The Brown-York mass of black holes in Warped Anti-de Sitter space

Gaston Giribet\textsuperscript{1} and Andrés Goya\textsuperscript{1,}\textsuperscript{†}

\textsuperscript{1}Physics Department, University of Buenos Aires FCEN-UBA, and IFIBA-CONICET, Ciudad Universitaria, Pabellón I, 1428, Buenos Aires, Argentina.

We give a direct computation of the mass of black holes in Warped Anti-de Sitter space (WAdS) in terms of the Brown-York stress-tensor at the boundary. This permits to explore to what extent the holographic renormalization techniques can be applied to such type of deformation of AdS. We show that, despite some components of the boundary stress-tensor diverge and resist to be regularized by the introduction of local counterterms, the precise combination that gives the quasilocal energy density yields a finite integral. The result turns out to be in agreement with previous computations of the black hole mass obtained with different approaches. This is seen to happen both in the case of Topologically Massive Gravity and of the so-called New Massive Gravity. Here, we focus our attention on the latter. We observe that, despite other conserved charges diverge in the near boundary limit, the finite part in the large radius expansion captures the physically relevant contribution. We compute the black hole angular momentum in this way and we obtain a result that is in perfect agreement with previous calculations.

I. INTRODUCTION

The idea of extending AdS/CFT correspondence to Warped AdS spaces (WAdS) has been originally proposed in Ref. \cite{1,11}. This represents one of the most appealing attempts to generalize holography to non-AdS spaces, and this is because WAdS spaces appear in several contexts. For instance, WAdS spaces provide gravity duals for condensed matter systems with Schrödinger symmetry \cite{12,13}, they are closely related to the geometry of rotating black holes \cite{14,15}, and they also appear in relation to many other interesting subjects \cite{16,18}. Asymptotically WAdS\textsubscript{3} spaces turn out to be exact solutions of String Theory \cite{19–23,24} as well as of other models of three-dimensional gravity, including Higher-Spin Gravity \cite{24}, Topologically Massive Gravity (TMG) \cite{25,26}, and New Massive Gravity (NMG) \cite{27}. Here, we will be concerned with the latter: We will consider asymptotically WAdS\textsubscript{3} black holes in NMG. For such solutions, we will give a direct computation of the mass of the Brown-York stress-tensor \cite{28} in the boundary of the space. We do this to explore to what extent the holographic renormalization techniques can be applied to such a deformation of AdS. Whether or not the Brown-York tensor can be defined at the boundary of WAdS\textsubscript{3} space is a question that has been raised, for instance, in Ref. \cite{5}. Here, we will show that, despite some components of the Brown-York stress-tensor diverge in the near boundary limit and resist to be regularized by the introduction of local counterterms, the integral of the precise combination that gives the definition of the quasilocal energy as a conserved charge yields a finite integral. The result we obtain happens to be in agreement with computations of the black hole mass obtained by different methods \cite{25,30,31}. Finiteness of the conserved charge computed in this way follows from cancellations that occur near the boundary. In contrast to the mass, in the case of the angular momentum the charge associated to it can not be regularized by the introduction of local boundary counterterms. However, the finite part in the near boundary expansion happens to capture the physically relevant information, and it is shown to exactly reproduce the black hole angular momentum.

The paper is organized as follows: In Section II, we briefly review the theory of New Massive Gravity introduced in Ref. \cite{32}. In Section III, we discuss the geometry of Warped Anti-de Sitter space and black holes that asymptote to it. In Section IV, we study boundary terms and the Brown-York stress-tensor they induce. We consider the near boundary limit of this stress-tensor and use it in Section V to calculate the mass of the Warped Anti-de Sitter black holes. That is, we compute the Brown-York quasilocal energy in the limit that the boundary tends to spatial infinity. The result we obtain is in agreement with previous computations. We also discuss the analogous computation in the case of the gravitational Chern-Simons term being added.

II. NEW MASSIVE GRAVITY

Let us begin by reviewing New Massive Gravity theory \cite{32}. The action of the theory consists of the sum of three different contributions, namely

\[ S = S_{\text{EH}} + S_{\text{NMG}} + S_{\text{B}}, \]

where the first term is the Einstein-Hilbert action with cosmological constant,

\[ S_{\text{EH}} = \frac{1}{16\pi G} \int_{\Sigma} d^{3}x \sqrt{-g} (R - 2\Lambda), \]
and the second term contains contributions of higher order,
\[ S_{\text{NMG}} = \frac{1}{16\pi G} \int \Sigma d^3x \sqrt{-g} (f^{\mu\nu} G_{\mu\nu} - \frac{1}{4} m^2 (f_{\mu\nu} f^{\mu\nu} - f^2)), \tag{3} \]
where \( G_{\mu\nu} \) is the Einstein tensor \( G_{\mu\nu} = R_{\mu\nu} - \frac{1}{2} R g_{\mu\nu} \), and field \( f_{\mu\nu} \) is a rank-two auxiliary field which, after being integrated, gives
\[ f_{\mu\nu} = \frac{2}{m^2} \left( R_{\mu\nu} - \frac{1}{2} R g_{\mu\nu} \right). \tag{4} \]

The third term in \( \Sigma \), \( S_B \), is a boundary action needed for the variational principle to be defined in a specific way. We will discuss the boundary terms later.

