Background: Ileus is common after gastrointestinal surgery and has been identified as a research priority. Several issues have limited previous research, including a widely accepted definition and agreed outcome measure. This review is the first stage in the development of a core outcome set for the return of bowel function after gastrointestinal surgery. It aims to characterize the extent of variation in current outcome reporting.

Methods: A systematic search of MEDLINE, Embase, CINAHL (Cumulative Index to Nursing and Allied Health Literature) and the Cochrane Library was performed for 1990–2017. RCTs of adults undergoing gastrointestinal surgery, including at least one reported measure relating to return of bowel function, were eligible. Trial registries were searched across the same period for ongoing and completed (but not published) RCTs. Definitions of ileus and outcome measures describing the return of bowel function were extracted.

Results: Of 5670 manuscripts screened, 215 (reporting 217 RCTs) were eligible. Most RCTs involved patients undergoing colorectal surgery (161 of 217, 74.2 per cent). A total of 784 outcomes were identified across all published RCTs, comprising 73 measures (clinical: 63, 86 per cent; radiological: 6, 8 per cent; physiological: 4, 5 per cent). The most commonly reported outcome measure was ‘time to first passage of flatus’ (140 of 217, 64.5 per cent). The outcomes ‘ileus’ and ‘prolonged ileus’ were defined infrequently and variably.

Conclusion: Outcome reporting for the return of bowel function after gastrointestinal surgery is variable and not fit for purpose. An agreed core outcome set will improve the consistency, reliability and clinical value of future studies.

Introduction
Ileus, defined as a delayed return of bowel function after surgery, occurs in 10–20 per cent of patients undergoing elective gastrointestinal surgery, and may lead to painful abdominal distension, vomiting, constipation and distress. As part of its research prioritization process, the Association of Coloproctology of Great Britain and Ireland identified ileus as a research priority, and called for further research to identify clinically effective, patient-focused management strategies.

Over the past 20 years, numerous interventions to optimize the return of bowel function have been tested in RCTs. Many were limited by methodological challenges related to the assessment of complex interventions and heterogeneity in the choice of outcome measures. Poor standardization and variation in the use of outcome measures is problematic for translation into clinical practice. Although several groups have attempted to address this problem through consensus statements, the impact of these efforts remains unclear.
The COMET (Core Outcome Measures in Effectiveness Trials) Initiative aims to develop agreed ‘core outcome sets’, which represent the minimum information that should be reported in all trials of a specific condition. No such outcomes set for the return of bowel function after gastrointestinal surgery has been developed. Consistent reporting would increase the value of RCTs, improve the quality of meta-analyses and enhance decision-making when integrating new treatments into clinical practice.

This review represents the first stage in the development process. It aimed to identify all reported outcome measures for the return of bowel function used in RCTs of gastrointestinal surgery, as well as characterizing the extent of variation in order to develop an interim strategy for maximizing the value of future studies.

Methods

Study design

This study was developed with the assistance of patient representatives at a national stakeholder meeting in London, UK in April 2017. A systematic review was performed according to a predefined protocol. It was registered prospectively on the PROSPERO database of systematic reviews (CRD42017082351) and reported in line with the PRISMA guidelines.

Search

A search strategy was developed to identify outcome measures used to assess the return of bowel function after gastrointestinal surgery (Table S1, supporting information). Two independent investigators performed searches of MEDLINE (via OvidSP), Embase (via OvidSP), CINAHL (Cumulative Index to Nursing and Allied Health Literature) (via EBSCOhost) and the Cochrane Library on 15 June 2017. Titles and abstracts were screened for eligibility via Covidence Systematic Review Software (Veritas Health Innovation, Melbourne, Australia; www.covidence.org), followed by inspection of full-text manuscripts as appropriate. Discrepancies between investigators were discussed with the review team until consensus was achieved. All ‘primary registries’ included in the WHO Registry Network (including ClinicalTrials.gov) were queried for ongoing and completed (but unpublished) RCTs (Table S2, supporting information). A simplified search strategy (ileus AND surgery) was applied to these databases. Unique trial identifiers and details of corresponding authors were
Eligibility criteria

All RCTs including adult patients (18 years old or above) undergoing gastrointestinal surgery were eligible for inclusion. Eligible studies had to include at least one outcome measure (primary or secondary) describing the return of bowel function or the incidence of ileus. RCTs published in a peer-reviewed journal (in print or online) or registered on a WHO-approved trials registry were included. Non-randomized study designs, reports published in a non-English language and grey literature were excluded.

