Abstract

Background

The postnatal period is associated with new needs for mothers. Four categories of needs were highlighted in our previous study: for information, for psychological support, for the sharing of experiences and for practical and material support. The aims of this study were as follows: (1) to validate these 4 needs by comparing recent mothers’ needs with the needs of pregnant women and (2) to compare these needs between primiparous and multiparous women.

Methods

The 4 needs previously identified were investigated by online self-report questionnaires completed by women in their last trimester of pregnancy and by mothers who had a child between 0 and 6 months of age.

Results

The 4 needs were largely present during the postpartum period. The need for information seemed to be more present during pregnancy (92.4%) than during the postpartum period (84.6%, p = 0.03), but women used the Internet significantly more often to search for information after childbirth (54.8%) than during pregnancy (41.2%, p < 0.0001). The needs for psychological support and to share experiences seemed to be closely linked. Even if the global satisfaction with psychological support was fairly high, it weakened after childbirth (p < 0.05). Feelings of loneliness (p < 0.0001) and depression scores (p = 0.01) were also higher during the postpartum period than during pregnancy. Not surprisingly, primiparous women felt less reassured in their roles as mothers and more stressed during the postpartum period than multiparous women (p < 0.0001). Finally, the need for practical support was also more pronounced during the postpartum period than during pregnancy (p = 0.01).

Conclusion

All mothers seem to meet the 4 identified needs during the postpartum period but at different levels of intensity. Trying to meet these needs could offer an opportunity to improve mothers’ quality of life.

Background

The transition to motherhood is one of the greatest changes in a woman’s life [1, 2]. The postnatal period is a stressful time that brings not only physical but also psychological and social changes [3, 4]. After childbirth, the “maternal psyche” invades the entire psychic life of women, determining their thoughts and behaviors and leading them to take care of their babies instead of taking care of themselves [5, 6].
Mothers must therefore address these sudden and intense changes in their roles and responsibilities [7–9].

Thus, the postnatal period is associated with new needs for mothers. A previous study in our department evaluated the needs of mothers in the year after childbirth from a qualitative perspective [10]. Four categories of needs were highlighted: needs for information, for psychological support, for the sharing of experiences and for practical and material support. Primiparous and multiparous women seemed to have similar needs but at different levels of intensity. For example, this previous study showed that primiparous women perceived a greater lack of information from many perspectives (medically, administratively, regarding existing services, feeling unprepared for motherhood, reliability of information, etc.) than did multiparous women [10]. Indeed, the need for information appeared to decrease and become more specific for subsequent children. In attempting to meet this need, mothers are increasingly turning to the Internet to help themselves make decisions and manage their postpartum lives [10–16].

With respect to the needs for psychological support and the sharing of experience, it has already been shown that women often have many fears and anxieties regarding early motherhood and their changing role [10, 17] and perceive a lack of control over their lives, incomplete maternal feelings and unstable relationships with their husbands and others [4, 10]. Women therefore need to be surrounded, reassured and understood by those who will emotionally support them, especially by the fathers of their children but also by other mothers [10, 18–20]. In addition, isolation and feelings of loneliness recur during the postnatal period [10]. Finally, the majority of women expressed the need for help with housework chores, especially in the first few postpartum weeks [10].

This previous study used a qualitative method that was well adapted to explore the mothers’ needs during the postnatal period and to obtain very rich results allowing participants to express themselves freely and spontaneously [21]. Nevertheless, one limitation of qualitative investigations is that, even if they focus on the particularities and allow for the extraction of tendencies from the collected interviews, they do not allow for the measurement of the frequencies of the themes highlighted. Thus, it was not possible to generalize the results. For this reason, it was also important to explore these needs quantitatively on a larger scale. In addition, to our knowledge, there is no study that compares maternal needs during and after pregnancy. Therefore, the primary aim of the present study was to validate the 4 previously identified needs (for information, for psychological support, for the sharing of experiences and for practical and material support [10]) by comparing the mothers’ needs with the needs of pregnant women. The secondary aim of this study was to compare these needs between primiparous and multiparous women.