By reinserting (4) back in (3) the higher-curvature terms take the form
\[ S_{\text{NMG}} = \frac{1}{16\pi G m^2} \int \Sigma d^3x \sqrt{-g} \left( R_{\mu\nu} R^{\mu\nu} - \frac{3}{8} R^2 \right), \tag{5} \]
which is the form of the action presented in [32]. The equations of motion derived from action (1) read
\[ 16\pi G \frac{\delta S}{\delta g_{\mu\nu}} = G_{\mu\nu} + \Lambda g_{\mu\nu} + \frac{1}{2 m^2} K_{\mu\nu} = 0. \tag{6} \]
which, apart from the Einstein tensor \( G_{\mu\nu} \), involve the tensor
\[ K_{\mu\nu} = 2 \square R_{\mu\nu} - \frac{1}{2} \nabla_\mu \nabla_\nu R - \frac{1}{2} \square R g_{\mu\nu} + 4 R_{\mu\alpha\nu\beta} R^{\alpha\beta} - \frac{3}{2} RR_{\mu\nu} - R_{\alpha\beta} R^{\alpha\beta} g_{\mu\nu} + \frac{3}{8} R^2 g_{\mu\nu}. \tag{7} \]

The precise combination of the square-curvature terms in (5), \( g^{\mu\nu} K_{\mu\nu} = R_{\mu\nu} R^{\mu\nu} - (3/8) R^2 \), is such that the trace of the equations of motion (6) does not involve the mode \( \square R \). This is one of the reasons why NMG is free of ghosts – for instance – about flat space.

Equations of motion (6) are solved by all solutions of General Relativity, provided an adequate renormalization of the effective cosmological constant. The theory also admits solutions that are not Einstein spaces; these have \( K_{\mu\nu} \neq 0 \). Probably the simplest solutions of this sort are WAdS3 spaces.

III. WARPED ANTI-DE SITTER

A. WAdS3 space

WAdS3 spaces are squashed or stretched deformations of AdS3 [11]. Such a deformation is obtained by first writing AdS3 as a Hopf fibration of \( \mathbb{R} \) over AdS2 and then multiplying the fiber by constant warp factor \( K \). More precisely, one first considers the metric of AdS3 written in coordinates
\[ ds^2 = \frac{l^2}{4} \left( -\cosh^2 x \, dt^2 + dx^2 + (dy + \sinh x \, dt)^2 \right), \tag{8} \]
and then deforms it as follows
\[ ds^2 = \frac{l^2}{4} \left( -\cosh^2 x \, dt^2 + dx^2 + K (dy + \sinh x \, dt)^2 \right), \tag{9} \]
where \( x, y, \tau \in \mathbb{R} \), and \( K \in \mathbb{R} \). It is usual to parameterize the deformation by a positive constant \( \nu \) defined by \( K = 4\nu^2/(\nu^2 + 3) \), such that \( \nu = 1 \) corresponds to undeformed –unwarped– AdS3. Through the deformation, the AdS3 radius \( l \) gets also rescaled as \( l^2 \rightarrow l^2_k = 4l^2/(\nu^2 + 3) \). Spaces (9) with \( \nu^2 > 1 \) describe stretched AdS3 spaces, while those with \( \nu^2 < 1 \) describe squashed deformations of it. Through a double Wick rotation \( x, \tau \rightarrow ix, i\tau \) one goes from the spacelike WAdS3 metric (9) to a timelike analog of it. Here we will be involved with spacelike stretched WAdS3 spaces.

B. WAdS3/CFT2

The warping deformation breaks the \( SL(2,\mathbb{R}) \times SL(2,\mathbb{R}) \) isometry group of AdS3 space down to \( SL(2,\mathbb{R}) \times U(1) \). As a consequence, also the asymptotic isometry group, which in the case of AdS3 coincides with the two-dimensional local conformal group, gets altered. It has been recently understood that the asymptotic group of WAdS3 turns out to be generated by the semi-direct product of one copy of Virasoro algebra and an affine extension of \( u(1) \) algebra with non-vanishing central extension; see [2, 4, 8, 9]. That is, the asymptotic isometry group in WAdS3 spaces certainly differs from the two-dimensional conformal group; nevertheless, it has been shown in [11] that, under certain circumstances, the symmetry results powerful enough to constrain the dual theory and extract relevant information from it. The holographic description of WAdS3 black hole thermodynamics carried out in [11] is a notable realization of this idea.

Motivated by the similarities between asymptotically WAdS3 and asymptotically AdS3 spaces, the authors of [11] proposed the idea of extending AdS/CFT to the former case. The conjecture is that quantum gravity in asymptotically WAdS3 space would be dual to a two-dimensional theory which exhibits partial conformal symmetry, it being symmetric under right – but not left – dilations. The main motivation we have to study the holographic renormalization techniques in this context comes from trying to determine to what extent what we know about holography can be applied with no major modification to WAdS spaces as well.
C. WAdS$_3$ black holes

