term is not well defined and is computationally intractable if there is no dielectric boundary smoothing, due to the discontinuous electric field \( E \) on the molecular surface indicated by the interface condition

\[
\epsilon_m \nabla \phi_m \cdot \mathbf{n} = \epsilon_s \nabla \phi_s \cdot \mathbf{n} \quad \text{or} \quad \epsilon_m E_m \cdot \mathbf{n} = \epsilon_s E_s \cdot \mathbf{n}.
\]

To remove this ambiguity we consider a infinitesimal displacement \( h \) of the molecular surface in its out normal direction, see Fig.(2). The change of the electrostatic stress energy due to this small displacement is the work done by the dielectric pressure along this displacement:

\[
\int_{\Omega_s' + \Omega_m'} -\frac{1}{2} \epsilon |E|^2 d\mathbf{x} - \int_{\Omega_s + \Omega_m} -\frac{1}{2} \epsilon |E|^2 d\mathbf{x} = \int_{\Gamma_f \times h} -\frac{1}{2} (\epsilon_s |E_s|^2 - \epsilon_m |E_m|^2) d\mathbf{x} = h \int_{\Gamma_f} f_s d\mathbf{s}.
\]

This suggests the dielectric force density \( f_s \) is essentially the difference between \(-\frac{1}{2} \epsilon_s |E_s|^2\) and \(-\frac{1}{2} \epsilon_m |E_m|^2\) on the dielectric interface, i.e.,

\[
f_e = -\frac{1}{2} (\epsilon_s |E_s|^2 - \epsilon_m |E_m|^2) \mathbf{n}. \quad \text{(5.8)}
\]

By combining definitions (5.2), (5.4) and (5.8) we would obtain a complete model of the electrostatic body force and surface force:

\[
\begin{align*}
\mathbf{f}_b &= \sum_i a_i e^{-(x-x_i)^2/\sigma_i} \mathbf{n}_i, \\
\mathbf{f}_s &= -\frac{1}{2} (\epsilon_s |E_s|^2 - \epsilon_m |E_m|^2) \mathbf{n} - \kappa^2 (\cosh(\phi) - 1) \mathbf{n}. \quad \text{(5.9)}
\end{align*}
\]

**Remark 5.2.** In the sequel we will estimate the term \( ||\mathbf{f}_s||_{W^{1/2,p}(\Gamma_f)} \). Although the term \( ||E_s||_{W^{1/2,p}(\Gamma_f)} \) can be directly related to \( ||\phi_m||_{W^{2,p}(\Omega_s)} \) since the latter term is bounded in \( \Omega_s \), one cannot estimate \( ||E_m||_{W^{1/2,p}(\Gamma_f)} \) similarly by relating it with \( ||\phi_m||_{W^{2,p}(\Omega_m)} \) because \( \phi_m \) contains singularities and hence is unbounded in \( \Omega_m \). Instead we follow the procedure in the proof of (e,f) in Lemma (4.2) and eventually estimate this trace norm of \( E \) in \( \Gamma^- \) which does not contain potential singularities; the details are omitted due to similarity of these two proofs.

**Remark 5.3.** The surface force definition presented in Eq.(5.10) applies only to the discontinuous dielectric model as adopted in this study. In the continuous dielectric models, which are also widely used for in the implicit solvent simulations, different surface force definition will be derived [10]. However, the analysis on the electrostatic forces given in the below is also applicable to general surface force function \( f_s = f_s(E_s, E_m, \phi) \), and might be simplified if electrical field \( E \) is continuous, i.e., \( \epsilon \) is continuous on \( \Gamma \).

The electrostatic forces defined in Eq.(5.9) and Eq.(5.10) are also subject to the Piola transformation. Moreover these forces can not be directly supplied to the elasticity equation; only the forces relative to a reference state can be supplied. This is because a molecule is in an equilibrium state and has no elastic deformation if the electrostatic potential is induced only by the molecule itself and the solvent with physiological ionic
Figure 2. Displacement of the molecular surface $\Gamma_{f}$. The solid black line is the surface before displacement and the dashed red line is the surface after displacement. The new solvent region $\Omega_s'$ is $\Omega_s$ plus the strip between two surfaces; The strip subtracted from $\Omega_m$ the equals the new solute region $\Omega_m'$.

strength, in the absence of interactions with other molecules. We refer to this state as the free state and use it as the reference state. The net body force or the net surface force is therefore defined to be the difference between that for a molecule in non-free state and that for the same molecule in the free state. To abuse the notation these differences are still referred to as the body force and the surface force, and are denoted by $f_b$ and $f_s$ respectively:

\[
\begin{align*}
  f_b & := f_b - f_{b0} \\
  f_s & := f_s - f_{s0}
\end{align*}
\]

where $f_{b0}$ and $f_{s0}$ are the body force and the surface force in the free state, and are constant vector fields for any given macromolecule.

Physically, these two forces $f_b$ and $f_s$ shall be vanishing if there is no change of ionic strength and no additional molecules present, and will be small for small change of ionic strength and weakly interacting additional molecules. To reflect this physical reality and to facilitate the mathematical analysis, we decompose (into four steps) the transition from the original single deformable molecule immersed in aqueous solvent with physiological ionic strength to the final system with added rigid molecules, varied ionic strength and deformed molecules. In the first step, we change only the solvent from physiological ionic strength to the target strength, and assume that the molecule $\Omega_{mf}$ does not have a conformational change although the net electrostatic force is not zero due to this change of ionic strength. The electrostatic potential and forces at the end of the first perturbation are denoted by $\phi_1$ and $f_{b1}, f_{s1}$, respectively. In the second step, we alter the dielectric constant in the smooth domain $\Omega_{mr}$ from $\epsilon_s$ to $\epsilon_m$. This low dielectric space represents the empty interior of the added molecules. The electrostatic potential and forces after the second step are respectively denoted by $\phi_2$ and $f_{b2}, f_{s2}$. In the third step we place the singular charges into $\Omega_{mr}$ and define the electrostatic potential and forces to be $\phi_3$ and $f_{b3}, f_{s3}$. In the last step we allow the Poisson-Boltzmann equation to couple with the elastic deformation so that the system will arrive at the final state with electrostatic potential $\phi$ and forces $f_b, f_s$. We write the net body force $f_b$ and the net surface force as the summation of their four components

\[
\begin{align*}
  f_b & = (f_b - f_{b3}) + (f_{b3} - f_{b2}) + (f_{b2} - f_{b1}) + (f_{b1} - f_{b0}) \\
  f_s & = (f_s - f_{s3}) + (f_{s3} - f_{s2}) + (f_{s2} - f_{s1}) + (f_{s1} - f_{s0})
\end{align*}
\]
corresponding to the above decomposition, and estimate these components individually.