Outcomes

The primary outcome was the number of outcome measures relating to the return of bowel function. Secondary outcomes were the type of outcome (primary or secondary) and mode of measurement (clinical, radiological or physiological). If outcomes of ‘ileus’ were reported, the definition assigned to ileus (or absence of) was documented.

Definitions

RCTs were defined as prospective studies with participants randomized to one of a minimum of two intervention groups. Gastrointestinal surgery was defined as any surgical procedure performed on the oesophagus, stomach, small bowel, colon, rectum or anus. The primary outcome of each RCT was identified according to information provided in the manuscript or trial registry entry, if available. Where ambiguity persisted, the primary outcome was identified according to the study’s reported sample-size calculation. Only outcomes describing the return of bowel function were considered; adverse events (such as nausea attributed directly to opioid consumption) and other generic measures of recovery (such as duration of hospital stay) were not considered. Outcome measures were classified as ‘clinical’ measures (those measured by clinicians or reported by patients), ‘physiological’ (those measuring physiological processes) and ‘radiological’ (those measured using either cross-sectional or non-cross-sectional imaging). They were further classified according to core areas described by the OMERACT (Outcome Measures in Rheumatology) filter 2.0, including: Life Impact, Pathological Manifestations and Resource Use\(^{11}\). The core area of Death was not considered relevant in the present context. Individual outcome measures could be classified into one or multiple core areas.

Data extraction

A single investigator extracted data from eligible manuscripts. Data fields of interest included manuscript demographics (journal and year), procedure type and study characteristics (setting, population, recruitment and blinding). If data extraction was unclear, corresponding authors were contacted for clarification. Study outcome
## Table 2: Reported outcomes in published RCTs

| Reported outcome measure | No. of reports | Mode of outcome | Primary outcome | Secondary outcome | Unclear outcome |
|-------------------------|----------------|----------------|----------------|------------------|-----------------|
|                         | Total          | Colorectal*    | UGI            |                  |                 |
| Time to first passage of flatus | 140           | 120           | 20            | Clinical         |                 |
| Time to first passage of stool | 69            | 62            | 7             | Clinical         |                 |
| Time to first bowel movement | 65            | 61            | 4             | Clinical         |                 |
| Incidence of postoperative ileus | 58            | 52            | 6             | Clinical         |                 |
| Need for nasogastric tube/replacement | 45            | 37            | 8             | Clinical         |                 |
| Incidence and/or duration of vomiting | 38            | 35            | 3             | Clinical         |                 |
| Time to first fluid intake | 28            | 25            | 3             | Clinical         |                 |

| Gastric emptying: acetate breath test | 1 | 1 | 0 | Physiological | 0 (0) | 1 (100) | 0 (0) |

Values in parentheses are percentages. *Number of reports in colorectal studies (including studies of mixed colorectal and upper gastrointestinal tract (UGI)). GI-2, composite outcome measure – time taken to pass first stool and tolerate oral intake; GI-3, composite outcome measure – time taken to pass first stool or flatus and tolerate oral intake; QoL, quality of life; HIDA, hepatobiliary iminodiacetic acid.

measures were extracted verbatim and grouped to produce frequencies. At this stage, small variations in reporting (such as ‘time to pass stool’ and ‘time taken to pass stool’) were rationalized.

Statistical analysis

Descriptive data are expressed using proportions and median values. A subgroup analysis of outcome measures for lower (colorectal) versus upper gastrointestinal surgery was planned prospectively. All data were entered into Microsoft Excel® (Microsoft, Redmond, Washington, USA) for analysis.

Bias assessment

As this review reported a summary description of outcome measures used in RCTs, rather than a measure of clinical data, assessments of bias for each RCT were not performed12,13.