One of the most attractive properties of WAdS space is that it admits black holes that asymptote to it and, on the other hand, are given by discrete quotients of WAdS$_3$ itself. This is analogous to what happens with the Bañados-Teitelboim-Zanelli (BTZ) black hole [33], which is locally equivalent to AdS$_3$. The existence of WAdS$_3$ black holes is very interesting since, if thought of within the context of a WAdS$_3$/CFT$_2$ geometry (10) is constructed as a quotient of WAdS$_3$ space [1]. That is, black hole solutions [10] asymptote spacelike stretched WAdS$_3$ at large $r$. Metric (10) can also be written in the ADM like form

$$ds^2 = -N_t^2 dt^2 + \rho^2 (d\varphi + N^\varphi dt)^2 + \frac{l^2 dr^2}{4 \rho^2 N_t^2},$$

with

$$\rho^2 = \frac{r}{4} \left( (\nu^2 - 1)r + (\nu^2 + 3)(r_+ + r_-) - 4 \sqrt{r_+ r_- (\nu^2 + 3)} \right),$$

$$N_t^2 = \frac{(\nu^2 + 3)(r_+ - r_-)}{4 \rho^2},$$

$$N^\varphi = \frac{2 \nu r - \sqrt{(\nu^2 + 3) r_+ r_-}}{2 \rho^2}.$$

As mentioned, WAdS$_3$ black holes are specific identifications of the WAdS$_3$ space [1]. That is, black hole geometry [10] is constructed as a quotient of WAdS$_3$ space by a discrete subgroup of $SL(2, \mathbb{R}) \times U(1)$, identifying points of the original manifold along a direction $\partial \varphi = \pi (J_2 / \beta_3 - J_2 / \beta_3^R)$, with $J_2 \in SL(2, \mathbb{R})$ and $J_2 \in U(1)$, and $\beta_3 \in \mathbb{R}$. This allows to define the left- and right-temperature as the inverse of the periods $\beta_{3L,R}$; namely

$$T_L = \beta_{3L}^{-1} = \frac{(\nu^2 + 3)}{8 \pi l^2} (r_+ + r_- - \frac{1}{\nu} \sqrt{\nu^2 + 3} r_+ r_-),$$

$$T_R = \beta_{3R}^{-1} = \frac{(\nu^2 + 3)}{8 \pi l^2} (r_+ - r_-).$$

Because of being locally equivalent to WAdS$_3$ space [9], and despite having a richer causal structure, the local geometry of black holes [10] is remarkably simple. In particular, the curvature scalars result to be independent of the integration constants $r_{\pm}$. Moreover, all the curvature invariants turn out to be constant, given only in terms of parameters $\nu$ and $l$; for instance,

$$R = -\frac{6}{l^2}, \quad R_{\mu\nu} R^{\mu\nu} = \frac{6}{l^2} (3 - 2 \nu^2 + \nu^4),$$

$$R_{\mu\nu} R^\mu R^\nu = -\frac{6}{l^2} (9 - 9 \nu^2 + 3 \nu^4 + \nu^6).$$

As we will see, this geometric simplicity of WAdS$_3$ black holes is, paradoxically, one of the aspects that make difficult to deal with them.

D. NMG WAdS$_3$ black holes

It has been shown in [27] that WAdS$_3$ black holes [10] solve the equations of motion of NMG if the parameters satisfy the relations

$$m^2 = -\frac{(20 \nu^2 - 3)}{2 l^2}, \quad \Lambda = -\frac{m^2 (9 - 48 \nu^2 + 4 \nu^4)}{(9 - 120 \nu^2 + 400 \nu^4)}.$$  

The same type of solution for the case of NMG theory coupled to TMG was studied in Ref. [34].

Entropy of WAdS$_3$ black hole in NMG can be evaluated by means of Wald formula [34], yielding

$$S = \frac{8 \pi \nu^3}{(20 \nu^2 - 3) G} (r_+ - \frac{1}{2 \nu} \sqrt{\nu^2 + 3} r_+ r_-).$$

Remarkably, the entropy results proportional to $T_L + T_R$, which means that it admits to be written in the Cardy like form

$$S = \frac{\pi^2 l}{3} c (T_L + T_R)$$

with $c$ being independent of $r_\pm$. Then, one may identify the central charge of the dual theory to be

$$c = \frac{96 \nu^3 l}{(20 \nu^4 + 57 \nu^2 - 9) G}.$$  

Notice that, in the limit $\nu \to 1$, central charge [18] tends to its AdS$_3$ value $c = 24l/(17G)$; recall that in NMG the Brown-Henneaux central charge $3l/(2G)$ gets multiplied by a factor $1 + 1/(2 \nu^2 l^2)$, and, according to [15], $\nu = 1$ corresponds to $m^2 l^2 = -17/2$.

IV. BROWN-YORK STRESS-TENSOR

A. ADM decomposition

Now, let us analyze the definition of the Brown-York tensor in NMG. This has been originally studied in Ref.
where \( N \) is the radial lapse function, and \( \gamma_{ij} \) is the two-dimensional metric on the constant-\( r \) surfaces. The Latin indices \( i, j = 0, 1 \), refer to the coordinates on the constant-\( r \) surfaces, while the Greek indices \( \mu, \nu = 0, 1, 2 \), and include the radial direction \( r \) as well. In the case of asymptotically AdS\( 3 \) spaces, one knows how to restrict the \( r \)-dependence of \( \gamma_{ij} \) as it comes from the Fefferman-Graham expansion [36], which in three-dimensions results consistent with the Brown-Henneaux asymptotic boundary conditions [37]. For WAdS\( 3 \) the asymptotic boundary conditions were studied in Refs. [2-4, 11, 13] for the case of TMG; in particular, it has been shown in [3] that the theory admits more than one set of consistent boundary conditions, all of them being defined in a way that WAdS\( 3 \) black hole solutions \([10]\) are gathered. We assume such kind of asymptotic behavior. More precisely, we consider perturbation of the \( r_+ = r_- = 0 \) configuration \([10]\) of the form

\[
ds^2 = dt^2 + 2vrdtd\varphi + \frac{r^2dr^2}{\gamma_+^2 + \gamma_-^2} + \frac{3r^2}{4}(\nu^2-1)d\varphi^2 + h_{\mu\nu}dx^\mu dx^\nu ,
\]