5.1. The surface force due to changing ionic strength. The electrostatic potential \( \phi_0 \) of the system in the free state is given by

\[
- \nabla \cdot (\varepsilon \nabla \phi_0) + \kappa_0^2 \sinh(\phi_0) = \sum_{i} q_i \delta(x - x_i), \tag{5.15}
\]

while the electrostatic potential \( \phi_1 \) after changing of the ionic strength satisfies

\[
- \nabla \cdot (\varepsilon \nabla \phi_1) + \kappa^2 \sinh(\phi_1) = \sum_{i} q_i \delta(x - x_i). \tag{5.16}
\]

By subtracting Eq.(5.15) from Eq.(5.16) we get

\[
- \nabla \cdot (\varepsilon \nabla \tilde{\phi}) + (\kappa^2 - \kappa_0^2) \cosh(\xi) \tilde{\phi} = (\kappa_0^2 - \kappa^2) \sinh(\phi_0) \text{ in } \Omega, \tag{5.17}
\]

where \( \tilde{\phi} = \phi_1 - \phi_0 \) and \( \xi(x) \in (\min\{\phi_1(x), \phi_0(x)\}, \max\{\phi_1(x), \phi_0(x)\}) \) is a function between \( \phi_1 \) and \( \phi_0 \) satisfying the Cauchy mean value theorem

\[
\sinh(\phi_1) = \sinh(\phi_0) + \cosh(\xi)(\phi_1 - \phi_0).
\]

We note that the singular charges disappear in Eq.(5.17), and hence \( \tilde{\phi} \in H^1(\Omega) \) and is also in \( C^\infty \) in \( \Omega_{mf} \) and \( \Omega_\cap \Omega_{mf} \). Moreover, following Theorem (2.2) we have the following \( W^{2,p} \) estimate for \( \tilde{\phi} \):

\[
\| \tilde{\phi} \|_{W^{2,p}(\Omega)} \leq C\left( \| \tilde{\phi} \|_{L^p(\Omega)} + \| (\kappa_0^2 - \kappa^2) \sinh(\phi_0) \|_{L^p(\Omega)} + \| \tilde{G} \|_{L^p(\partial \Omega)} \right), \tag{5.18}
\]

where

\[
\tilde{G} = \sum_{i} \frac{e^{-\kappa|x-x_i|} - e^{-\kappa_0|x-x_i|}}{\varepsilon_w|x - x_i|} \approx -(\kappa - \kappa_0) \sum_{i} \frac{e^{-\kappa|x-x_i|}}{\varepsilon_w}, \tag{5.19}
\]

is the boundary condition of \( \tilde{\phi} \) on \( \partial \Omega \), and is the difference of boundary values of \( \phi_1 \) and \( \phi_0 \). The approximation in Eq.(5.19) is well defined for small \( (\kappa - \kappa_0) \). On the other hand, Lemma (4.5) says that \( \| \tilde{\phi} \|_{L^p(\Omega)} \) itself can be estimate by

\[
\| \tilde{\phi} \|_{L^p(\Omega)} \leq C \| \phi_1 - \phi_0 \|_{L^p(\Omega)} \leq C \left( \| (\kappa_0^2 - \kappa^2) \sinh(\phi_0) \|_{L^2(\Omega)} + \| \tilde{G} \|_{H^{1/2}(\partial \Omega)} \right). \tag{5.20}
\]

By combining Eqs. (5.18), (5.19) and (5.20) we get

\[
\| \phi_1 - \phi_0 \|_{W^{2,p}(\Omega)} \leq C |\kappa_0 - \kappa| \tag{5.21}
\]

We now proceed to estimate the changes of electrostatic forces \( f_{b1} - f_{b0}, f_{s1} - f_{s0} \). The body force change

\[
\| f_{b1} - f_{b0} \|_{L^p(\Omega_{mf})} \leq C \sum_i \| \tilde{\phi}(x_i) \| \leq C |\kappa_0 - \kappa| \tag{5.22}
\]

We now proceed to estimate the changes of body force change.
follows from Lemma \((5.1)\). On the other hand,
\[
\begin{align*}
f_{s1} - f_{s0} &= \frac{1}{2}\epsilon_s(|\nabla \phi_{1s}|^2 - |\nabla \phi_{0s}|^2)n + \frac{1}{2}\epsilon_m(|\nabla \phi_{1m}|^2 - |\nabla \phi_{0m}|^2)n \\
&\quad- (\kappa^2(cosh(\phi_{1s}) - 1) - \kappa_0^2(cosh(\phi_{0s}) - 1)) n \\
&= \frac{1}{2}\epsilon_s(\nabla \phi_{1s} - \nabla \phi_{0s}) \cdot (\nabla \phi_{1s} + \nabla \phi_{0s})n \\
&\quad+ \frac{1}{2}\epsilon_m(\nabla \phi_{1m} - \nabla \phi_{0m}) \cdot (\nabla \phi_{1m} + \nabla \phi_{0m})n \\
&\quad- \kappa^2(cosh(\phi_{1s}) - cosh(\phi_{0s}))n \\
&\quad- (\kappa^2 - \kappa_0^2)cosh(\phi_{0s})n \\
&\quad- (\kappa^2 - \kappa_0^2).
\end{align*}
\]