**Methods**

**Study design**

The 4 needs previously identified (for information, for psychological support, for the sharing of experiences and for practical and material support [10]) were investigated by online self-report questionnaires among women in their last trimester of pregnancy and among mothers who had a child
between 0 and 6 months of age. This study received ethics approval from the “Comité d'Ethique Hospitalo-Facultaire Universitaire de Liège” under the number 2017/14. A complete written description of the research, including intends to publish, was provided to the participant at the beginning of the first questionnaire. This information page had to be approved to continue to the questionnaire. Participation in the study was therefore considered to indicate the consent of the respondent. The email addresses of the participants were necessary to be able to contact them for the second part of the study. Participation in the survey was therefore confidential.

**Participants and sample**

All the pregnant women with at least 32 weeks of amenorrhoea and all the mothers who had a child between 0 and 6 months of age were included in this study. The inclusion criteria were as follows: being pregnant for at least 32 weeks or having a child between 0 and 6 months of age; giving birth in Belgium; understanding French; having any access to the Internet (at home, at work, via a smartphone, etc.); and agreeing to participate in the study. The exclusion criteria were foetal death in utero, very premature childbirth (< 34 weeks of gestation), foetal pathologies and multiple pregnancies.

**Questionnaires and parameters investigated**

A literature review highlighted that none of the published instruments were able to meet the objectives of this research. A questionnaire was therefore designed specifically for this study. Indeed, the objective of the study was to evaluate the mothers’ needs in regard to the result of the previous study conducted by our department, namely, the needs for information, for psychological support, for the sharing of experiences and for practical and material support [10]. There were two types of questionnaires: one questionnaire for pregnant women from 32 weeks of gestation until birth and one questionnaire for mothers who had children between 0 and 6 months of age. These two questionnaires contained similar questions to evaluate the mothers’ needs and specific questions about pregnancy or birth with respect to the different cases.

Questionnaires included mainly structured multiple choice questions and few very short answer questions. In addition, there were 4 validated questionnaires at the end of the survey. Mothers had the possibility of responding to these 4 questionnaires or to pass them. The questionnaire was first constructed through a web platform ([www.sondageonline.com](http://www.sondageonline.com)). Then, it was pretested by 6 women (2 of whom were mothers and 4 of whom were not mothers but who were used to developing questionnaires), which led to very minor changes. Complete information about the study was provided at the beginning of the questionnaire. Participation in the study was therefore considered to indicate the consent of the respondent. The email addresses of the participants were necessary to be able to contact them for the second part of the study. Participation in the survey was therefore confidential.

**Background variables**

The first set of structured questions gathered information about various sociodemographic parameters that could influence the mothers’ experiences: age; socioeconomic status (combined level of education,
professional status and household income (a subjective evaluation of the economic level was made by asking participants if they had the feeling that their financial resources allowed them to meet their household needs and was coded from very difficult to very easy; an objective evaluation was made by asking participants to provide their household's monthly net income)); marital status; number of children; district of residence; ethnicity and Internet-related skills. Women were also asked if they worked in the medical or paramedical field and if they worked with children between 0 and 2 years of age.

Pregnancy and postnatal profiles were also investigated for the following items: history of last pregnancy (e.g., pregnancy monitoring, prenatal care, any health problem during the pregnancy) or childbirth and postnatal period (only for women who had already given birth: i.e., date of birth, gestational age, type of delivery, epidural, any problem during delivery, weight of the baby, history of the maternity stay); and type and experience of feeding. The experience of going back home after delivery was also investigated in women who had already given birth.

The couple relationship was also evaluated. Mothers were asked to describe the relationship with their partner (scale of 0–10: 0 = very negative, 10 = very positive) and to indicate how they would educate their baby (the possible answers were as follows: with the father of the baby, with my partner who is not the father of the baby, alone, with my wife (for a homosexual couple), or “other”, which required further).