Results

Study characteristics

A total of 5670 manuscripts were screened for eligibility, and 215 (reporting 217 RCTs) were included in the review (Fig. 1; Table S3, supporting information). Most
### Table 3: Planned outcome measures in trial register entries

| Reported outcome measure                                      | Mode of outcome | No. of reports (n = 96) |
|----------------------------------------------------------------|----------------|-------------------------|
| Time to first passage of flatus                              | Clinical        | 44 (46)                 |
| Time to first passage of stool                               | Clinical        | 30 (31)                 |
| Incidence of postoperative ileus                             | Clinical        | 28 (29)                 |
| Time to first bowel movement                                 | Clinical        | 18 (19)                 |
| Time to tolerate solid intake                                | Clinical        | 16 (17)                 |

| Gastrointestinal transit: number of evacuated SITZMARKS® markers (radiograph) | Radiological   | 1 (1)                   |
| Incidence and/or duration of oral intolerance                | Clinical        | 1 (1)                   |
| Abdominal circumference ratio                                 | Clinical        | 1 (1)                   |
| Time to first stoma output                                   | Clinical        | 1 (1)                   |
| Incidence of morbidity due to postoperative ileus            | Clinical        | 1 (1)                   |
| Incidence of gastric upset                                   | Clinical        | 1 (1)                   |
| Gastrointestinal Quality of Life Index (GIQLI) score          | Clinical        | 1 (1)                   |
| Gastrointestinal motility: dynamic MRI                       | Radiological    | 1 (1)                   |

Values in parentheses are percentages. SITZMARKS® (Konsyl Pharmaceuticals, Easton, Maryland, USA). GI-2, composite outcome measure – time taken to pass first stool and tolerate oral intake; GI-3, composite outcome measure – time taken to pass first stool or flatus and tolerate oral intake.

RCTs involved patients undergoing colorectal surgery (161, 74.2 per cent), and the majority tested either a drug (100, 46.1 per cent) or a procedural (64, 29.5 per cent) intervention. Institutions in Asia (82 of 217, 37.8 per cent), Europe (70 of 217, 32.3 per cent) and North America (44 of 217, 20.3 per cent) were the most frequent study locations. The majority of RCTs were single-centre studies (173, 79.7 per cent) reporting on small populations (fewer than 100 participants) (139, 64.1 per cent). The median number of outcomes relating to the return of bowel function was 3 (i.q.r. 2–5), and 82 RCTs (37.8 per cent) included one of these as a primary study outcome. Full study characteristics are shown in Table 1.

### Published outcome measures

Across all RCTs, a total of 784 outcomes relating to the return of bowel function were reported. These comprised 73 discrete outcome measures (Table 2). Approximately one-third (25 of 73, 34 per cent) of identified outcome measures were reported only once without replication. Overall, the most frequently reported measures were ‘time to first passage of flatus’ (140 of 217, 64.5 per cent), ‘time to first passage of stool’ (69 of 217, 31.8 per cent) and ‘time to first bowel movement’ (65 of 217, 30.0 per cent). This differed slightly for the subset of RCTs involving upper gastrointestinal surgery, where the most common outcome measures were ‘time to first passage of flatus’ (20 of 29, 69 per cent), ‘need for nasogastric tube insertion/reinsertion’ (8 of 29, 28 per cent) and ‘time to first passage of stool’ (7 of 29, 24 per cent).

### Planned outcome measures

Some 96 eligible registry entries were identified (Fig. 1). Assessment of these entries identified 224 planned
outcomes, comprising 36 discrete outcome measures relating to the return of bowel function (Table 3). The median number per trial was 2 (i.q.r. 1–3). The most commonly planned outcome measures were similar to those in published manuscripts, including ‘time to first passage of flatus’ (44 of 96, 46 per cent), ‘time to first passage of stool’ (30 of 96, 31 per cent) and ‘incidence of postoperative ileus’ (28 of 96, 29 per cent). Two unique outcome measures were identified, including ‘Gastrointestinal Quality of Life Index (GIQLI) score’ (1 of 96, 1 per cent) and ‘Gastrointestinal motility: dynamic MRI’ (1 of 96, 1 per cent). These were not replicated elsewhere.