We note that with the mean value theorem, \(\kappa^2(cosh(\phi_{1s}) - \kappa^2 cosh(\phi_{0s}))\) can be related to the change of ionic strength as
\[
\kappa^2(cosh(\phi_{1s}) - cosh(\phi_{0s})) = \kappa^2 \sinh(\xi')(\phi_{1s} - \phi_{0s}).
\]

Moreover, we can not bound the trace norm of \(|\nabla \phi_{1m}|^2 - |\nabla \phi_{0m}|^2|\) by its Sobolev norm in subdomain \(\Omega_{m\text{f}}\) where the singularities of the potential are located. Instead we follow the remark of Eq. \(5.10\) and estimate this term in subdomain \(\Omega_{s}\). Thus the surface force change in the first perturbation step can be estimated as
\[
\|f_{s1} - f_{s0}\|_{W^{1-1/p,p}(\Gamma_f)} \leq C\left(\|\phi_1 - \phi_0\|_{W^{2,p}(\Omega_s)}\|\phi_1 + \phi_0\|_{W^{2,p}(\Omega_s)} \\
+ \|\phi_1 - \phi_0\|_{W^{2,p}(\Omega_{s*})}\|\phi_1 + \phi_0\|_{W^{2,p}(\Omega_{s*})} \\
+ \kappa^2|\sinh(\xi')|\|\phi_1 - \phi_0\|_{W^{1,p}(\Omega_s)} \\
+ |\kappa^2 - \kappa_0^2|\|\phi_{0s}\|_{W^{1,p}(\Omega_s)} + |\kappa^2 - \kappa_0^2|\right)
\]
\[
\leq C|\kappa - \kappa_0|\left(\|\phi_1 + \phi_0\|_{W^{1,p}(\Omega_s)} + \|\phi_1 + \phi_0\|_{W^{1,p}(\Omega_{s*})} \\
+ \kappa^2|\sinh(\xi')| + (\kappa + \kappa_0)(\|\phi_0\|_{W^{1,p}(\Omega_s)} + 1)\right)
\]
\[
\leq C_s(\kappa)|\kappa - \kappa_0|, \quad (5.23)
\]

where Lemma \((2.1)\) is applied to estimate the norm of the products of two \(W^{1,p}\) functions \(\nabla \phi_1 - \nabla \phi_0\) and \(\nabla \phi_1 + \nabla \phi_0\).

5.2. The surface force due to adding a low dielectric constant cavity. Although the variation of ionic strength will change the electrostatic potential of the system, the magnitude of potential change is usually smaller than that induced by adding molecules to the system. By adding molecules to the system we will not only have the additional singular charges but also expand a cavity of low dielectric constant in the solvent. These two effects will be considered separately, and this subsection estimates only the change of potential and forces due to the additional cavity of low dielectric constant. The effect of added charges will be analyzed in the next subsection.

The electrostatic potential \(\phi_2\) with an additional low dielectric cavity in the domain is described by
\[
- \nabla \cdot (\epsilon \nabla \phi_2) + \kappa^2 \sinh(\phi_2) = \sum_{i} q_i \delta(x - x_i) \quad (5.24)
\]
A NONLINEAR ELASTICITY MODEL OF CONFORMATIONAL CHANGE

\[ \Omega \]

**Figure 3.** Illustration of adding rigid molecule(s). Left: Before adding rigid molecules the domain \( \Omega_{mr} \) is occupied by solvent and hence has dielectric constant \( \epsilon_s \). Right: After adding molecules the domain \( \Omega_{mr} \) has low dielectric constant \( \epsilon_m \).

with the same boundary conditions as Eq.(5.16). Here the dielectric constant \( \epsilon \) and ionic strength \( \kappa \) are different from those in Eq.(5.16), and thus the subtraction of Eq.(5.16) from Eq.(5.24) shall be individually conducted in \( \Omega_{mf}, \Omega_{mr} \) and \( \Omega_s \) to give the following three equations:

\[ -\nabla \cdot (\epsilon_m \nabla (\phi_2 - \phi_1)) = 0 \text{ in } \Omega_{mf}, \]
\[ -\nabla \cdot (\epsilon_s \nabla (\phi_2 - \phi_1)) + \kappa^2 (\sinh(\phi_2) - \sinh(\phi_1)) = 0 \text{ in } \Omega_s, \]
\[ -\nabla \cdot (\epsilon_m \nabla \phi_2) + \nabla(\epsilon_s \nabla \phi_1) - \kappa^2 \sinh(\phi_1) = 0 \text{ in } \Omega_{mr}. \]

By assembling these three equations we get a complete equation for \( \tilde{\phi} = \phi_2 - \phi_1 \) in \( \Omega \):

\[ -\nabla \cdot (\epsilon \nabla \tilde{\phi}) + \kappa^2 (\sinh(\phi_2) - \sinh(\phi_1)) = \frac{\epsilon_m \kappa^2 \sinh(\phi_1)}{\epsilon_s}, \quad (5.25) \]

where \( \epsilon \) is the same as that in Eq.(5.24), and the right-hand side is vanishing in \( \Omega_s \) and \( \Omega_{mf} \). This function (non-vanishing only in \( \Omega_{mr} \)) is equivalent to \(-\nabla \cdot ((\epsilon_s - \epsilon_m) \nabla \phi_1) + \kappa^2 \sinh(\phi_1)\) since

\[ -\nabla \cdot (\epsilon_s \nabla \phi_1) + \kappa^2 \sinh(\phi_1) = 0 \text{ in } \Omega_{mr}. \]

As before we notice that \( \kappa^2 (\sinh(\phi_2) - \sinh(\phi_1)) \) can be related to \( \cosh(\xi) \tilde{\phi} \) with a smooth function \( \xi \) bounded by \( \phi_1 \) and \( \phi_2 \), and therefore \( \tilde{\phi} \) in Eq.(5.25) satisfies an estimate of the form

\[ \| \tilde{\phi} \|_{W^{2,p}(\Omega)} \leq C \left( \| \tilde{\phi} \|_{L^p(\Omega)} + \| \frac{\epsilon_m}{\epsilon_s} \kappa^2 \sinh(\phi_1) \|_{L^p(\Omega_{mr})} \right) \]
\[ \leq C \| \sinh(\phi_1) \|_{L^p(\Omega_{mr})} \]
\[ \leq C \| \sinh(\phi_1) \|_{L^\infty(\Omega)} \cdot V_{mr} \]

which follows from Theorem (4.4) and Lemma (4.5), considering that Eq.(5.24) has a vanishing boundary condition. Here \( V_{mr} \) is the volume of \( \Omega_{mr} \), suggesting that \( \| \tilde{\phi} \|_{W^{2,p}(\Omega)} \) can be made arbitrarily small by reducing the volume of \( \Omega_{mr} \).