**Need for information**

Mothers were first asked if they searched for information about pregnancy, about the maternity stay or, if they had already given birth, about postnatal issues (about the baby or themselves) and what information they searched for. Mothers were next asked whether they used the Internet to search for pregnancy or postnatal issues (about the baby or herself), whether they used other sources for searching information, what was their reasoning for this search strategy, whether they had one or more favorite websites to search, and the frequency with which they searched. They were also asked whether they found the information that they sought and if it was easy or difficult to find it. They were then requested to give a score on a 10-cm scale to assess how they felt about the reliability of the health information found on the Internet and to say if they had already visited a website verifying whether the information was incomplete or incorrect. The questionnaire also inquired how mothers used the information that they found (utility of the information) and whether their daily decision making was influenced by this information. Thus, the decision-making process was investigated. Indeed, the women were asked to rate their confidence in decision making (scale of 0–10) for their own health and for their child's health both before and after using the Internet. In addition, the following question was asked to mothers: ‘Did the information that you found on the Internet influence the way you have thought of managing your child (e.g., diet, illness, sleep, games, pacifier, etc.)?’ (scale of 0–10: 0 = not at all, 10 = absolutely).

Then, the reasons to search information on the Internet were also investigated. Following a review of the literature and previous studies conducted in our department, a list was created with different possible reasons for searching information from the Internet. These reasons were proposed to the respondents in the form of a structured questionnaire, and no space was given for additional explanations.
In addition, the questionnaire inquired whether the hospital in which they gave birth or were to give birth provided an online information tool to them and if they used it and were satisfied with it. The women were finally asked if they believed that health professionals should suggest suitable and reliable Internet websites where mothers could find relevant information about pregnancy or the postpartum period.

**Need for psychological support**

To explore the need for psychological support, mothers were asked, on a scale from 0 to 10, the following questions: if they felt supported by their companion, their family and their friends; if they felt alone, stressed, anxious and tired; and if they felt reassured in their (future) role of mothers. They were next asked if their research on the Internet has ever helped them to feel more supported or reassured in their role as (future) mothers and feel less alone, stressed, anxious or tired (the possible answers were as follows: not at all, a little, very, totally or “I do not feel concerned/I never did this kind of research on the Internet). Women were also asked if they experienced any stressful events during their pregnancy or since their delivery.

In addition, 3 validated questionnaires also evaluated the need for psychological support: the Postnatal Perceived Stress Inventory (PNPSI) for women who had already given birth [22] or the Antenatal Perceived Stress Inventory (APSI) for pregnant women [23], the Edinburg Postnatal Depression Scale (EPDS) [24] and the State-Trait Anxiety Inventory (STAI-Y1 SCALE) [25]. Finally, a fourth questionnaire (the Social Support Questionnaire; SSQ6) was also administered [26].

**Need to share experiences**

Mothers were then asked whether they felt the need to talk about their feelings around them and with whom they talked. They were asked, on a scale from 0 to 10, if they felt understood by the people they talked to about their feelings. The questionnaire also inquired whether mothers would like to talk more or less about their feelings and whether their research on the Internet had ever helped them talk further about it. Mothers were also asked whether they needed to talk with their friends, relatives or health professionals about the information they found on the Internet.

Mothers were next asked if they engaged in any hobbies or activities enabling them to take a break from parenting (the possible answers were as follows: not at all, not enough, enough, too much) and if their research on the Internet had already helped them to find these kinds of activities. If women had ever given birth, they were also asked if they went back to work. If they answered “yes”, the questionnaire inquired about their experiences, whether they were afraid prior to their return to work, and if their research on the Internet had helped them prepare for their return to work. If they answered “no”, the questionnaire only inquired if they were afraid to go back to work and if their research on the Internet had helped them to prepare for it.