Classification of outcome measures

Across published and planned RCTs, clinical outcome measures (including clinical scales, instruments and consultations) were largely favoured: 63 of 73 (86 per cent) and 33 of 36 (92 per cent) respectively (Fig. 2). Radiological modalities comprised six of 73 (8 per cent) published measures and three of 36 (8 per cent) planned measures in trial registries. These included radiographic, nuclear and MRI assessments of gastrointestinal transit. Physiological measures were infrequent (4 of 73 (5 per cent) and 0 of 36 (0 per cent) respectively), and included measures of gastric emptying such as acetate breath-testing, paracetamol (acetaminophen) absorption and gastric manometry. The vast majority of outcome measures were relevant to Life Impact and Pathological Manifestation core areas, with few concerned with Resource Use.

Definitions of ileus

The outcome measures postoperative ileus and prolonged postoperative ileus were defined in 17 of 58 reports (29 per cent) and their duration was described in five of 13 reports (38 per cent). All reported definitions demonstrated considerable variability (Table 4). Most incorporated elements of both upper and lower gastrointestinal function (7 of 17 (41 per cent) and 4 of 5 (80 per cent) respectively), followed by elements of lower gastrointestinal function alone (6 of 17 (35 per cent) and 1 of 5 (20 per cent)). The majority of definitions defined postoperative ileus or prolonged postoperative ileus according to incidence (12 of 17 (71 per cent) and 4 of 5 (80 per cent)), whereas the remainder defined them according to the time taken to resolve (5 of 17 (29 per cent) and 1 of 5 (20 per cent)).
Table 4 Definitions of ileus as reported in published literature

| Definition: incidence/duration of ‘postoperative ileus’ (n = 17 of 58, 29 per cent) |
|---|
| ‘delay of the first postoperative flatus lasting for >72 hours (3-0 days) after surgery … or some other status requiring intervention for treatment for ileus’ |
| ‘Patients meeting 2 or more of the following 5 criteria on or after day 4 postoperatively – nausea OR vomiting over the preceding 12 hours; inability to tolerate a solid or semi-solid oral diet over the preceding 2 meal times; abdominal distension; absence of flatus AND stool over the preceding 24 hours; and radiologic evidence of ileus on abdominal plain film or CT over the preceding 24 hours’ |
| ‘defined as lack of passage of flatus or stool and intolerance to oral intake for at least 24 h … on day 5 after operation’ |
| ‘intolerance to oral food in the absence of clinical and radiological data of mechanical obstruction for more than 72 hours, or the need for a nasogastric tube’ |
| ‘ileus persisted until patient had normal bowel sounds or he/she was passing flatus’ |
| ‘defined as failure of bowel sounds to return within 12 h postoperatively’ |
| ‘the number of days before signs of restoration of the bowel function appeared (bowel movement, flatus, and stool) after which oral intake was restarted’ |
| ‘resolution defined as passage of flatus or stool in the absence of nausea, vomiting, or abdominal distention’ |
| ‘need for nasogastric tube reinsertion or discontinuation of oral intake’ |
| ‘ADynamic or paralytic ileus that persisted for >3 days following surgery’ |
| ‘the condition in which the time required for the resumption of flatus passage after surgery exceeded 48 hours’ |
| ‘The resolution of postoperative ileus was defined as having a bowel movement in the absence of abdominal distention and vomiting’ |
| ‘the interval between the end of surgery and the first passage of gas or stool through the anus’ |
| ‘defined as postoperative nausea/vomiting, accompanied by abdominal distention, absence of bowel function, and x-ray findings consistent with ileus’ |
| ‘non-passage of gas or solid per rectum for 5 days, cessation of such passage, vomiting (on day 1), nasogastric intubation, continued intravenous fluids’ |
| ‘abdominal distension, no flatus or bowel movement, or nausea/vomiting that prevents oral intake or requires therapeutic use of nasogastric tube’ |
| ‘the inability to tolerate and resume oral solid diet intake beyond 6 days after surgery’ |

| Definition: incidence/duration of ‘prolonged postoperative ileus’ (n = 5 of 13, 38 per cent) |
|---|
| ‘The presence of two or more of the following signs/symptoms over the 4th postoperative day: abdominal distension, persistent and nonspecific abdominal pain, vomits and/or nausea, the absence of passage of flatus or stools, oral intolerance, and radiological findings on plain radiology’ |
| ‘Defined as being resolved when all 4 of the following criteria were met – absence of nausea AND vomiting for 12 hours with nasogastric tube spigotted or removed; ability to tolerate a solid or semi-solid diet at the preceding mealtime; absence of abdominal distension; and passage of flatus OR stool over the preceding 24 hours’ |
| ‘no passage of flatus or stool by the end of the fifth post-operative day’ |
| ‘the inability to tolerate 5 days after surgery in the absence of active bowel sounds with the need for nasogastric decompression’ |
| ‘Two or more of the following criteria: (i) nausea/vomiting, (ii) inability to tolerate an oral diet for >24 h, (iii) absence of flatus for >24 h, (iv) distension and (v) radiological confirmation occurring on or after day 4 postoperatively without prior resolution of POI’ |