The change electrostatic body force induced by this additional low dielectric cavity can be estimated as

\[ \| f_{b2} - f_{b1} \|_{L^p(\Omega_{mf})} \leq C \sum_i |\tilde{\phi}(x_i)| \leq CV_{mr}. \quad (5.26) \]
The surface force change is
\[
f_{s2} - f_{s1} = -\frac{1}{2} \epsilon_s (|\nabla \phi_{2s}|^2 - |\nabla \phi_{1s}|^2) n + \frac{1}{2} \epsilon_m (|\nabla \phi_{2m}|^2 - |\nabla \phi_{1m}|^2) n
- \kappa^2 (\cosh(\phi_{2s}) - \cosh(\phi_{1s})) n
= -\frac{1}{2} \epsilon_s (\nabla \phi_{2s} - \nabla \phi_{1s}) \cdot (\nabla \phi_{2s} + \nabla \phi_{1s}) n
+ \frac{1}{2} \epsilon_m (\nabla \phi_{2m} - \nabla \phi_{1m}) \cdot (\nabla \phi_{2m} + \nabla \phi_{1m}) n
- \kappa^2 (\cosh(\phi_{2s}) - \cosh(\phi_{1s})) n,
\]
and thus can be estimated by
\[
\|f_{s2} - f_{s1}\|_{W^{1,1/p,p}(\Gamma_f)} \leq C \left( \|\phi_2 - \phi_1\|_{W^{1,p}(\Omega_s)} \|\phi_2 + \phi_1\|_{W^{1,p}(\Omega_s)} + \|\phi_2 - \phi_1\|_{W^{1,p}(\Omega_s^c)} \|\phi_2 + \phi_1\|_{W^{1,p}(\Omega_s^c)} + \kappa^2 |\sinh(\xi)| \|\phi_2 - \phi_1\|_{W^{1,p}(\Omega_s)} \right)
\leq C \|\phi_2 - \phi_1\|_{W^{2,p}(\Omega)} \leq C \cdot V_{mr},
\]
following from the similar arguments in last subsection for estimating \(f_{s1} - f_{s0}\).

5.3. The surface force due to additional singular charges. In this subsection we will consider the change of electrostatic potential and force caused by singular charges placed in the low dielectric space \(\Omega_{mr}\). The low dielectric space \(\Omega_{mr}\) with these charges completely models the rigid molecule which is expected to interact with a flexible molecule \(\Omega_{mf}\). The electrostatic potential field after this third perturbation step satisfies the following equation
\[
- \nabla \cdot (\epsilon \nabla \tilde{\phi}) + \kappa^2 \sinh(\phi_3) = \sum_{i}^{N_f} q_i \delta(x_i) + \sum_{j}^{N_r} q_j \delta(x_j),
\]
while the change of potential, \(\tilde{\phi} = \phi_3 - \phi_2\) is the solution of the equation
\[
- \nabla \cdot (\epsilon \nabla \tilde{\phi}) + \kappa^2 \cosh(\xi) \tilde{\phi} = \sum_{j}^{N_r} q_j \delta(x_j),
\]
which is obtained by subtracting Eq.(5.24) from Eq.(5.28). Here \(\xi(x)\) is a smooth function defined by the mean value expansion \(\sinh(\phi_3) = \sinh(\phi_2) + \cosh(\xi)(\phi_3 - \phi_2)\). To facilitate the regularity analysis of \(\tilde{\phi}\) we define its singular component \(\tilde{G}\), which solves
\[
- \nabla \cdot (\epsilon_m \nabla \tilde{G}) = \sum_{j}^{N_r} q_j \delta(x_j)
\]
and its regular component \(\tilde{G}^r\), which is the solution of
\[
- \nabla \cdot (\epsilon \nabla \tilde{G}^r) + \kappa^2 \cosh(\xi) \tilde{G}^r = \nabla \cdot ((\epsilon - \epsilon_m) \nabla \tilde{G}) - \kappa^2 \cosh(\xi) \tilde{G}.
\]
It shall be noted that \(\nabla \cdot ((\epsilon - \epsilon_m) \nabla \tilde{G})\) is nonzero only on the molecular surfaces \(\Gamma_f\) and \(\Gamma_r\), and can be represented as an interface condition \((\epsilon_s - \epsilon_m) \nabla \tilde{G} \cdot n\) on each of these two molecular surfaces similar to that in Eq.(4.28). We notice that
\[
\tilde{G}(x) = \sum_{j}^{N_r} \frac{q_j}{\epsilon_m |x - x_j|}
\]
and is of $C^\infty$ wherever away from any of $x_j$, hence of $C^\infty(\Omega)$, and thus so is $-(\epsilon_s - \epsilon_m)\nabla \tilde{G} \cdot \mathbf{n}$ on $\Gamma_f$ and $\Gamma_r$. The $W^{2,p}$ estimate of $\tilde{\phi}$ in $\Omega$ says that

$$
\|\tilde{\phi}\|_{W^{2,p}(\Omega)} \leq C \left( \|\nabla \phi\|^\prime_{L^p(\Omega)} + \|\nabla \phi\|_{L^p(\Omega)} \right)
$$

where

$$
g = \sum_{j=1}^{N_r} q_j e^{-k|x-x_j|} \text{ on } \partial\Omega
$$

is the boundary condition of Eq.(5.29), and is the difference of boundary conditions of Eq.(5.24) and Eq.(5.28).