(20)
gathering metrics with falling-off conditions

\[
h_{rr} \simeq \mathcal{O}(r^{-3}), \quad h_{r\varphi} \simeq \mathcal{O}(r), \quad h_{t\varphi} \simeq \mathcal{O}(1), \quad h_{tt} \simeq \mathcal{O}(r^{-3}).
\]

B. Boundary terms

Boundary terms \( S_B \) are introduced in \([11]\) for the variational principle to be defined in such a way that both the metric \( g_{\mu\nu} \) and the auxiliary field \( f_{\mu\nu} \) are fixed on the boundary \( \partial \Sigma \). With this prescription, the boundary action \( S_B \) reads

\[
S_B = -\frac{1}{8\pi G} \int_{\partial \Sigma} d^2x \sqrt{-\gamma} \left( K + \frac{1}{2} f^{ij}(K_{ij} - \gamma_{ij}K) \right).
\]

(21)

Here, \( \gamma_{ij} \) is the metric induced on \( \partial \Sigma \) and \( K_{ij} \) is the extrinsic curvature, with \( K = \gamma^{ij}K_{ij} \). On the other hand, \( f^{ij} \) in \([21]\) comes from decomposing the contravariant field \( f^{\mu\nu} \) as

\[
f^{\mu\nu} = \begin{pmatrix} f^{ij} & h^i \\ h^j & s \end{pmatrix}
\]

and defining

\[
\hat{f}^{ij} \equiv f^{ij} + 2h^iN^j + sN^iN^j, \quad \hat{f} \equiv \gamma_{ij}\hat{f}^{ij}.
\]

The first term in \([21]\) corresponds to the Gibbons-Hawking term. The other two terms come from the higher-curvature terms of NMG. Notice that in \([21]\) the field \( f^{ij} \) couples to the Israel tensor \( K_{ij} - \gamma_{ij}K \) in the same manner as the field \( f^{\mu\nu} \) couples to the Einstein tensor in the bulk action \([3]\).

Then, the Brown-York stress-tensor can be obtained by varying action \([11]\) with respect to the metric \( \gamma^{ij} \); namely

\[
T_{ij} = \frac{2}{\sqrt{-\gamma}} \frac{\delta S}{\delta \gamma^{ij}} \bigg|_{r=\text{const}}.
\]

(22)

This yields two distinct contributions, \( T^{ij} = T^{ij}_{\text{EH}} + T^{ij}_{\text{NMG}} \). First, we have the Israel term

\[
T^{ij}_{\text{EH}} = \frac{1}{8\pi G} (K^{ij} - K\gamma^{ij}),
\]

and, secondly, we have the contribution coming from the higher-curvature terms \([35]\)

\[
T^{ij}_{\text{NMG}} = -\frac{1}{8\pi G} \left( \frac{1}{2} f^{ij} K^{j\ell} + \nabla^i h^j - \frac{1}{2} \nabla_r f^{ij} + K^{ij}\nabla^k f_{jk} - 2\pi G \left( \frac{1}{2} sK^{ij} - \gamma^{ij}(\nabla_k h^i - \frac{1}{2}sK + \frac{1}{2}K - \frac{1}{2}\nabla_r f) \right) \right),
\]

where \( \hat{h}^i = N(h^i + sN^iN^j) \), \( \hat{s} = N^2s \), and where the covariant \( r \)-derivative \( \nabla_r \) is defined as follows

\[
\nabla_r f^{ij} = \frac{1}{N} \left( \partial_r \hat{f}^{ij} - N^k \partial_k \hat{f}^{ij} + 2f^{ij}(\partial_k N^j) \right),
\]

\[
\nabla_r \hat{f} = \frac{1}{N} \left( \partial_r \hat{f} - N^k \partial_k \hat{f} \right).
\]

C. Counterterms

The next step towards the definition of the boundary stress-tensor is adding counterterms to regularize \([22]\) in the limit \( r \to \infty \). In asymptotically AdS\( 3 \) space this is achieved by the holographic renormalization recipe, which amounts to add boundary terms that only involve intrinsic boundary quantities. Here, such terms would be of the form

\[
S_C = \frac{1}{8\pi G} \int_{\partial \Sigma} d^2x \sqrt{-\gamma} \left( a_0 + a_1 \hat{f} + a_2 \hat{f}^2 + b_2 \hat{f}^{ij} \hat{f}^{ij} + ... \right)
\]

(23)

The ellipses stand for higher-order intrinsic terms. From the boundary viewpoint these terms are thought of as counterterms in the dual theory; meaning that the renormalized boundary stress-tensor is defined by taking the \( r \to \infty \) limit of the improved stress-tensor

\[
T_{ij} \to T^*_{ij} = T_{ij} + \frac{2}{\sqrt{-\gamma}} \frac{\delta S_C}{\delta \gamma^{ij}}.
\]