Discussion

This review identified multiple outcome measures describing the return of bowel function after gastrointestinal surgery. There was consistency in reporting of a small number of terms, such as ‘time to first passage of flatus’ and ‘time to first passage of stool’, but one-third of all measures were used only once without replication. The return of bowel function was often reported using multiple outcomes, which may have led to inconsistent results and unclear conclusions. When ileus was reported as an outcome, a corresponding definition was frequently not given; when this was provided, definitions varied considerably.

Previous research on ileus has been limited by several methodological challenges, including the lack of an agreed definition, such as the wide variation in definitions for prolonged ileus in studies of colorectal surgery. Several attempts have been made to overcome these difficulties through consensus agreements. A systematic review and global survey proposed a series of definitions for postoperative ileus, prolonged postoperative ileus and recurrent ileus to delineate broad patterns of bowel dysfunction. An international Delphi process found consensus on the importance of abdominal pain, distension and bowel sounds for identifying ileus in clinical practice. The role of bowel sounds was later discredited as a reliable measure. Other efforts have included scoring tools to measure the clinical impact of delayed return of bowel function. Some groups attempted to validate composite outcome measures such as the composite measure GI-2 (defined as time to tolerance of oral diet and passage of stool) with good results (area under the curve 0.9). Currently, this offers the most representative assessment of return of gastrointestinal function after surgery, whereas the validity of other commonly used outcome measures remains unclear. Clinicians are increasingly recognizing the return of bowel function as a continuous spectrum, rather than a dichotomous outcome, ranging from transient nausea and vomiting to severe bowel dysmotility.
Measuring the return of bowel function is important for clinicians and those responsible for planning and commissioning surgical services. For surgeons, it is important as a means of reducing postoperative complications. Previous research\(^{19}\) has suggested that early identification of delayed bowel function (followed by targeted interventions such as nasogastric decompression) may decrease the incidence of pulmonary complications. In the absence of consistent outcome measures, undertaking reliable meta-analysis will remain difficult or simply impossible. For those involved in the organization of surgical services, it is important to have reliable evaluations of new treatments in order to plan the provision of efficient clinical services. Agreement on a core outcome set may offer an effective solution.

Based on this review, researchers should rationalize the number of outcome measures relating to the return of bowel function until an agreed core outcome set exists. To avoid multiple, conflicting results across different measures, a clear primary outcome should be declared, with a corresponding definition. This should be registered on an approved trial registry to maximize transparency and reduce reporting bias. In the meantime, researchers should consider using the composite outcome measure GI-2 (time to tolerance of oral diet and passage of stool) as a validated, evidence-based measure that reflects the return of both upper and lower gastrointestinal function. Researchers should also consider the routine collection of quality of life data.

Previous studies have focused on broad definitions of ileus in the setting of colorectal surgery; this may not reveal the full extent of the issue. Return of gastrointestinal function is a challenge in many fields of abdominal (and non-abdominal) surgery. As the focus of this review is on clinical manifestations (rather than pathophysiological mechanisms), cautious extrapolation of these results across these other surgical areas might still be reasonable. This review was unable to distinguish between measures of ileus and postoperative nausea and vomiting. While these may well represent different aetiological entities, their clinical manifestations share similarities and a pragmatic (patient-focused) perspective of gastrointestinal function is encouraged. As this review focused on RCTs of gastrointestinal surgery, and excluded studies with an observational design, the benefits of prospective design have to be balanced against the extent of generalizability of the results to an unselected population.

The reporting of postoperative bowel function is limited by unacceptable variation in outcome measures and a paucity of evidence to describe their validity. This undoubtedly contributes to the challenges encountered in identifying and evaluating the return of bowel function after gastrointestinal surgery. An agreed core outcome set is required.