We now analyze the change of the electrostatic forces due to the inclusion of additional singular charges. For body force we have

$$
\|f_{bi} - f_{b2}\|_{L^p(\Omega_{m_f})} \leq C \left( \sum_i |\tilde{\phi}(x_i) + \sum_{j \neq i} \tilde{G}_j(x_i)| \right) \to 0 \text{ as } q_j \to 0,
$$

and for the surface force we know

$$
f_{s3} - f_{s2} = -\frac{1}{2} \epsilon_s (|\nabla \phi_{3s}|^2 - |\nabla \phi_{2s}|^2) \mathbf{n} + \frac{1}{2} \epsilon_m (|\nabla \phi_{3m}|^2 - |\nabla \phi_{2m}|^2) \mathbf{n}
$$

This surface force difference can then be estimated by

$$
\|f_{s3} - f_{s2}\|_{W^{1,1/p,p}(\Gamma_f)} \leq C \left( \|\phi_{3s} - \phi_{2s}\|_{W^{2,p}(\Omega)} \|\phi_{3s} + \phi_{2s}\|_{W^{2,p}(\Omega)} + \|\phi_{3m} - \phi_{2m}\|_{W^{2,p}(\Omega)} \|\phi_{3m} + \phi_{2m}\|_{W^{2,p}(\Omega)} + \kappa^2 \sinh(\xi') \|\phi_{3s} - \phi_{2s}\|_{W^{2,p}(\Omega)} \right)
$$

where the constant $C$ depends on the $W^{2,p}$ norm of $\phi_2$, $\phi_3$, and therefore is bounded if $\phi_2$, $\phi_3$ are bounded.

**5.4. The surface force due to molecular conformational change.** We now consider the change of electrostatic potential and surface forces induced by elastic displacement. By subtracting Eq.(5.28) from Eq.(1.4) and with a few algebraic manipulations we get the governing equation for $\tilde{\phi} = \phi - \phi_3$:

$$
- \nabla \cdot (\epsilon \mathbf{F} \nabla \tilde{\phi}) + J \kappa^2 \cosh(\xi) \tilde{\phi} = (J - 1) \sum_i q_i \delta(x_i) + \nabla \cdot (\epsilon \mathbf{F} - 1) \nabla \phi_3
$$

$$
+ (J - 1) \kappa^2 \sinh(\phi_3),
$$

(5.36)
where the function $\xi$ is defined by use of the mean value expansion $\sinh(\phi) = \sinh(\phi_3) + \cosh(\xi)(\phi - \phi_3)$. Unlike its counterparts in the analysis for the first two steps, this function $\xi$ is not piecewise smooth since $\phi^r$ of Eq.(1.4) belongs to $W^{2,r}(\Omega)$ hence is only piecewise uniformly differentiable. The resulting mean value function $\xi$ is therefore a piecewise uniformly continuous function. Because of the appearance of remaining singular charges in the right hand side of Eq.(5.36), we know that $\tilde{\phi}$ is not in $H^1$ globally. Again we employ the decomposition $\tilde{\phi} = \tilde{G}_f + \tilde{G}_r + \tilde{\phi}^r$ to separate the singular components $\tilde{G}_f, \tilde{G}_r$ and the regular component $\tilde{\phi}^r$. The first singular component $\tilde{G}_f = \sum_{j} \tilde{G}_{fj}$ is induced by all $N_f$ singular charges in $\Omega_{mf}$

$$- \nabla \cdot (\epsilon_m F \nabla \tilde{G}_f) = (J - 1) \sum_{i} q_i \delta(x_i), \quad (5.37)$$

while the second singular component $\tilde{G}_r = \sum_{j} \tilde{G}_{rj}$ is caused by all $N_r$ singular charges in $\Omega_{mr}$

$$- \nabla \cdot (\epsilon_m F \nabla \tilde{G}_r) = (J - 1) \sum_{j} q_j \delta(x_j), \quad (5.38)$$

and both singular components have estimates similar to Eqs.(4.11) and (4.12)

$$\|\tilde{G}_f\|_{L^\infty(\Omega_s)} \leq \frac{\|J - 1\|_{L^\infty(\Omega)} N_f K q_{max}}{\delta_f} \quad \text{in } \Omega_s, \quad (5.39)$$

$$\|\tilde{G}_r\|_{L^\infty(\Omega_s)} \leq \frac{\|J - 1\|_{L^\infty(\Omega)} N_r K q_{max}}{\delta_r} \quad \text{in } \Omega_s, \quad (5.40)$$

$$\|\nabla \tilde{G}_f\|_{L^\infty(\Omega_s)} \leq \frac{\|J - 1\|_{L^\infty(\Omega)} N_f K q_{max}}{\delta_f^2} \quad \text{in } \Omega_s, \quad (5.41)$$

$$\|\nabla \tilde{G}_r\|_{L^\infty(\Omega_s)} \leq \frac{\|J - 1\|_{L^\infty(\Omega)} N_r K q_{max}}{\delta_r^2} \quad \text{in } \Omega_s. \quad (5.42)$$