(24)

The choice of counterterms \([23]\), namely the choice of coefficients \( a_i, b_i \), is partially determined by demanding
the action to be finite. Regarding this point, it is worthwhile mentioning a peculiarity of WAdS3 space, which is the fact that WAdS3 space does not admit a real Euclidean section. Therefore, one has to specify precisely what does requiring finiteness in the action actually mean in this context. We will circumvent the problem by saying that here we are dealing with stationary solutions, so we will demand the Lorentzian action integrated over a finite time interval to be finite. This is achieved by choosing

\[ a_0 = -\frac{8\nu^2\sqrt{\nu^2 + 3}}{(20\nu^2 - 3)t}. \]  

(25)

Nevertheless, one may ask whether (25) is the only possible choice. It turns out that the answer is in the affirmative: In contrast to what happens with other solutions of massive gravity, like the ones found in Refs. 38 and 39, whose boundary stress-tensors can be regularized by introducing additional counterterms, here the geometrical simplicity of the WAdS3 space reduces to a factor 1/2. The comparison with the mass computed in [27] is discussed in Appendix C of Ref. 31. Finiteness of (27) follows from cancellations that take place in the near boundary limit. This can be verified by the large r expansion of the \( T_{ij} \) components

\[ T_{tt} \simeq l_{t_{1}}(0) + l_{t_{1}}(1) r^{-1} + l_{t_{1}}(2) r^{-2} + O(r^{-3}), \]

\[ T_{t\phi} \simeq l_{t_{1}}(0) r + l_{t_{1}}(1) r^{-1} + O(r^{-2}), \]

where \( l_{t}^{(n)} \) are constant coefficients that can be found in the Appendix, and the large r expansion of the unit vector components

\[ u^t \simeq u^t_{(1)} + u^t_{(-1)} r^{-1} + O(r^{-2}), \]

\[ u^\phi \simeq u^\phi_{(-1)} r^{-1} + O(r^{-2}). \]

Coefficient \( u^t_{(-1)} \) results proportional to (27).

As mentioned in Ref. 23, in a similar context, mass formula (27) is cumbersome enough for not to doubt about its calculation by means of (24) which actually makes sense. Nevertheless, to convince ourselves about it, let us revise the same type of calculation for TMG and see that it also works when the gravitational Chern-Simons term is included.

V. CONSERVED CHARGES

A. Quasilocal energy

Once the stress-tensor has been improved by adding to it the boundary contributions \( S_B \) that render the Lagrangian finite, one can define the conserved charges as follows [28]

\[ Q[\xi] = \int ds \ u^i T_{ij}^* \xi^j, \]  

(26)

where \( ds \) is the line element of the constant-\( t \) surfaces at the boundary, \( u \) is a unit vector orthogonal to the constant-\( t \) surfaces, and \( \xi \) is the Killing vector that generates the isometry in \( \partial C \) to which the charge is associated. In the case of the mass, the components of this vector are \( \xi^i = N_i u^i \) where the lapse function \( N_s \) in (11). This defines the energy density; see 28, 40 for discussions. From (11) we see that the line element \( ds \) at the boundary we are interested in is simply \( ds = \rho d\varphi \).

However, before going further, let us express concern about the finiteness of (26). This is because the fact that counterterm (23) achieves to make the action finite in the way we discussed it, does not necessarily imply that the stress-tensor is finite as well. In fact, it can be explicitly verified that the inclusion of counterterm (23) with (25) in the case of WAdS3 black holes does not suffice to make all the components of \( T_{ij} \) finite. Nevertheless, it turns out that, despite the divergences in the improved stress-tensor, the charge (26) defined with \( \xi = N \tau^t \) is finite. It gives

\[ M = \frac{\nu^2(\nu^2 + 3)}{2(20\nu^2 - 3)G} \left( r_+ + r_- - \frac{1}{\nu}(\nu^2 + 3)\alpha r_+ \right). \]  

(27)

This agrees with the result obtained in [27, 30, 31] up to a factor 1/2. The comparison with the mass computed in [27] is discussed in Appendix C of Ref. 31. Finiteness of (27) follows from cancellations that take place in the near boundary limit. This can be verified by the large r expansion of the \( T_{ij} \) components

\[ T_{tt} \simeq l_{t_{1}}^{(0)} + l_{t_{1}}^{(1)} r^{-1} + l_{t_{1}}^{(2)} r^{-2} + O(r^{-3}), \]

\[ T_{t\phi} \simeq l_{t_{1}}^{(1)} r + l_{t_{1}}^{(2)} r^{-1} + O(r^{-2}), \]

where \( l_{t_{1}}^{(n)} \) are constant coefficients that can be found in the Appendix, and the large r expansion of the unit vector components

\[ u^t \simeq u^t_{(1)} + u^t_{(-1)} r^{-1} + O(r^{-2}), \]

\[ u^\phi \simeq u^\phi_{(-1)} r^{-1} + O(r^{-2}). \]

Coefficient \( u^t_{(-1)} \) results proportional to (27).

As mentioned in Ref. 23, in a similar context, mass formula (27) is cumbersome enough for not to doubt about its calculation by means of (24) which actually makes sense. Nevertheless, to convince ourselves about it, let us revise the same type of calculation for TMG and see that it also works when the gravitational Chern-Simons term is included.