**Need for practical and material support**

Mothers were then asked, on a scale from 0 to 10, if they felt supported in their housework and if they felt the need for help in completing their housework (the possible answers were as follows: much more, little
more, enough, a little less, much less). If they said that they felt the need for help, a list of the more current housework was provided to the respondents, and they noted the tasks with which they needed help. The questionnaire also inquired whether anyone had already spontaneously proposed to help with housework, whether the women had already asked for help, and whether their research on the Internet had ever helped them in asking for help with housework.

**Promotion of the study and recruitment**

Online questionnaires were widely distributed, and once a woman responded to the questionnaire, she was enrolled in the study. Each time a woman replied to the survey, her answers appeared directly in the online database. The recruitment methods are described elsewhere (article under submission). In summary, the recruitment of participants was performed in various ways. On the one hand, the study was widely publicized on various websites and on diverse dedicated Facebook pages. In addition, an internal mail was sent twice to all members of the University of Liège – all specialties combined – to disseminate information about the study. On the other hand, in an effort to recruit participants who did not have access to the Internet, flyers were placed in different stores for mothers and/or children. The study was also promoted by word of mouth – by mothers as well as by health professionals and early childhood professionals serving mothers of children aged 0 to 2 years – allowing for a wider dissemination of the study. The study was promoted between August 7, 2017, and October 23, 2017, and was free.

**Data analysis**

A Shapiro-Wilk test verified the normal distribution of all parameters and permitted the application of either parametric statistics or nonparametric statistics tests. All the data did not follow the normal distribution, but to provide a better understanding, all the quantitative variables are expressed as the mean ± standard deviation (SD), and qualitative variables are reported as relative (%) and absolute (n) frequencies. The evaluation of the participants’ demographic, pregnancy and postnatal profiles and the evaluation of each mother’s needs were realized by descriptive statistics. Chi-square and Mann–Whitney U tests facilitated the comparison of all these variables between pregnant women and women who had already given birth but also between primiparous and multiparous women. The analyses were executed with the software Statistica 13.3. The results were considered statistically significant when the 2-tailed p-values were less than 0.05.

**Results**

**Participants and sociodemographic characteristics**

A total of 425 participations (out of 544 inscriptions) were eligible for the study at T0: 132 pregnant women and 293 women who had already given birth. Women were between 18 and 44 years old, and 48.7% of them were primiparous. The participants’ demographic, pregnancy and postnatal profiles are presented in Table 1. There was no significant profile difference between pregnant women and women who had already given birth except for professional status and pregnancy care by an independent
midwife. The only sociodemographic difference between primiparous and multiparous women was their age: primiparous women were logically younger than multiparous women. Among the primiparous and multiparous women, there were as many pregnant women (32.9% vs. 29.4%, respectively) as there were women who had already given birth (67.1% vs. 70.6%, respectively; p = 0.44). There were also many differences in their pregnancy and postnatal profiles.

**Exploration of needs**

**Need for information**

The need for information was widely present in the population: 95.7% of participants reported needing to search for information at least once during pregnancy and/or after delivery. The majority of the pregnant women (92.4%) and the new mothers (90.1%) admitted seeking information about the pregnancy. After childbirth, many new mothers (84.6%) also reported seeking information about themselves or about their baby (65.4% both for themselves and the baby, 16.4% for the baby only, and 2.74% for themselves only). However, this need seemed to be significantly greater in pregnant women (92.4%) than in mothers (84.6%, p = 0.03). The need for information is also significantly greater in primiparous (96.6%) than in multiparous women (78.0%; p < 0.0001). The majority of women who seek information (91.4%) reported that they used the Internet to perform their research, whether it was during or after the pregnancy (p = 0.18) or whether it was their first child or not (p = 0.87). Nevertheless, women seem to search for information significantly (p < 0.0001) more frequently on the Internet after giving birth (54.8% reported “very often” or “daily”) than during pregnancy (41.2% reported “very often” or “daily”). The same observation can be made between primiparous (61.8%) and multiparous women (39.5%; p < 0.001). Women judged the search for information on the Internet in a similar manner (i.e., ease of accessing information, quality of the information, utility of information), whether they were pregnant or had already given birth or whether that it was their first child or not (p > 0.05). Finally, primiparous women were significantly more interested in the recommendation of reliable websites by professionals (80.5%) than were multiparous ones (69.4%; p = 0.01). This last need was similar between pregnant women and mothers (p = 0.47).