By subtracting the singular components $\tilde{G}_f, \tilde{G}_r$ from Eq.(5.36) we obtain an equation for the regular component

$$- \nabla \cdot (\epsilon F \nabla \tilde{\phi}^r) + J \kappa^2 \cosh(\xi) \tilde{\phi}^r = \nabla \cdot (\epsilon(F - 1) \nabla \phi_3) + (J - 1) \kappa^2 \sinh(\phi_3)$$

$$- \nabla \cdot (\epsilon - \epsilon_m) F \nabla \tilde{G}_f$$

$$- \nabla \cdot (\epsilon - \epsilon_m) F \nabla \tilde{G}_r, \quad (5.43)$$

where the last two items $\nabla \cdot ((\epsilon - \epsilon_m) F \nabla \tilde{G}_f)$ and $\nabla \cdot ((\epsilon - \epsilon_m) F \nabla \tilde{G}_r)$ prescribe two interface conditions on the molecular surfaces $\Gamma_f$ and $\Gamma_r$:

$$f_{\tilde{G}_f} = (\epsilon_s - \epsilon_m) F \nabla \tilde{G}_f \cdot \mathbf{n}, \quad (5.44)$$

$$f_{\tilde{G}_r} = (\epsilon_s - \epsilon_m) F \nabla \tilde{G}_r \cdot \mathbf{n}, \quad (5.45)$$
similar to that defined in Eq.(4.28). For the regular component $\bar{\phi}^r$, Theorem (4.4) states that it can be estimated with respect to the $W^{2,p}$ norm as follows

$$\|\bar{\phi}^r\|_{W^{2,p}(\Omega)} \leq C \left( \|\bar{\phi}^r\|_{L^p(\Omega)} + \|f_{G_f}\|_{W^{1-1/p,p}(\Gamma_f)} + \|f_{G_r}\|_{W^{1-1/p,p}(\Gamma_f)} ight.$$

$$+ \|f_{G_f}\|_{W^{1-1/p,p}(\Gamma_r)} + \|f_{G_r}\|_{W^{1-1/p,p}(\Gamma_r)}$$

$$+ \|J - 1\|_p \sum_{i,j} f_{ij} \left( x_i \right) + \sum_{j} f_{rj} \left( x_i \right) \right)$$

$$\leq C \left( \|J - 1\|_p \|\phi\|_{W^{1,p}(\Omega_s)} + \|J - 1\|_p \|\phi\|_{W^{1,p}(\Omega_s)} + \|\phi\|_{W^{1,p}(\Omega_s)} \right).$$

(5.46)

(5.47)

where in the last inequality we applied the estimate in Eq.(4.15) for the interface conditions $f_{G_f}$ and $f_{G_r}$. Finally, we estimate the change of the electrostatic forces due to the elastic deformation. By definition, the body force change is attributed to the variation of regular component(reaction field) $\bar{\phi}^r$ and the variations of the the singular components(Coulomb potential field), and thus can be estimated as:

$$\|f_b - f_{b3}\|_{L^p(\Omega_{m,f})} \leq C \sum_i \left| \bar{\phi} \left( x_i \right) \right| + \sum_{j \neq i} \bar{G}_{fj} \left( x_i \right) + \sum_j \bar{G}_{rj} \left( x_i \right) \right)$$

$$\leq C \left( \|J - 1\|_p \|\phi\|_{W^{1,p}(\Omega_s)} + \|J - 1\|_p \|\phi\|_{W^{1,p}(\Omega_s)} + \|\phi\|_{W^{1,p}(\Omega_s)} \right).$$

(5.48)

The surface force change in this step is defined to be

$$f_s - f_{s3} = -\frac{1}{2} \epsilon_s \left( \nabla \phi_s \right)^2 - \left| \nabla \phi_{3s} \right|^2 \right) \n + \frac{1}{2} \epsilon_m \left( \nabla \phi_m \right)^2 - \left| \nabla \phi_{3m} \right|^2 \right) \n$$

$$\kappa^2 \cosh(\phi_s) - \kappa^2 \cosh(\phi_{3s}) \n$$

$$= -\frac{1}{2} \epsilon_s \left( \nabla \phi_s - \nabla \phi_{3s} \right) \cdot \left( \nabla \phi_s + \nabla \phi_{3s} \right) \n$$

$$+ \frac{1}{2} \epsilon_m \left( \nabla \phi_m - \nabla \phi_{3m} \right) \cdot \left( \nabla \phi_m + \nabla \phi_{3m} \right) \n$$

$$\kappa^2 \sinh(\xi') \left( \phi_s - \phi_{3s} \right) \n. \quad (5.49)$$

It follows that

$$\|f_s - f_{s3}\|_{W^{1-1/p,p}(\Gamma_f)} \leq C \left( \|\nabla \phi - \nabla \phi_s\|_{W^{1,p}(\Omega_s)} + \|\nabla \phi - \nabla \phi_{3s}\|_{W^{1,p}(\Omega_s)} \right.$$

$$\left. + \|\phi - \phi_{3s}\|_{W^{1,p}(\Omega_s)} \right). \quad (5.50)$$

To relate the estimate of $\nabla \phi - \nabla \phi_s$ to that of $\phi - \phi_3$ (the latter has already been estimated in Eq.(5.47)), we make use of the relation

$$\|\nabla \phi - \nabla \phi_3\|_{W^{1,p}(\Omega)} = \|\nabla \phi - \nabla \phi_3\|_{W^{1,p}(\Omega_s)}$$

$$\leq \|\nabla \phi - \nabla \phi_3\|_{W^{1,p}(\Omega_s)} + \|\nabla \phi_3 - \nabla \phi_3\|_{W^{1,p}(\Omega_s)}$$

$$\leq \|\nabla \phi - \nabla \phi_3\|_{W^{1,p}(\Omega_s)} + \|\nabla \phi - \nabla \phi_3\|_{W^{1,p}(\Omega_s)} + \|\nabla \phi - \nabla \phi_3\|_{W^{2,p}(\Omega_s)}$$

$$+ \|\nabla \phi - \nabla \phi_3\|_{W^{2,p}(\Omega_s)}$$. 

(5.51)
and a similar relation for $\|F\nabla\phi - \nabla\phi_3\|_{W^{1,p}(\Omega_f)}$. By collecting these results together we can conclude from Eq. (5.50) that

$$\|f_s - f_{s0}\|_{L^p(\Omega_{mf})} \leq C\left(\|J - 1\|_{W^{1,p}(\Omega)} + \|F - I\|_{W^{1,p}(\Omega)}\right),$$

(5.51)

which indicates the dependence and the boundedness of this electrostatic force component with respect to the elastic displacement field.

5.5. **Complete estimation of the electrostatic forces.** The complete estimation of the electrostatic surface force is presented this lemma:

**Lemma 5.4.** The electrostatic force can be made arbitrary small by reducing the variations of ionic strength, the volume of the additional low dielectric space, the added singular charge and the magnitude of the elastic deformation.