B. Gravitational Chern-Simons term

Certainly, WAdS3 spaces were first obtained as exact solutions to the equations of motion of TMG [25, 26], and see that it also works when the gravitational Chern-Simons term is included.
and the parameters \( \nu, l \) satisfy the relation \( \nu = \mu l / 3 \). For WAdS\(3 \) black holes of TMG, it had already been observed in [29] that the computation of the mass using the Brown-York tensor in the boundary yielded the result

\[
M = \frac{\nu^2 + 3}{48G} \left( r_+ + r_ - - \frac{1}{\nu} \sqrt{(\nu^2 + 3)(r_+ r_-)} \right),
\]

which, again, is in notable agreement with other calculations using different methods, cf. [1]. In the case of TMG, the large \( r \) limit of \( Q[\xi] \) is regularized by introducing a boundary cosmological term with coefficient

\[
a_0 = -\frac{\sqrt{\nu^2 + 3}}{2l},
\]

which also tends to the AdS\(3 \) value, \(-1/l\), in the limit \( \nu = 1 \). Therefore, the computation of the WAdS\(3 \) black hole mass in terms of the boundary stress-tensor is seen to work in different scenarios.

C. Angular momentum

Now, let us go back to NMG. In contrast to the computation of the mass \( M = Q[N,u] \), charge \( Q[\partial_\varphi] \), which is associated to the WAdS\(3 \) black hole angular momentum, does not yield a finite result in the limit \( r \to \infty \). In fact, boundary terms [24] do not suffice to regularize the divergences appearing in the charge \( Q[\partial_\varphi] = \int ds u^r T^r_\varphi \). This is simply expressed by the fact that \( u_\varphi = 0 \). Nevertheless, the finite part of the large \( r \) expansion of \( Q[\partial_\varphi] \) happens to capture the physically relevant information. This can be seen by looking at the stress-tensor expansion

\[
T_{\varphi \varphi} \simeq t_{\varphi \varphi}^{(1)} r + t_{\varphi \varphi}^{(0)} + O(r^{-1}),
\]

which results in an expansion of the form

\[
Q[\partial_\varphi] \simeq J(2)r^2 + J(1)r + J(0) + O(r^{-1}),
\]

where the coefficient \( J(2) \) depends only on \( \nu \), while coefficient \( J(1) \) depends both on \( \nu \) and \( r_\pm \); namely

\[
J(2) = \frac{9}{8} \frac{\nu(\nu^2 - 1)^2}{20\nu^2 - 3} l^2,
J(1) = \frac{3}{8} \frac{\nu(\nu^2 - 1)}{20\nu^2 - 3} l \left( \frac{\nu^2 + 3}{l} r_+ r_- - 4\nu \sqrt{(\nu^2 + 3)(r_+ r_-)} \right).
\]

From this expansion it is not hard to verify that, in contrast to the case of the mass, for \( \nu^2 \neq 1 \) the introduction of only local counterterms [24] does not produce contributions to cancel the divergences in \( Q[\partial_\varphi] \). However, remarkably enough, the finite part \( J(0) \) gives the correct result for the black hole angular momentum; that is,

\[
J(0) = \frac{\nu(\nu^2 + 3)}{4(20\nu^2 - 3)G} \left[ (5\nu^2 + 3)r_+ r_- - 2\nu \sqrt{(\nu^2 + 3)(r_+ r_-)(r_+ r_-)} \right] .
\]

To see that (30) actually reproduces the correct result one may resort to the computation done in Ref. [24] where the Abbott-Deser-Tekin [42, 43] method to compute conserved charges was used to obtain the WAdS\(3 \) black hole angular momentum. The result obtained in [24] reads

\[
J = \frac{\xi^2 \eta^2}{4Gm^2-1} \left( (1 - \eta^2)\omega^2 - \frac{\rho_0^2}{(1 - \eta^2)} \right),
\]

where \( \xi = 2\nu, \eta = -\sqrt{\nu^2 + 3}/(2\nu), \omega = (r_+ + r_- + 2\eta(r_+ r_-))/2 - 2\eta^2 \), and \( \rho_0^2 = (r_+ - r_-)^2 / 4 \). Then, after translating (31) to our notation, one verifies that (30) is proportional to (31), namely \( J = J(0)\xi^2(1 - \eta^2)/4 \), and the proportionality factor is precisely the (square of the) one that relates the angular coordinates \( \phi \) used in Ref. [24] and our angular coordinate \( \varphi \); more precisely, we have \( \phi = \varphi \sqrt{(\xi^2(1 - \eta^2))/2} \). This proportionality factor \( \xi^2(1 - \eta^2)/4 \) is also explained in Appendix C of Ref. [30]; see equation (C.15) therein. In conclusion, the finite part of charge \( Q[\partial_\varphi] \) captures the physically relevant contribution and gives the correct value of the black hole angular momentum (30). The question remains as to how to understand the failure in regularizing \( Q[\partial_\varphi] \) as a consequence of the abstruse asymptotic structure of WAdS\(3 \) spaces.

VI. DISCUSSION

In this paper we have studied holographic renormalization for three-dimensional massive gravity about WAdS spacetime. The motivation we had for studying this was to investigate to what extent the standard holographic renormalization techniques can be applied mutatis mutandis to spaces that asymptote WAdS\(3 \).