**Need for psychological support**

Women generally seemed to be quite satisfied with the support they received. They attributed an average score of 7.70 ± 2.17/10 to the support provided by their partner, 7.42 ± 2.31/10 to the support provided by their family and 7.28 ± 2.19/10 to the support provided by their friends. However, this feeling weakened during the postpartum period. On the one hand, after giving birth, women gave lower ratings to the support they received from their family (p = 0.05) and their friends (p = 0.01) than did pregnant women. In addition, they assigned an average score of 7.12 ± 2.17/10 when they had to rate the relationship they had with their partner, while pregnant women rated it with a mean score of 7.94 ± 1.73/10 (p < 0.0001). Moreover, the social support scores regarding availability (20.6 ± 10.5/54 vs. 23.7 ± 11.5/54) and satisfaction (28.5 ± 6.16/36 vs. 30.1 ± 5.38/36) were significantly higher during pregnancy than during the postpartum period (p = 0.01). On the other hand, multiparous women also felt generally less
supported than did primiparous women, whether by their companion (p = 0.01), their friends (p = 0.01) or their family (p < 0.001). The social support scores regarding availability (23.5 ± 10.7/54 vs. 19.2 ± 10.8/54; p < 0.001) and satisfaction (30.0 ± 5.21/36 vs. 28.1 ± 6.47/36; p = 0.01) were also significantly higher among primiparous women than among multiparous women.

Additionally, feelings of loneliness were higher during the postpartum period than during pregnancy (3.35 ± 2.67/10 vs. 2.25 ± 2.46/10; p < 0.0001). Furthermore, depression scores (9.63 ± 5.53/30 vs. 8.19 ± 5.45/30; p = 0.01) were significantly higher during the postpartum period than during pregnancy. Finally, primiparous women felt less reassured in their roles as mothers than did multiparous women (p < 0.0001), and only after childbirth were the stress scores higher in primiparous women than in multiparous women (p < 0.0001).

**Need to share experiences**

The majority of women (97.4%) said that they talk about their feelings with their relatives or with professionals (53.4% "sometimes", 33.3% "often" and 10.9% "very often"). The need to share experiences thus seemed to be present among both pregnant women and mothers (p = 0.50) but seemed to be more present among primiparous than among multiparous women (p = 0.04). Sources of sharing experiences are different between groups: not surprisingly, pregnant women discussed more with midwives and gynecologists than did mothers (p < 0.0001); primiparous women discussed more with their family (p = 0.001) and with friends without children (p = 0.002) than did multiparous women; and multiparous women also consulted more mothers on forums or Facebook groups (p = 0.03). When women shared their feelings, they tended to think that people around them understand them (7.76 ± 1.74/10) whether it was during pregnancy or after childbirth (p = 0.10) or whether they were mothers for the first time or not (0.62). However, many women would have liked to have the opportunity to talk more about their feelings, and this need seems to be more pronounced in the postpartum period (47.6%) than during pregnancy (30.6%, p = 0.01). Compared to pregnant and primiparous women, respectively, postpartum (84.6% vs. 62.6%, p < 0.0001) and multiparous women (84.4% vs. 70.7%; p = 0.005) believed that they did not have enough leisure activities.