**Proof.** Following from its decomposition schemes (5.13, 5.14), the estimation of total electrostatic body force and surface force can be readily completed by combining their respective four components estimated in the four subsections above. The estimates for these two forces have an identical form

$$\|f_b - f_{b0}\|_{L^p(\Omega_{mf})} \leq C\left(\|\kappa - \kappa_0\| + \|\phi_2 - \phi_1\|_{W^{2,p}(\Omega_s)} + \|\phi_2 - \phi_1\|_{W^{2,p}(\Omega')}ight. + V_{mr} + \|F - I\|_{W^{1,p}(\Omega)} + \|J - 1\|_{W^{1,p}(\Omega)}\),$$

(5.52)

$$\|f_s - f_{s0}\|_{W^{1-1/p,p}(\Gamma_f)} \leq C\left(\|\kappa - \kappa_0\| + \|\phi_2 - \phi_1\|_{W^{2,p}(\Omega_s)} + \|\phi_2 - \phi_1\|_{W^{2,p}(\Omega')} + V_{mr} + \|F - I\|_{W^{1,p}(\Omega)} + \|J - 1\|_{W^{1,p}(\Omega)}\).$$

(5.53)

It is noticed in Eq. (5.33) that both $\|\phi_2 - \phi_1\|_{W^{2,p}(\Omega_s)}$ and $\|\phi_2 - \phi_1\|_{W^{2,p}(\Omega')}$. Moreover $F(0)(x) = 0, J(0)(x) = 1$ follow from their definitions and both functions are infinitely differentiable in the neighborhood of each function in $X_p = \{u \in W^{2,p}(\Omega_{mf}) \| \|u\|_{W^{2,p}(\Omega_{mf})} \leq M\}$. Applying the Taylor inequality we have

$$\|F - I\|_{W^{1,p}(\Omega_s)} \leq \|DF\|\|u\|_{W^{2,p}(\Omega_s)} \leq \|DJ\|\|u\|_{W^{2,p}(\Omega_s)},$$

hence the last two items in estimates (5.52, 5.53) are also small for properly chosen $X_p.$

6. **Main Results: Existence of Solutions to the Coupled System**

We now establish the main existence result in the paper. It is noticed that for every element $v \in X_p$ one can derive a Piola transformation and solve for a unique potential solution of the Poisson-Boltzmann equation with this Piola transformation. The electrostatic forces computed from this potential solution belongs to $W^{1-1/p,p}(\Gamma_f)$ hence there is also a unique solution $u$ to Eq. (3.1) corresponding to these electrostatic forces. This loop defines a map $S$ which associates every $v$ with a new displacement function $u.$ Our existence result is based on the following version of the Schauder fixed-point theorem.

**Theorem 6.1.** Let $X_p$ be a closed convex set in a Banach space $X$ and let $S$ be a continuous mapping of $X_p$ into itself such that the image of $S(X_p)$ is relatively compact. Then $S$ has a fixed-point in $X_p.$
Theorem 6.2. $S : X_p \to X_p$ is weakly continuous in $W^{2,p}(\Omega_{mf})$.

Proof. This proof follows the similar arguments in [6]. Let $v_n$ be a sequence in $X_p$ and $v_n \rightharpoonup v$ in $W^{2,p}$ as $n \to \infty$. With these displacement fields, we can compute the electrostatic potential $\phi_n = \phi(v_n)(\therefore)$ hence the electrostatic body force $f_{bn} = f_b(v_n)$ and surface force $f_{sn} = f_s(v_n)$ and new displacement fields $u_n = u(v_n)$ defining the mapping $S$. We know from (5.52), (5.53) and (3.2) that $\phi_n, f_{bn}, f_{sn}$ and $u_n$ are bounded independently of $n$. Therefore there exists a subsequence $v_{n_l} \subset v_n$, an electrostatic potential $\bar{\phi}$, and a displacement field $\bar{u}$, such that

$$\phi(v_{n_l}) \rightharpoonup \bar{\phi} \text{ as } l \to \infty$$
$$u(v_{n_l}) \rightharpoonup \bar{u} \text{ as } l \to \infty$$

We shall prove that $u(v) = \bar{u}$ by investigating the limit of the equations for $\phi(v_{n_l})$ and $u(v_{n_l})$, and of the expression for $F(v_{n_l}), f_b(v_{n_l}), f_s(v_{n_l})$ and $J(v_{n_l})$. Since $\Phi(v_{n_l}) \rightharpoonup \Phi(v)$ in the weak sense as $v_{n_l} \rightharpoonup v$ and $W^{2,p}$ is compactly embedded in $C^1$, there is a subsequence of $v_{n_k} \subset v_{n_l}$ such that

$$v_{n_k} \rightharpoonup v \text{ in } C^1(\Omega) \text{ as } k \to \infty$$
$$\Phi(v_{n_k}) \rightharpoonup \Phi(v) \text{ in } C^1(\Omega) \text{ as } k \to \infty;$$

and hence

$$J(v_{n_k}) \rightharpoonup J(v) \text{ in } C^0(\Omega) \text{ as } k \to \infty,$$

following the definition of $J(v)$. The convergence of

$$F(v_{n_k}) \rightharpoonup F(v) \text{ in } C^0(\Omega) \text{ as } k \to \infty,$$

which involves the inversion of $\nabla \Phi(v)$, is substantiated by continuous mapping from a $n \times n$ matrix to its inverse in $C^0(\Omega)$, i.e.,

$$A_{n \times n} \in C^0(\Omega) \implies A_{n \times n}^{-1} \in C^0(\Omega)$$

in the neighborhood of each invertible matrix of $C^0(\Omega)$, and by the invertibility of $\nabla \Phi(v_{n_k})$ in $W^{1,p}(\Omega)$. Now we can pass the equations satisfied by $\phi_{n_k}$ and $v_{n_k}$ to the limit and deduce that

$$\phi(v_{n_k}) \rightharpoonup \phi(v) = \bar{\phi},$$
$$u_{n_k} \rightharpoonup u(v) = \bar{u}.$$  