The results of our analysis show that the attempt of directly applying the holographic renormalization recipe to WAdS\(3 \) spaces partially fails and partially succeeds: While, on one hand, such procedure leads to an exact computation of conserved charges of asymptotically WAdS\(3 \) black holes, it does not suffice to define a fully regularized stress-tensor at the boundary of the space. Still, it provides a finite definition of the quasilocal energy density, which gives the right value for the black hole mass. Also, the precise value of the black hole angular momentum is given by the finite part of the large radius expansion of the adequate contraction of the stress-tensor.

At this point, a natural question arises as to why the standard holographic renormalization technique does not suffice to define a finite boundary tensor. To this regard, we would like to discuss an interesting possibility: There is strong evidence that gravity in WAdS\(3 \) is dual to a two-dimensional theory that violates Lorentz invariance, being invariant only under \( SL(2, \mathbb{R}) \times U(1) \) group. Then, it is natural to ask whether supplementing \( T_{ij} \) with counterterms that do not preserve Lorentz invariance could
ultimately result in a finite boundary tensor. Precisely because of the lack of Lorentz invariance, such a tensor would likely be non-symmetric and, in turn, it would not take the form of a Belinfante tensor associated to improved boundary counterterms as in \cite{23}. Still, the question remains as to whether improving $T^{ij}_b$ by adding other kind of Lorentz violating contributions would result in a regularized boundary quantity. Nevertheless, an exhaustive inspection of all the contributions one has at hand, which we collect in the Appendix for completeness, shows that there is no a clear way of improving the boundary tensor without spoiling the right values of conserved charges.

This work has been supported by UBA, CONICET, and ANPCyT. The authors thank Stéphane Detournay, Rodrigo Olea, and Julio Oliva for interesting comments, and they specially thank Alan Garbarz and Mauricio Leston for collaboration and discussions. The authors also thank the referees of JHEP for a very interesting suggestion. G.G. is grateful to the members of Pontificia Universidad Católica de Valparaíso for the hospitality during his stay; specially to Olivera Misković.

VII. APPENDIX

Let us collect the explicit expressions corresponding to the large $r$ expansion of the relevant quantities at the boundary: The components of the stress tensor, given the expansion $T^{ij}_b = t^{(1)}_{t^i} r + t^{(0)}_{t^i} + t^{(-1)}_{t^i} r^{-1} + t^{(-2)}_{t^i} r^{-2} +...$, are given by

\begin{align}
    t^{(0)}_{tt} &= \frac{\nu^2 \sqrt{\nu^2 + 3}}{(20 \nu^2 - 3) \pi l G}, \\
    t^{(-2)}_{tt} &= \frac{\nu^2 \sqrt{\nu^2 + 3} (r_+ - r_-)^2}{4 (20 \nu^2 - 3) \pi l G}, \\
    t^{(1)}_{t^i} &= \frac{3 \nu (\nu^2 - 1) \sqrt{\nu^2 + 3}}{8 (20 \nu^2 - 3) \pi l G}, \\
    t^{(0)}_{t^i} &= \frac{\nu \sqrt{\nu^2 + 3}}{16 (20 \nu^2 - 3) \pi l G} ((5 \nu^2 + 3)(r_+ + r_-) + 8 \nu \sqrt{\nu^2 + 3} r_+ r_-), \\
    t^{(-1)}_{t^i} &= \frac{3 \nu (\nu^2 - 1) \sqrt{\nu^2 + 3} \nu (r_+ + r_-)}{8 (20 \nu^2 - 3) \pi l G} - \frac{\nu \sqrt{\nu^2 + 3}}{32 (20 \nu^2 - 3) \pi l G} ((13 \nu^2 + 3)(r_+^2 + r_-^2) - 2(5 \nu^2 + 3) \nu r_+ r_- (r_+ + r_-) - 2r_+ (5 \nu^2 - 21) r_+ r_-). \tag{37}
\end{align}

On the other hand, the non-vanishing components of boundary metric, denoted as $\gamma_{ij} \simeq \gamma^{(2)}_{ij} r^2 + \gamma^{(1)}_{ij} r + \gamma^{(0)}_{ij} +...$, are the following

\begin{align}
    \gamma^{(0)}_{tt} &= 1, \\
    \gamma^{(1)}_{t^i} &= \nu, \\
    \gamma^{(0)}_{t^i} &= -\frac{1}{2} \sqrt{(\nu^2 + 3) r_+ r_-}, \\
    \gamma^{(2)}_{t^i} &= \frac{3}{4} (\nu^2 - 1), \\
    \gamma^{(1)}_{t^i} &= \frac{1}{4} (\nu^2 + 3)(r_+ + r_-) - \nu \sqrt{(\nu^2 + 3) r_+ r_-}. \tag{42}
\end{align}