**Need for practical and material support**

Women gave a mean score of 6.04 ± 2.69/10 in feeling supported in their household chores, whether during or after pregnancy (p = 0.11) or whether they were mothers for the first time or not (p = 0.40). The need for practical support therefore seems to be present around the time of birth, and it seems to be even more pronounced during the postpartum period than during pregnancy. Indeed, women who gave birth (72.5%) would like to have more help with housework chores than pregnant women (80.9%; p = 0.01) and for more types of housework chores (4.45 ± 2.54 vs. 3.92 ± 2.79; p = 0.047). Women often did not dare to seek the help they needed, and it seemed that the mothers’ relatives offered their help significantly more often to pregnant women (81.7%) than to new mothers (71.8%, p = 0.02) or to primiparous women (80.0%) than to multiparous women (70.0%; p = 0.04).
Discussion

The aims of this study were to identify maternal needs by comparing the needs of mothers with those of pregnant women and by comparing the needs of primiparous women with those of multiparous women.

The need for information is largely present around the time of birth, and this need has already been proven in several studies [27–30]. This need seemed to be more present during pregnancy than during the postpartum period. Nevertheless, women used the Internet significantly more often to search for information after childbirth than during pregnancy. Regarding the results of our previous study [10], this finding may not be so surprising. Indeed, although the need for information is more important during pregnancy, it is still important after childbirth. However, professionals are aware of the important need for information during pregnancy, but they believe that this need disappears after delivery [10]. It is therefore not surprising that the efforts of professionals are more concentrated during pregnancy. Thus, mothers may feel left out after giving birth and turn to the Internet to bridge gaps. This hypothesis is supported by the difference in information sources, showing that pregnant women discussed significantly more information with midwives and gynecologists than did mothers. The need for information also seemed to be more important in primiparous than in multiparous women. Some studies showed that new mothers (having their first baby) felt unprepared for motherhood [4, 28, 31]. They fluently searched for reliable and realistic information [27, 30] and appreciated having testimonials from other mothers with which they could compare their experiences [10] and appease their fears and anxieties [17].

The need for psychological support seemed to be more important after childbirth than before childbirth. Indeed, even if the global satisfaction with psychological support was fairly good, it weakened after childbirth. Feelings of loneliness and depression scores were also higher during the postpartum period than during pregnancy. Some studies have already highlighted the social upheavals that the arrival of a child generates [3, 4]. In addition, the process of motherhood is described by some authors as a period of identity crisis that can be compared to adolescence by the movement it imposes on the women's personality [32, 33]. It is therefore not surprising that women need to be surrounded and supported by people they consider to be important around them [18, 19]. Not surprisingly, primiparous women felt less reassured in their roles as mothers and more stress during the postpartum period than did multiparous women. Indeed, some studies showed that women, especially primiparous ones, are concerned with the safety of their baby and lack confidence in themselves, especially in the beginning of the motherhood process [17, 34]. As the primiparous women expressed more difficulties, it is not surprising that primiparous women perceived better support from their relatives than did multiparous women. Another hypothesis could be found in the fact that primiparous women are younger and have more leisure activities than multiparous women: they could have more active social lives and therefore more people present to help or support them.

Thus, the needs for psychological support and to share experiences seemed to be closely linked. Sharing experiences seem to be a form of psychological support. Indeed, mothers like to have the possibility of discussing what they experience, especially with other mothers, to determine if what they are experiencing
is normal [10]. The concept of normality seems very important in this period of life. Sharing experiences helps mothers to address this fear of abnormality. This step seems to be very important in the appropriation of the role of a mother. Women need empathy and to be understood. Moreover, this study showed that more women would like to have the opportunity to talk more about their feelings during the postpartum period than during the pregnancy. Once again, this study highlighted the importance of social support around a birth [35–38].

The need for practical support is also present around a birth, and it seems to be more pronounced during the postpartum period than during pregnancy. Indeed, housework chores are indispensable, but it seems to be a considerable challenge for mothers [10, 35, 39]. Already tired and worried about the management of their child, mothers would like more help in household management, at least in the first weeks after childbirth, to have the time to adapt themselves to their new situation [35, 40]. There was no difference in the need for practical support between primiparous and multiparous women. However, it seemed that the mothers’ relatives offered their help significantly more often to primiparous than to multiparous women. This could be due to the higher level of social support expressed by primiparous women.