This proves the continuity of mapping $S$ in the weak topology of $W^{2,p}$. □ □

Finally we verify that $S(X_p) \subset X_p$. By connecting the force estimates (5.52)–(5.53) and the estimate of displacement $u$ in theorem (3.1) we observe that

$$\|u\|_{W^{2,p}} \leq C\left(\|f_b\|_{L^p(\Omega_{mf})} + \|f_s\|_{H^{1-1/p,p}(\Gamma_f)}\right)$$

$$\leq C\left(|\kappa - \kappa_0|\|\phi_2 - \phi_1\|_{W^{2,p}(\Omega_0)} + \|F - I\|_{W^{1,p}(\Omega_0)} + \|J - I\|_{L^\infty}\right)$$

$$\leq M \leq \frac{C}{\max\{C1, C2\}}$$

(6.1)
for appropriately small change in ionic strength and in the charges in the added molecules, where \( C, C_1, C_2 \) are the constants prescribed in inequality (3.5). Thus we verified that \( S(X_p) \subset X_p \) and \( \Phi(u) \) is invertible. This gives the main result in the paper as the following theorem.

**Theorem 6.3.** There exists a solution to the coupled nonlinear PDE system (3.1) and (1.4) for sufficiently small \( \kappa - \kappa_0 \) and sufficiently small rigid molecule \( \Omega_{mr} \) with sufficiently small charges.

**Proof.** This follows from Theorem 6.1 combined with Theorem 6.2. \( \Box \)

7. **Variational Principle for Existence and/or Uniqueness**

In addition to the fixed point arguments, variational principles and quasivariational inequalities are also widely used for analyzing coupled systems of PDEs arising from multiphysics modeling. While quasivariational inequalities are exclusively used for systems with boundary conditions given by inequalities, a single energy functional for the entire system is generally required for the application of either of these two approaches, and the stationary point of this energy functional with respect to each function shall produce the corresponding differential equations and all boundary conditions. This energy functional is usually given by the total potential energy of the system, or by the sum of the potential energies of each equation if these energies are compatible. While it remains challenge to construct the total energy for our problem, we can give a coupled weak form of the entire system:

\[
(Ax, y) = (f_b, v)_{L^2(\Omega_{mf})} + (f_s, v)_{L^2(\Gamma_{mf})} \forall y \in P, \quad (7.1)
\]

where \( x = (u, \phi), y = (v, \psi) \) are in the product space \( P \) of \( W^{2,p}(\Omega_{mf}) \) for the displacement field \( u \) and the \( W^{2,p}(\Omega) \) for the regular component of electrostatic potential \( \phi^r \), i.e., \( P = W^{2,p}(\Omega_{mf}) \times W^{2,p}(\Omega) \), and the operator \( A \) is defined by

\[
(Ax, y) = (T(u), E(v)) + (\epsilon F \nabla \phi, \nabla v) + (J \kappa^2 \sinh(\phi + G), \psi), \quad (7.2)
\]

where the stress tensor \( T \) and the strain tensor \( E \) were given in Eq. (1.3).

Unlike the piezoelectric problems to which variational principles and quasivariational inequalities can be readily applied, we lack the coupling of the electrostatic potential and elastic displacement at the level of constitutive relations of the material [39, 41]. Instead, our electro-elastic coupling is through the electrostatic forces. We note that variational principles have been formulated for a class of fluid-solid interaction systems [42], which resemble our problem in that the coupling is through the boundary conditions of the elasticity equation instead of the constitutive relations. This will be examined for our problem in a future work.

8. **Concluding Remarks**

In this paper we have proposed and carefully analyzed a nonlinear elasticity model of deformation in macromolecules induced by electrostatic forces. This was accomplished by coupling the nonlinear Poisson-Boltzmann equation for the electrostatic potential field to the nonlinear elasticity equations for elastic deformation. The electrostatic of this coupled system is described by an implicit solvation model, and the Piola transformation defined by the solution of the elasticity equation is introduced into the Poisson-Boltzmann equation such that both equations can be analyzed together in an undeformed configuration. A key technical tool for coupling the two models is the use of an harmonic extension
of the elastic deformation field into the solvent region of the combined domain. Combining this technical tool with regularization techniques established in [2] and a standard bootstrapping technique, we showed that the Piola-transformed Poisson-Boltzmann equation is also well-defined and the regular component of its solution has a piecewise $W^{2,p}$-regularity. This regularity matches that of the elastic deformation, giving access to a Schauder fixed-point theorem-based analysis framework for rigorously establishing the existence of solutions to this coupled nonlinear PDE system for small perturbation in the ionic strength and for small added charges. The existence of large deformation for large perturbations in ionic strength and/or charges can be obtained by combining our local result with general continuation techniques for nonlinear elastic deformation [36]. Our Schauder-type existence proof technique did not require that we establish a contraction property for the fixed-point mapping $S$; this results in losing access to a uniqueness result for the coupled system, as well losing access to a fixed error reduction property for numerical methods based on the fixed-point mapping $S$.

The coupling of elastic deformation to the electrostatic field is of great importance in modeling the conformational change in large macromolecules. To put this into perspective, more comprehensive and realistic continuum models for macromolecular conformational changes can be developed based on the results in this article, for example, by coupling the (stochastic) hydrodynamical forces from the Stokes or Navier-Stokes equation, or including van der Waals forces between closely positioned molecules. While mathematical models and robust numerical methods have been well studied for steady state fluid-structure interaction problems [6], the inclusion of van der Waals forces appears to be more straightforward [34]. A major concern in applying these coupled models, however, is the determination of the elasticity properties of macromolecules within the continuum framework, which requires new theoretical models and quantitative comparisons between the continuum modeling and the classical molecular dynamical simulation and/or experiential measurements. In a future work we will study the development of numerical methods for this coupled system and apply this model to macromolecular systems where electrostatic forces play a dominant role.