The components of $\tilde{f}_{ij}$, following the same notation, namely $\tilde{f}_{ij} = \tilde{f}^{(2)}_{ij} r^2 + \tilde{f}^{(1)}_{ij} r + \tilde{f}^{(0)}_{ij} +...$, are given by

\begin{align}
    \tilde{f}^{(0)}_{tt} &= -\frac{4 \nu^2 - 3}{m^2 l^2}, \\
    \tilde{f}^{(1)}_{t^i} &= -\frac{4 \nu (\nu^2 - 3)}{m^2 l^2}, \\
    \tilde{f}^{(0)}_{t^i} &= \frac{(4 \nu^2 - 3) \sqrt{(\nu^2 + 3) r_+ r_-}}{2 m^2 l^2}, \\
    \tilde{f}^{(2)}_{t^i} &= -\frac{9 (\nu^2 - 1)(2 \nu^2 - 1)}{4 m^2 l^2}, \\
    \tilde{f}^{(1)}_{t^i} &= \frac{(2 \nu^2 - 3)(\nu^2 + 3)(r_+ + r_-)}{4 m^2 l^2} \nu (4 \nu^2 - 3) \sqrt{(\nu^2 + 3) r_+ r_-} + \frac{\nu (4 \nu^2 - 3) \nu r_+ r_-}{m^2 l^2}, \tag{47}
    \tilde{f}^{(0)}_{t^i} &= \frac{3 (\nu^2 - 1)(\nu^2 + 3) r_+ r_-}{2 m^2 l^2}. \tag{48}
\end{align}

Other relevant quantity for the boundary terms is tensor $\nabla_r \tilde{f}_{ij}$, whose components in the large $r$ expansion, $\nabla_r \tilde{f}^{(n)}_{ij}$, are the following

\begin{align}
    \nabla_r \tilde{f}^{(0)}_{tt} &= 0, \\
    \nabla_r \tilde{f}^{(1)}_{t^i} &= -\frac{6 \nu (2 \nu^2 - 3) \sqrt{\nu^2 + 3} r_+}{m^2 l^2}, \tag{49}
    \nabla_r \tilde{f}^{(0)}_{t^i} &= -\frac{\nu \sqrt{\nu^2 + 3}(2 \nu^2 - 3)(r_+ + r_-)}{2 m^2 l^2}, \tag{50}
    \nabla_r \tilde{f}^{(2)}_{t^i} &= \frac{2 \nu (\nu^2 - 1)(2 \nu^2 - 9) \sqrt{\nu^2 + 3} + 3}{4 m^2 l^2}, \tag{51}
    \nabla_r \tilde{f}^{(1)}_{t^i} &= \frac{(2 \nu^2 - 3) \nu \sqrt{\nu^2 + 3}((\nu^2 - 3)(r_+ + r_-) + 2 \nu \sqrt{(\nu^2 + 3) r_+ r_-})}{2 m^2 l^2}, \tag{52}
    \nabla_r \tilde{f}^{(0)}_{t^i} &= \frac{(2 \nu^2 - 3)(\nu^2 + 3)(\nu r_+ r_- + \nu \sqrt{3(r_+ r_-)} - 4 \nu \sqrt{r_+ r_- - (r_+ + r_-)} + \sqrt{\nu^2 + 3} r_+ r_-)}{2 m^2 l^2}. \tag{53}
\end{align}
Contributions to charges $M = 2\pi \rho u^t T^t_{\varphi} \xi^i$ and $J = 2\pi \rho u^t T^t_{\varphi}$ coming from the large $r$ expansions $M \approx M(1)r + M(0) + \ldots$ and $J \approx J(1)r^2 + J(0)r + \ldots$ are composed as follows: For the mass, we have

\[
\frac{M(1)}{2\pi} = \rho(1) u^t_{(0)} t^t_{(0)} + \rho(1) u^t_{(0)} t^t_{(0)} s^t_{-1} + \rho(1) u^t_{(0)} t^t_{(0)} \xi^t_{-1} = 0,
\]

\[
\frac{M(0)}{2\pi} = \rho(0) u^t_{(0)} t^t_{(0)} + \rho(0) u^t_{(0)} t^t_{(0)} s^t_{-2} + \rho(0) u^t_{(0)} t^t_{(0)} \xi^t_{-2} = 0,
\]

where $\rho^{(n)}$ refer to the components of the large expansion of metric function $[12]$ in powers of $r$; analogously for the large $r$ expansion of $u^t = u^t_{(0)} + u^t_{(1)} r^{-1} + u^t_{(2)} r^{-2}$, $u^\varphi \approx u^\varphi_{(-1)} r^{-1} + u^\varphi_{(-2)} r^{-2}$, and the Killing vectors $\xi^t = \xi^t_{(0)} = 1$, $\xi^\varphi \approx \xi^\varphi_{(-1)} r^{-1} + \xi^\varphi_{(-2)} r^{-2}$. For the angular momentum, the analogous expression is

\[
\frac{J(2)}{2\pi} = \rho(1) u^t_{(0)} t^t_{\varphi},
\]

\[
\frac{J(1)}{2\pi} = \rho(0) u^t_{(0)} t^t_{\varphi} + \rho(1) u^t_{(1)} t^t_{\varphi} + \rho(0) u^t_{(0)} t^t_{\varphi} + \rho(1) u^t_{(1)} t^t_{\varphi},
\]

\[
\frac{J(0)}{2\pi} = \rho(0) u^t_{(0)} t^t_{\varphi} + \rho(0) u^t_{(1)} t^t_{\varphi} + \rho(0) u^t_{(0)} t^t_{\varphi} + \rho(1) u^t_{(1)} t^t_{\varphi} + \rho(0) u^t_{(0)} t^t_{\varphi} + \rho(0) u^t_{(1)} t^t_{\varphi} + \rho(0) u^t_{(0)} t^t_{\varphi} + \rho(0) u^t_{(0)} t^t_{\varphi}.
\]

Then, one finds that the mass of the black hole is given by $M(0)$ while its angular momentum is given by $J(0)$.