**Implications for practice**

There is a discrepancy between the professionals’ perception of maternal needs and the needs felt by mothers [10]. Indeed, professionals seem to be more concerned about the needs during pregnancy than during the postpartum period. However, this study and many other studies showed that mothers present important physical and emotional needs during the postpartum period [3, 4, 31, 33, 35, 39–45, 10, 46, 17–19, 27–30]. Thus, the promotion of maternal health by professionals cannot end at the birth of the newborn [40]. For a healthy postnatal period, women must use their own skills to ensure that their needs and those of their family are met [40]. Postnatal care providers therefore must help women find necessary resources to develop the required skills to appropriately meet their needs. They must respect a holistic vision of maternal health promotion, especially in the context of shortened maternity leave [47, 48].

**Strengths and limitations**

To our knowledge, this is the first to study maternal needs during the postpartum period by comparing needs during and after pregnancy. This study also suggests differences in the needs between primiparous and multiparous women. Additionally, this study is a continuation of a qualitative investigation of the mothers’ needs. The qualitative method was well adapted to explore the mothers’ needs and to obtain very rich results. However, qualitative methods did not allow for the measurement of the frequency or the extent to which mothers felt these needs. A quantitative investigation was therefore necessary to complete the mothers’ needs exploration.

This study also presented some possible limitations. This survey used a self-report questionnaire that induced all the estimation errors that such a questionnaire can cause [49]. This study used a web survey, and we could not record the number of nonparticipants to the survey. Moreover, the present study only investigated the needs of mothers who gave birth to healthy term babies. The representativeness of the
respondents therefore cannot be asserted for all mothers in Belgium. Nevertheless, the survey was available on many websites and social networks to reach a large number of Belgian mothers (n = 425), and the results seemed to correspond with those of other studies conducted during pregnancy. Indeed, a recent systematic review sowed that there is growing evidence to suggest that Facebook is a useful recruitment tool and that its use should be considered when implementing health research [50]. It seems to reduce costs and recruitment periods but also to provide a better representation of the population in comparison with traditional recruitment methods (print, radio, television, and email).

**Conclusion**

The postnatal period can be described as a period of identity crisis in which mothers must address new needs. This study allowed us to validate, on a large scale, the 4 categories of needs identifying earlier in our previous study [10]: needs for information, for psychological support, for the sharing of experiences and for practical and material support. All mothers seem to experience these needs during the postpartum period but at different levels of intensity. For example, the needs of primiparous women are generally more intensive and less specific than the needs of multiparous women. This study helps to clarify what mothers experience after childbirth. Trying to meet these needs could offer an opportunity to improve the quality of life of mothers and to prevent the risk of psychological distress that may occur after childbirth.

**Declarations**

**Acknowledgements**

I would like to thank everyone who participated in this study, particularly all the women who responded to the survey.

**Funding**

None.

**Availability of data and materials**

The dataset on which the conclusions of this manuscript rely will not be made available given the conditions stated in the written informed consent form to protect the identity of the participants.

**Authors’ contributions**

JS, OB, PE and JYR conceived the study and developed hypotheses and protocol. JS conceived the survey questionnaires with the approval of OB, PE et JYR and JS was responsible for data collection. JS were responsible for data management and data analyses. JS wrote the drafts of the article under the supervision of OB and PE. All authors have read, reviewed and approved the final manuscript.

**Ethics approval and consent to participate**
The study was approved by the “Comité d'Ethique Hospitalo-Facultaire Universitaire de Liège”, under the number 2017/14. A complete written description of the research, including intends to publish, was provided to the participant at the beginning of the first questionnaire. Participation in the study was therefore considered to indicate the consent of the respondent. The email addresses of the participants were necessary to be able to contact them for the second part of the study. Participation in the survey was therefore confidential.

**Consent for publication**

Not applicable.

**Competing interests**

The authors declare that they have no conflict of interests.
